

Über dieses Buch

Dies ist ein digitales Exemplar eines Buches, das seit Generationen in den Regalen der Bibliotheken aufbewahrt wurde, bevor es von Google im Rahmen eines Projekts, mit dem die Bücher dieser Welt online verfügbar gemacht werden sollen, sorgfältig gescannt wurde.

Das Buch hat das Urheberrecht überdauert und kann nun öffentlich zugänglich gemacht werden. Ein öffentlich zugängliches Buch ist ein Buch, das niemals Urheberrechten unterlag oder bei dem die Schutzfrist des Urheberrechts abgelaufen ist. Ob ein Buch öffentlich zugänglich ist, kann von Land zu Land unterschiedlich sein. Öffentlich zugängliche Bücher sind unser Tor zur Vergangenheit und stellen ein geschichtliches, kulturelles und wissenschaftliches Vermögen dar, das häufig nur schwierig zu entdecken ist.

Gebrauchsspuren, Anmerkungen und andere Randbemerkungen, die im Originalband enthalten sind, finden sich auch in dieser Datei – eine Erinnerung an die lange Reise, die das Buch vom Verleger zu einer Bibliothek und weiter zu Ihnen hinter sich gebracht hat.

Nutzungsrichtlinien

Google ist stolz, mit Bibliotheken in partnerschaftlicher Zusammenarbeit öffentlich zugängliches Material zu digitalisieren und einer breiten Masse zugänglich zu machen. Öffentlich zugängliche Bücher gehören der Öffentlichkeit, und wir sind nur ihre Hüter. Nichtsdestotrotz ist diese Arbeit kostspielig. Um diese Ressource weiterhin zur Verfügung stellen zu können, haben wir Schritte unternommen, um den Missbrauch durch kommerzielle Parteien zu verhindern. Dazu gehören technische Einschränkungen für automatisierte Abfragen.

Wir bitten Sie um Einhaltung folgender Richtlinien:

- + *Nutzung der Dateien zu nichtkommerziellen Zwecken* Wir haben Google Buchsuche für Endanwender konzipiert und möchten, dass Sie diese Dateien nur für persönliche, nichtkommerzielle Zwecke verwenden.
- + *Keine automatisierten Abfragen* Senden Sie keine automatisierten Abfragen irgendwelcher Art an das Google-System. Wenn Sie Recherchen über maschinelle Übersetzung, optische Zeichenerkennung oder andere Bereiche durchführen, in denen der Zugang zu Text in großen Mengen nützlich ist, wenden Sie sich bitte an uns. Wir fördern die Nutzung des öffentlich zugänglichen Materials für diese Zwecke und können Ihnen unter Umständen helfen.
- + *Beibehaltung von Google-Markenelementen* Das "Wasserzeichen" von Google, das Sie in jeder Datei finden, ist wichtig zur Information über dieses Projekt und hilft den Anwendern weiteres Material über Google Buchsuche zu finden. Bitte entfernen Sie das Wasserzeichen nicht.
- + *Bewegen Sie sich innerhalb der Legalität* Unabhängig von Ihrem Verwendungszweck müssen Sie sich Ihrer Verantwortung bewusst sein, sicherzustellen, dass Ihre Nutzung legal ist. Gehen Sie nicht davon aus, dass ein Buch, das nach unserem Dafürhalten für Nutzer in den USA öffentlich zugänglich ist, auch für Nutzer in anderen Ländern öffentlich zugänglich ist. Ob ein Buch noch dem Urheberrecht unterliegt, ist von Land zu Land verschieden. Wir können keine Beratung leisten, ob eine bestimmte Nutzung eines bestimmten Buches gesetzlich zulässig ist. Gehen Sie nicht davon aus, dass das Erscheinen eines Buchs in Google Buchsuche bedeutet, dass es in jeder Form und überall auf der Welt verwendet werden kann. Eine Urheberrechtsverletzung kann schwerwiegende Folgen haben.

Über Google Buchsuche

Das Ziel von Google besteht darin, die weltweiten Informationen zu organisieren und allgemein nutzbar und zugänglich zu machen. Google Buchsuche hilft Lesern dabei, die Bücher dieser Welt zu entdecken, und unterstützt Autoren und Verleger dabei, neue Zielgruppen zu erreichen. Den gesamten Buchtext können Sie im Internet unter <http://books.google.com> durchsuchen.

This is a reproduction of a library book that was digitized by Google as part of an ongoing effort to preserve the information in books and make it universally accessible.

Original Communications.

A COUNTRY HERBALIST'S CURE FOR THE "KING'S EVIL" (a)

By JOHN KNOTT, M.A., M.D., and Dip. Stat. Med. (Univ. Dub.); M.R.C.P.I.; M.R.I.A.; &c., &c.

THE comparatively trivial nature of the communication which I have had the temerity to bring under the notice of the Medical Section of our Academy can, perhaps, be best excused by suggesting its usefulness as an item provided for the mental relaxation of my hearers in the interval between the periods of intellectual digestion of the more ponderous courses which are usually supplied. The details of the remedy in question were not, as the title of this paper might mislead some to think, obtained from a profound "herbalist" or pharmacologist of any kind. The only connection which my informant had with the profession of healing, in addition to the practice of his "cure," was by forming the last link of the chain—in the capacity of grave-digger. He exercised the function of sexton of a parish church in my native county of Roscommon, close to the bordering Shannon, which separates it from the adjacent county of Leitrim. The quiet, wavy, hilly-hollow, emerald-clad fields of this locality have reflected the first light on some of the most enlightened and enlightening members of our profession. Within a very short distance of the churchyard where my sexton friend cures and buries his neighbours, was born my friend, Dr. Michael F. Cox, one of the highest living authorities on Irish history and antiquities, and who will, I trust, throw some additional light on the folklore medicine of the locality. Hard by the birthplace of the latter, our native western air was first breathed by him whose "brief, brave, and glorious young career" was so recently unexpectedly terminated, and whose place will long remain unfilled in the breasts of those who were privileged to enjoy the intimate friendship of Thomas Heazle Parke. Close to the same place lived and died the maternal grandparents of that inspired member of our profession, who, of all that our country has produced, has secured the firmest hold on future immortality. Those who know anything of Irish country life are aware how very usual it was for a married lady to go to her mother's home to pass through the trying period of her parturition; and, in accordance with this custom, local tradition states, and—from its nature and origin—I believe, with absolute accuracy, that in the same parish where my friend practised his herbal cure was born one of the brightest ornaments of the world's literature and of the medical profession. The misleading information supplied by speculative biographers and hackney journalists will probably not have prepared the majority of those present for what should send a thrill through the breast of every one of my hearers, when I mention the honoured name of Oliver Goldsmith.

I made the acquaintance of my "herbalist" friend as he was engaged in his customary vocation of digging a grave—for, I was told, a girl of about nineteen,

who had died from a gradual "decline" caused by the discharge from a number of "running evils," which had developed in the neck and various parts of the limbs. I visited the place in company with the incumbent of the parish, who introduced me to his adjutant; and who, being of a jocular disposition, made some remarks on the accidental meeting of two professors of the healing art, and quizzed the sexton by observing that his present task might have been indefinitely postponed—if the friends of the poor victim of early decline had been judicious enough to avail themselves of his services in his other capacity. This led to further conversation, and ultimately to the friendly communication to me of a description of his treatment of the "King's Evil." His "cure" was carried out in three stages:—

1. The "sore" was poulticed with a preparation of the leaves of the "cuckoo sorrel."
2. The "dressing" consisted of a preparation of the root of the "sweetmeadow."
3. Application of a "plaster" compound of
Beeswax,
Sheep suet,
Yolk of egg,
First flour.

The leaves of the cuckoo-sorrel were gathered when rich in sap, placed in a saucepan on the fire, and "*stewed in their own sap*," by being continuously crushed and squeezed in various directions, and moved about so as to prevent their sticking to the bottom or sides of the saucepan and getting burnt. When reduced by this process to a somewhat jelly-like mass, the latter was spread "even" on a piece of calico or linen cloth, and applied to the sore. The application was always a very painful one.

When the sore was fairly "cleansed" by repeated applications of this dressing, the first stage of the cure was considered complete. The root of the sweet meadow was then procured: "the present year's growth—soft and mellow"—was always employed. It was carefully scraped so as to free it from all particles of adhering earth, and then thoroughly pounded so as to bring it to a pretty uniform consistence. This was also spread on a cloth, after having received on its surface a layer of the richest cream; which, in turn, was varnished by a coating of the "scum from the churn-cup."

The belief of the efficacy of this cure for the otherwise so unmanageable King's Evil was strongly corroborated by local testimony, and excited my curiosity to investigate on my return home the previous therapeutic history of the plants named—if they had any.

Accordingly, I was greatly interested in finding this Irish rural remedy for "scrophulous ulcers" mentioned by Dr. Beddoes in his work "On the Medical Use and Production of Factitious Airs," and quoted from him by Dr. Thomas Winterbottom, Physician to the colony of Sierra Leone, who points out its similarity to a "cure for ulcers" which he had found "used by the people about Bassa, on the Grain Coast." The Irish remedy "is composed of leaves and stalks of wood-sorrel (*oxalis acetosella*) and the root of meadow sweet (*spirea ulmaria*)."
The application is thus described by Dr. Beddoes: "The sorrel is prepared by wrapping it in a cabbage leaf and macerating it by its

(a) An abstract of this paper was read in the Medical Section of the Royal Academy of Medicine in Ireland on Nov. 18th, 1898.

own juices in warm peat ashes. This pulp is applied as a poultice to the ulcers, and left twenty-four hours; the application of sorrel is four times repeated; then the roots of the meadow sweet, bruised and mixed with the sour-head or efflorescence that appears on buttermilk left in the churn, and used in the same manner till the sore heals, which always speedily happens, often in two or three weeks."

Dr. Winterbottom's account of the corresponding surgical remedy of the aboriginal African tribe is as follows:—"The leaves of the amelliky are used by the people about Bassa, on the Grain coast, in the cure of ulcers. The young leaves, after being moistened in water, are wrapped in a piece of plantain leaf, and laid upon hot ashes; when thoroughly warmed they are taken out, and their juice is pressed out upon the sore, which is then covered with a piece of plantain leaf made hot in the fire; the juice is of a brownish colour, of a slightly acid and astringent taste. *I saw it effectual in a small, obstinate, ill-looking ulcer, which had resisted every other application.* [The italics are mine.]

Subsequent research showed me that the herbs in question had, respectively, enjoyed high pharmacological reputations down to about the middle of the present century; when, like many others of venerable fame, they were retired to make room for junior competitors. In the interesting work of Roques, *Plantes Usuelles, Indigenes et Exotiques* (Paris, 1808), I find the following notice of the common sorrell.

Oseille (Rumex Acetosa).—"Desbois de Rochefort a parlé avec enthousiasme des propriétés de l'Oseille. Selon lui, les fièvres intermittentes qui ont résisté aux amers et au quinquina, cedent, comme par enchantement, à l'usage de cette plante, surtout s'il existe des symptômes scorbutiques."

In Woodward's *Medical Botany* (2nd edition, London, 1810), is the following notice, which proves that its value was then appreciated in Great Britain:—

"The *Acetosella* is totally inodorous, but has a grateful acid taste, which is more agreeable than the common sorrel (*Rumex Acetosa*), and approaches nearly to that of the juice of lemons, or the acid of tartar, with which it also corresponds in a great measure in its medical effects, being esteemed refrigerant, antiscorbutic, and diuretic. It is recommended by Bergius in inflammation, bilious and putrid fevers, and from the cases adduced by Francus, he concludes, '*Acetossellam appetitum restaurare, vomitum conspire, alvum stringere, sitim sedare, oris amaritatem tollere, cordis vires reparare, anginam abigere.*' The principal use, however, of the *Acetosella*, is to allay inordinate heat, and to quench thirst; for this purpose a pleasant whey may be formed by boiling the plant in milk, which, under certain circumstances, may be preferable to the conserve directed by the London College, though an extremely grateful and useful medicine. Many have employed the root of Lujula, probably on account of its beautiful red colour rather than its superior efficacy. An essential salt is prepared from this plant, known by the name of Essential Salt of Lemons, and commonly used for taking ink-stains out of linen."

In the *Medical Botany* by Stephenson and Churchill (new edition by Gilbert and Burnett, London, 1834), we read:—"Wood-sorrel is inodorous, but possesses a very agreeable and refreshing acid taste. Twenty pounds of the fresh plant yielded to Newman six pounds of juice, from which he got two ounces, two drams, and one scruple of the bin-oxalate of potash, and two ounces six drams of an impure saline mass. The bin-oxalate of potash is one of three subspecies of oxalate of potash, and exists ready formed in *oxalis acetosella*, *oxalis corniculata*, and different species of *Rumex*, from which it is extracted in some parts of Europe in large quantities. Hence it is

known by the name of salt of wood-sorrel, and in this country is sold as essential salt of lemons, mixed with an equal quantity of cream of tartar. It is mentioned by Duclos in the 'Memoirs of the French Academy for 1668.' Marcgraaf proved that it contained potash, and Scheele discovered its salt to be oxalic. It may be formed, as Scheele has shown, by dropping potash very gradually into a saturated solution of oxalic acid in water; as soon as the proper quantity of alkali is added, the bin-oxalate is precipitated. But care must be taken not to add too much alkali, otherwise no precipitation will take place at all.

"MEDICAL PROPERTIES AND USES.—The leaves of this plant are among the most grateful of the vegetable acids. The juice of sorrel is sometimes used as an agreeable refreshing drink in fevers, and the leaves boiled in milk form a pleasant whey; but the other vegetable acids are quite as useful and more available. Beaten up with fine sugar, the leaves make a refreshing and wholesome conserve; 'its flavour resembling green tea.' The leaves in a recent state form a good salad for the scorbutic, and have been employed with advantage as an external application to scrofulous ulcers." So that we have more than ample evidence to demonstrate the appreciation of the therapeutic value of the sorrel family in the first half of the nineteenth century.

An additional interest is superadded for us Irishmen in the fact that it has been claimed by a high botanical authority that the wood-sorrel is really the genuine original *shamrock* of St. Patrick. On this subject, Mr. Bichene, the secretary of the Linnæan Society, read a paper on the appropriate date of St. Patrick's Eve, 1830. An abstract appeared in the *Philosophical Magazine* of the following June: He stated that it would seem "a condition at least suitable if not necessary to a national emblem that it should be something familiar to the people, and familiar, too, at that season when the national feast was celebrated. Thus the Welsh have given the *Leek* to St. David, being a favourite oleraceous herb, and the only green thing they could find on the 1st of March; the Scotch, on the other hand, whose feast is in autumn, have adopted the *Thistle*. The white clover is not fully expanded on St. Patrick's Day, and wild specimens of it could hardly be obtained at this season. Besides, it was probably, nay, almost certainly, a plant of uncommon occurrence in Ireland during its early history, having been introduced into that country in the middle of the seventeenth century, and made common by cultivation. He then referred to several old authors to prove that the *Shamrock* was eaten by the Irish, and to one who went over to Ireland in the sixteenth century, who says it was eaten and was a *sour* plant. The name also of *Shamrock* is common to several trefoils, both in the Irish and Gaelic languages. Now clover could not have been eaten, and it is not sour. Taking therefore all the conditions requisite, they are only found in the wood-sorrel, *Oxalis acetosella*. It is an early spring plant; it was and is abundant in Ireland; it is a trefoil; it is called *Sham-rog* by the old herbalists; and it is sour; while its beauty might well entitle it to the distinction of being the national emblem. The substitution of one for the other has been occasioned by cultivation which made the wood-sorrel less plentiful, and the Dutch clover abundant."

In passing backwards to the voluminous *Herbals* of former centuries, we find copious notices of the great therapeutic virtues and multitudinous preparations of this plant and its numerous cousins.

In the *Theatrum Botanicum* (1640), Parkinson describes no less than fifteen varieties of *Acetosa*, and gives the following general account of the whole:—

"*The Names.*—It is called in Greeke *ῥαῖς*, *oxalis* of the sharpe taste, many of the Latine writers keepe that name, in Latine also *Acetosa*, and of some *Ac-*

dula of the sournesse thereof; others call it *Rumex hortensis*, and Galen calleth it *δύλακας*, id est, *Lapathum acidum*, soure Docke, yett with *Dioscorides*, *Oxalaphathum* is *Lapathum Acutum*, that kinde of Docke whose forme of leafe is more sharpe and pointed then others, and not for the sharpe taste to cause that name, the Sheepes Sorrel, is called *Lapathium* and *Acetosella* by divers. *Clusius* maketh mention of the first great sort, and *Lobel* of the second, *Dodonæus*, and *Lobel* gave first of all others knowledge of the third, and *Columna* of the fourth; *Bauhinus* of the fift sixt, and seventh, *Columna* of the eight, *Prosper Alpinus* in his Booke of *Egyptian* plants of the ninth; of the tenth and last none hath made any mention: now *Besterus* in horto *Eystetensi* speaketh of the eleventh, by the name of *Acetosa vesicaria peregrina*, which *Bauhinus* calleth *Acetosa Americana foliis longissimis pediculis donatis*; but of the twelfth sort (if it be not the same with the second, whereunto it is very like), no author ever made mention before now, and scarce is it known to any but the gentleman of *Anglsey*, called Mr. *Morris Lloyd*, of *Prislerworth*, that found it on a mountaine in Wales, and showed it to Dr. *Bonham* in his life; the thirteenth is called by *Matthiolus Tenuifolia*; and so by *Lonicus*, *Gesner*, *Tragus*, and almost all other writers of herbes in our later age, and called *Oxalis vervecina* of *Lobel* and *Orina* of others, and *arvensis lanceolata* by *Bauhinus*; the fourteenth is remembered by *Montanus*, *Gerard*, and *Bauhinus*. All of them deservedly have the name of Sorrell, because howsoever, they are somewhat different in leafe or roote yett they all agree in the sournesse, although some more or lesse then others. The *Arabians*, as *Serapio* saith, call it *Humaalh*; the *Italians* *Acetosa*, the *Spaniards* *Azedera*, *Azederilha* and *Agrethus*; the *French* *Azeille* or *Oseille*, *Saltette*, *Surette*, and *Aigrette*; the *Germanes* *Sawrampfer*; the *Dutch* *Surckle* and *Surincke*; and we in *English* Sorrell.

The Virtues.—Sorrell is cooling and drying in the second degree, and is prevalent in all hot diseases to coole any inflammation and heate of bloud in agues pestilentiall or chollericke, or other sicknesses and fainting rising from heate, and to refresh the overspent spirits with the violence of furious or fiery fits of agues, &c., to quench thirst, and to procure an appetite in fainting or decayed stomackes; for it resisteth the putrefaction of the bloud, killeth wormes, and is a cordiall to the heart which the seede doth more effectually, being more drying and binding, and thereby also stayeth the hot fluxes of the menstrues, or of humours in the bloudy fixe, or fluxe of the stomacke; the roote also in a decoction or in powder, is effectuell for the said purposes; both rootes and seede, as well as the herbe is held powerfull to resist the poison of the scorpion, so that he that shall eat thereof shall feele no paine being stung; the decoction of the rootes is taken to helpe the jaundise, and to expel gravell, and the stone in the ruines or kidneys; the decoction of the flowers made with wine and drunke helpeth the blacke jaundise, as also the inward ulcers of the body or bowells.

"A syrupe made with the juyce of Sorrel and Fumiterie is a soveraine helpe to kill the force of those sharpe humours that cause the itch: the juyce thereof with a little Vinegar, serveth well to use outwardly for the same cause, and is also profitable for frettings and gallings of the skin in any part, and for tetter, ringwormes, &c. It helpeth also to discusse the scrophules or kernells in the throate, and the juyce gargled in the mouth helpeth the sores therein: the leaves wrapped up in a Colewort leafe, and roasted under the Embers, and applied to an hard empostume, botch, bile, or plague sore, both ripeneth

and breaketh it: the juyce of Sorrell dropped into the eares of such as are hard of hearing helpeth oftentimes: the distilled water of the herbe is of much good use for all the purposes aforesaid. The lesser Wilde Sorrell, and so all the other are of the same qualitie, and are no lesse effectuell in all the diseases before spoken of."

The Wood Sorrell is treated separately in the following chapter, which I accordingly quote in its entirety:—

"*Oxys, Alleluja sive Trifolium Acetosum.*

"There are two sorts of Wood Sorrell, the one familiar enough in many places of this land, the other a stranger, as farre as I can learne, and onely cherished in the gardens of those that are curious. I have, as I said, brought these two sorts from their family, where they might otherwise be ranked that is among the Trefoiles for their propertie and name also, in part.

"1. *Trifolium Acetosum Vulgare*, Common Wood Sorrell.—The common Wood Sorrell groweth low upon the ground without any stalke rising from it, having a number of leaves comming from the roote made of three leaves like a trefoile or three-leaved grasse, but broad at the ends, and cut in the middle, of a faint yellowish greene colour, every one standing on a big footestalke, which at their first comming up are close folded together to the stalke, but opening themselves afterwards, and are of a fine sour relish, more pleasing then many of the former Sorrells, and yielding a juyce, which will turne red when it is clarified, and maketh a most daintie cleare syrupe: among these leaves rise up divers slender weake foote stalkes, not growing above them, with every one of them a flower at the top, consisting of five small and pointed leaves starre fashion, of a white colour in most places, or in some dasht over with a shew of blush, and in some but on the backe side onely; of any other colour (although some have set downe that it beareth deepe coloured flowers) I have not seene, after the flowers are past follow small round heads, with small yellowish seede in them: the rootes are nothing but threads or small strings fastened to the end of a small long piece, all of them being of a yellowish colour not perishing every year, but abiding with some leaves thereon in the Winter.

"2. *Oxys luteo flore*.—Wood Sorrel with yellow flowers. This Wood Sorrel shooteth forth divers slender weak reddish stalks trailing upon the ground, and taking root at the joints as they lie, spread into many branches, with many leaves on them, standing singly one above another and made of 3 leaves cut in at the ends like the former, but are much smaller and of a paler greene colour; at the joynts with the leaves come forth three or four small flowers together, at the end of a long foote stalke, yett each separate from other, consisting of small and pointed leaves like the other, but contained in smaller and longer heads like cods or hornes, yett not crooked but pointed small which quickly fall away when touched when they are ripe, and spring up againe all about where it grew; it abideth the Winter without perishing, if it be not too violent, else they will rot and perish must be new sowne againe.

The Place.—The first, as I said, groweth plentifully in many places of the land, in woods, and wood sides, where they may be moist and shadowed, and in other places that are not too much open to the sun; the other groweth in divers shadowie places about *Seville* in *Spaine*, and in gardens at *Mompelier*.

The Time.—The first flowereth early in *Aprill* and *May*, the others after *Midsommer*, and so continueth in flower until the *Autume* colds perish it, and the seede is ripe in the meantime.

The Names.—It is generally taken to be the *Oxys* of *Pliny*, whereof he speaketh in his 27. Booke, and

12. Chapter, but not the *Oxytriphylum*, although *Tragus* and *Lacuna* do so call it, because the name did somewhat agree thereto, but that it is another herbe whose sharpe pointed leaves, and not the sharpe taste caused this name, for $\alpha\gamma$ the Greeke word doth signifie both sharpnesse in forme and in taste. It is called *Trifolium acetosum* of divers, which is the same in signification as I said with *Oxytriphylum*, and of some *Panis Cuculi*, Cuckowbreade, eyther because the Cuckowes delight to feede thereon, or that it beginneth to blossom when the Cuckow beginneth to utter her voyce; it is called by the Apothecaries in their shoppes *Alleluja* and *Lujula*, the one because about that time it is in flower when *Alleluja* in antient times was wont to bee sung in the churches, the other came corruptly from *Juliola* as they of *Calabria* in *Naples* doe call it, as *Scaliger* upon *Theophrastus de causis plantarum* saith, yet it is there set downe *Alleluja*, but I think it rather should be *Lujula*. The other is called *Oxys flore luteo* of *Clusius*, and *Oxys lutea corniculata repens* of *Lobel*, and of *Bauhinus* *Trifolium acetosum corniculatum*. The *Italians* call it *Trifolio acetoso Pan cuculi* and *Alleluja*, the *French*, *Pain de coqu*, the *Germans* *Sawerklee*, the *Dutch* *Coeckcoezbroet*, and we in *English* *Wood Sorrell*, *Wood Sower*, *Stabbewort*, and *Sorrell dubois*.

The Virtues.—Wood Sorrell is cold and dry as the other Sorrells are, and serveth to all the purposes that they doe, being as effectually if not more, especially in hindring the putrefaction of blood and ulcers in the mouth and body, and in cooling and tempering distempered heats and inflammations, to quench thirst, to strengthen a weake stomacke, to procure an appetite, to stay vomiting, and most singularly excellent in any contagious sicknesse or pestitentiall Feaver, the syrupe made of the juice is effectually in all the causes aforesaid, and so is the distilled water of the herbe also: Spunges or linnen clothes wet in the juyce and applyed outwardly to any hot tumours and inflammations doth exceedingly coole and helpe them; the same juice taken into the mouth and there gargled for some time, and after spit forth and fresh taken, will wonderfully helpe a stinking, foule Canker or Ulcer therein; it is also singular good in wounds, punctures, thrusts and stabbes into the body, to stay the bleeding and to cleanse and heale the wounds speedily, and helpeth well also to stay any hot defluxions or catarrhes upon the Throat and Lungs."

(To be continued.)

"THE CANCER FOG."

AN ADDRESS DELIVERED AT THE INAUGURAL MEETING OF THE CANCER SOCIETY, JUNE 7, 1899.

By HERBERT SNOW, M.D.Lond., &c.,

Surgeon to the Cancer Hospital since 1876.

SIR CHARLES CAMERON, LADIES AND GENTLEMEN—The discerning student of history quickly observes that no important reform-movement, social, political, or religious, has ever arisen and flourished until the time was thoroughly ripe for it: and secondly, unless it was absolutely necessary. So in briefly considering the reasons which invite the institution of this society, I have to ask in the first place whether it is really required by the community; and secondly, whether the present is a fitting period for its inauguration.

As its printed circular, on the authority of the Registrar-General, informs you, the mortality from cancer is steadily on the increase. In 1864, 8,117

people died from this source; in 1874, 11,011; in 1884, 15,198; in 1894, 21,422. In 1897, the last year for which the returns have been issued, the total was no less than 24,443 (males 9,673, females 14,870).

But of course the population has also increased; and may not these large figures be due to that fact? The supposition is disproved by calculating the ratio of deaths to each million of living persons. In 1864, this was only 385; in 1874, it had risen to 461; in 1884, to 563; in 1895, to 755; in 1896, to 764; in 1897, to 787. You will please note the steadily progressive increase of the ratio, concurrently with that of the population. This, to my mind, suffices to prove the point in question, though an attempt has been made with some dialectical skill to minimise its force, and to show that more people die from cancer simply because more live to an advanced age. Even if such were the case, I am unable to see the pertinence of the argument, for no cancer ever arises merely from age, and *without a definite exciting cause*. Then also it has been said that the figures are larger than in former years, because medical education has improved, and doctors are better able to recognise cancer when they see it. Even if that were so (and I, at least, can hardly regard the argument as serious), it is plain that there has been no commensurate progress in treatment. Lastly, I may fairly ask—without any reference to statistics, which often involve fallacy: "Do we not all daily more and more hear of kinsfolk and acquaintance dying on every side from cancerous maladies?"

It has further been pointed out that a large proportion of the deaths are referable to cancer in such form as, on the common consensus of opinion among all the leading surgeons of the present day, are curable radically and permanently by a surgical operation under certain given conditions. If that be true, we are confronted with one of two alternatives. Either those conditions are difficult of attainment; or else we doctors do our work very badly, and most imperfectly fulfil our functions as guardians of the public health.

Last month a leading medical magazine issued a special "Cancer Number," from which I will quote one or two extracts singularly pertinent to our present purpose:—

"Cancer is the Darkest Africa on the map of medicine. For all of us it has something of the gruesome fascination of a ghost story."

"There is too much individualism in scientific work, and the result is not only waste of power, but actual loss of knowledge; which is allowed to die with its discoverer because he could not get a hearing for it or because it failed to find favour in the eyes of some superior person."

We could hardly find a more trenchant indictment of existing medical organisation for scientific purposes, or a more ingenuous confession that radical reforms are here greatly needed. Yet one more quotation from the same source (*The Practitioner*, April, 1899):—

"With a proper organisation of research on definite lines by a number of investigators working together to a definite end, there would be little or no leakage, and success (i.e., in cancer-research) would be merely a matter of time."

Again, I would fain ask you if it be not a sign of the times, and a note of ominous warning, when we find the President of the College of Surgeons—who is regarded, and justly regarded, as a species of Pope in our profession, and who may not unfairly be described as speaking *ex cathedra* when he delivers the Hunterian Oration before H.R.H. the Prince of Wales—but a few weeks since pointed out the scant progress since the days of John Hunter.

Now, I greatly wish that some competent person would take the trouble to survey, purely from a

philosopher's point of view, the literature of cancer during the past century. He would easily master the special treatises. Excluding pamphlets dealing with one or two counties in a vast empire, and of the more or less scrappy order, only two works on the whole field have appeared within that period, the only two extant in our language. You will please note here the strange contrast presented by those branches of our art in which recent progress has been most marked: *e.g.*, Gynæcology, Ophthalmology, Bacteriology. In each of these he would have a whole library at his disposal. But in the medical journals he will find articles and papers innumerable, often involving laborious toil, profound thought, and continued self-sacrifice in the cause of truth.

Yet, strange to say, the truth always eludes our grasp. The philosopher of whom I speak will find everything moving perpetually round and round in a vicious circle. The great region of cancerous maladies bristles everywhere with moot points and controversial questions, some abstract, but very many, on the other hand, of the most practical and immediate import. Some one takes great pains to determine one of these, and his paper convinces not only himself but all who read it; so that we might reasonably suppose the matter settled for good and all. Yet a few years elapse; the question is found to be as undetermined as ever; and the same process is gone through over again with infinite waste of time and force. Nothing is ever settled. All sorts of views and opinions flourish, the false equally with the true. All is truly "Darkest Africa," or densest London fog.

I appeal confidently to those unprejudiced members of my own profession, whose years and acquirements place them in a position to judge, whether the picture here drawn is at all overwrought. Though seeking to avoid unnecessary technicalities before the present audience, I am constrained to quote as instances what I mean—long-settled points yet remaining matters of dispute even among doctors—the phrases, "Constitutional Origin," "Heredity," "Bacterial Origin," "Geographical Distribution," "Cancer-houses," "Damp Soils," "Vegetarianism," "Electricity." While of the fog outside our profession, the ever-recurring paper questions about the harmless necessary tomato will suffice. Even vaccination, which surely has sins enough already to answer for, at least in the view of its opponents, is gravely proclaimed the true cause of cancer increase, by no less eminent a High Priest of Science than Alfred Russel Wallace!

From the point of view of the logician who has also some smattering of pathology, all the articles in the lay journals upon "Cancer" and 99 per cent. of those in the medical are vitiated by a radical fallacy, which brings the argument to naught. It is the custom to speak of "Cancer" as though it were a single malady; instead of a very wide group of extremely diverse diseases, linked together by a single feature; in most other particulars differing *toto cælo*; and each owning a special exciting cause apart from those which generate the rest.

Why then do these maladies, which we must perforce now discuss under the single word, loom so largely on our mortality registers? And why has Sir William MacCormac to deplore the want of progress in their treatment since John Hunter's epoch? Assuredly not for want of research and of laborious industry by the members of the medical profession; but simply by reason of the *utter absence of co-ordination and organisation*. Hitherto the force of numerous individual workers has been wasted to an enormous extent, and there has been no "Cancer-Science" worthy of the name. And it is the aim of this Society—(I ask you if it be not a grand and worthy aim?)—to create one.

In attaining that object the Society will earnestly endeavour to sink all unworthy jealousy, avoid all class prejudices, elude all side issues which would divert it from its goal. I am informed that not a few persons who received the printed circular seemed to regard this as involving a reflection upon medical practitioners, who are presumed guilty of not doing their level best to grapple with a universal foe, sparing no ranks of society, though most cruelly gripping in its claws the poor and already suffering.

I am assured that nothing could be more remote from the views with which the movement was set on foot, and which the circular aptly expresses. It is hoped to gain the cordial co-operation of the more able and enlightened medical men, of all classes and ranks within their profession in this great reform movement. So by means of their wisdom, zeal and experience, under the magic spell of judicious organisation, and concentration of those scattered efforts which the authority above cited tells us are now wasted solely for want thereof, the Society desires to work. It will sedulously shun conflict with the legitimate authority and opinion of the medical profession at large. It will but seek to strengthen the hands of the members throughout the world, of that profession, and in a quarter where they themselves universally confess the utmost weakness. Of such a spirit and intention the presence on the Committee of Mr. George Brown, elected Representative on the Medical Council of all the doctors throughout England and Wales, may be taken as evidence.

Another objection raised concerns possible experiments on the lower animals. It is intended, I am told, to constitute a "Ladies' Committee," which, while supervising the numerous future details of a scheme unhappily most pertinent to their sex, will necessarily also preclude even the bare suspicion of cruelty to our less evolved friends and kinsfolk.

As aptly typical of that truly scientific spirit which will, God-willing, dominate the Society's counsels, you will note the name of the Rev. Dr. Dallinger, so famous in the annals of microscopical research.

The reign of our beloved Queen will for ever stand pre-eminent in the world's history for two great points among many lesser.

First: Man's remarkable progress in physical science and increased control over the forces of Nature.

Secondly: His conspicuous "social evolution" in humanity.

We note the closing century on all sides marked by the association of bodies of men for beneficent and humane purposes; and it is a phenomenon of good augury for the ship of state that so keen and discerning an interest in those schemes is evinced by the *Heir-Apparent*. I earnestly hope that the few and fragmentary remarks time permits me now to make will tend to indicate that the present movement is second to few thereof, in sincere intention, in practical beneficence, in width of scope, in fulfilment of public need. That the seed now planted will thrive apace and grow vigorously to a huge tree is hardly open to doubt; and though some of its fruits will appear in our day, those most fully ripened can be witnessed only by future generations. Slightly altering the words of the great fable, "Some men have climbed on those mountains: circle above circle of bare rock they have scaled; and wandering there, have chanced to pick up on the ground one white silver feather dropped from the wing of Truth. And it shall come to pass that when enough of those silver feathers shall have been gathered by the hands of men, and shall have been woven into a cord, and the cord into a net—in that net the Truth shall indeed be captured."

If it be held that the man who makes two blades of grass grow where but one was seen before has

done more to please the Deity than he who says ten thousand prayers, what will be the meed of those who to-day succeed in founding a new Science for vigorous battle with the most agonising scourge of our race? We may not gain the victory, but surely it is our bounden duty to fight for it, and to fight our hardest.

A NOTE ON THE EMPLOYMENT OF EUROPHEN IN RHINOLOGY AND LARYNGOLOGY,

By EUGENE S. YONGE, M.D.,

Hon. Surgeon to the Chorlton-on-Medlock Hospital, Manchester.

EUROPHEN (iso-butyl-ortho-cresyl-iodide) is a substitute for iodoform which may be employed with advantage in all those cases which are suitable for the older remedy. But a salient advantage is its freedom from the peculiar odour of iodoform; moreover, its lightness is such, that a given weight, as compared with iodoform, will cover a surface five times the area of the latter substance. (1) Europhen is apparently non-poisonous, and clings tenaciously to secreting surfaces, liberating iodine—of which it contains 28 per cent.—in the process. I have employed it with success in rhinology and laryngology; and it is in these departments of medical practice that the æsthetic objections to iodoform are most apparent. The faint saffron-like odour of europhen has not been objected to, and its lightness, tenacity, and antiseptic powers render it of very considerable clinical value. The drug has proved satisfactory in minor operations about the nose and throat, and healing has in every case been satisfactorily consummated.

Europhen has acted with specially good effect as an antiseptic and detergent snuff after the removal of nasal polypi. I am not prepared to say, with my present experience of the subject, that in cases of ozæna it is superior to the other drugs in vogue in the treatment of that disease; but Chappel (b) has obtained most encouraging results in such cases. Out of a total of fifteen patients treated, three were cured, whilst the others were much more benefited by this substance than by other remedies.

In a case of hypersecretory rhinitis, under my care, europhen acted more favourably than any other drug or method, and this is in accord with the experience of Petersen. (c)

Case of M. M., æt. 16, female.—Post-nasal adenoids, enlarged tonsils and considerable hypertrophy of the inferior turbinates, which were in a more or less constant state of hyper-secretion. The patient was constantly expelling muco-purulent secretion from the nose and suffered great discomfort on account of the accumulation of this fluid. The adenoids and tonsils were removed, and the inferior turbinal freely incised with the galvano-cautery. As a result of this procedure, some improvement of the nasal respiration accrued, but the hyper-secretion was not diminished. Numerous astringent and antiseptic applications were applied at various times to the intra-nasal mucous membrane, without much success. Europhen, however, rapidly and decidedly diminished the muco-purulent exudation and reduced the amount, within ten days, by about half. The drug was blown into the cleansed nostrils by means of a quill, and applications were made twice daily as long as was necessary. In the treatment of tuberculous ulcerations of the larynx and pharynx europhen proved a valuable substitute for iodoform. Under the influence of regular applications, the loss of tissue assumed the appearance of a healing ulcer and steadily decreased in size.

Case of A. K., æt. 24, male.—Phthisis pulmonalis et laryngeal. Tuberculous ulcer the size of a shilling on posterior wall of pharynx. The ulcer was cleansed twice daily with an alkaline spray, and europhen in powder was then sucked into the pharynx through a

tube. At the end of a week the ulcer was appreciably smaller, had taken on a healthy appearance, and was less painful. Although at the time of the last observation the ulcer had not disappeared, it was still continuing to heal up.

For the local medication of syphilitic ulcerations of the nose europhen appears more effective than such similar preparations as iodoform, iodine-glycerine, &c.

The principal points in favour of the employment of europhen in laryngology and rhinology appears to be (a) its apparent innocuousness, (b) its lightness and tenacity, (c) the absence of disagreeable odour, and (d) its marked antiseptic powers. No by-effects of any kind have ever been noted in any of my cases.

Transactions of Societies.

BRITISH GYNÆCOLOGICAL SOCIETY.

MEETING HELD THURSDAY, JUNE 8TH, 1899.

The President, Dr. MACNAUGHTON-JONES, in the chair.

DECIDUOMA MALIGNUM.

Dr. F. W. N. HAULTAIN (Edinburgh) showed a specimen of this growth, together with microscopic sections, and gave a lantern demonstration of microphotographs, which we hope to publish, with illustrations, in our next.

The PRESIDENT said that the demonstration and excellent illustrations of Dr. Haultain elucidated one of the most vexed questions in gynecology, on which authorities were not yet agreed. The most recent view appeared to be that it must be regarded as a malignant chorio-epithelioma, the typical or atypical nature of which depended upon the character of the chorionic epithelium, and its remaining in its form of early pregnancy, its alliance to other malignant tumours being dependent upon transitional conditions. Personally, he believed in deciduoma malignum as a distinctly malignant tumour, characterised by typical etiological, pathological, and clinical features, and this was the view generally held on the Continent. He had not met with a case in his own practice. The characteristic specimen which he had shown at the Society was one that he had seen removed by Professor Martin, in Berlin.

Dr. EDEN said he thought there was grave doubt whether all the ninety-one cases which had been recorded as cases of deciduoma malignum could bear close examination. The fact was that this new and fascinating pathological theory had aroused the keenest interest in Germany, and there had been some extravagance resulting from the general enthusiasm. This extravagance was evident in a case recorded by Schmore, in which a malignant vaginal tumour was described as deciduoma malignum arising from inoculation of a vaginal wound with placental tissue, no uterine growth whatever being discovered. But there was evidence that opinion in Germany was becoming steadier. In the last volume of Veit's *Handbook on "Gynecology"* the editor expressed his conviction that the chorionic theory was untenable, and that the disease was in reality sarcoma modified by the occurrence of pregnancy. With this view he was personally in full agreement. With regard to Dr. Haultain's case, Dr. Haultain himself admitted that the growth possessed the broad characteristic of a sarcoma. The only structures in it which were peculiar were the large bands and loops of nucleated protoplasm; the other features might occur in any rapidly growing sarcoma. But from the presence of these structures to the theory of deciduoma malignum was too wide a step for the pathological theorist. The relation of the villi to the growth might be equally well explained by the assumption that these were retained, and that the disease subsequently invaded the part of the uterine wall where they were situated. In scientific questions the simplest explanation should always be adopted in preference to the more complex ones, and the chorionic theory of deciduoma malignum formed so novel a departure from established pathological principles that we were justified

(a) "Medical Annual," 1899. (b) Chappel: *Medical Record*, April, 1892. (c) Petersen: *Munch. Med. Woch.*, No. 30, 1891.

in asking for much more conclusive evidence in its favour than had yet been advanced.

Dr. HERBERT SNOW said that the eloquent exposition of Dr. Haultain must not blind them to the complexity of the subject. The question was whether a deciduoma malignum was a quite different kind of thing to any other malignant tumour. They had the broad clinical fact that malignant disease could follow pregnancy, especially in the cervix; but this fact did not require a special nomenclature. Was deciduoma malignum actually more than a name? The fallacies of microscopical examination must be remembered. He could not help thinking that some of Dr. Haultain's explanations of the appearances were a little idealistic. Probably some of the cases described as deciduoma malignum were not malignant at all.

Dr. WILLIAM DUNCAN observed that they had all learned something, and the pains that Dr. Haultain had taken to make the demonstration clear deserved all credit. But he thought that they should deprecate making a special pathology for diseases of the uterus; this had kept gynecology back many times in the past. Thus he had heard of a corroding ulcer of the os uteri, said to be quite different from any other kind of ulcer found in the body; it was really either malignant disease or tuberculosis. All the cases he had seen described appeared to him to be nothing more than sarcoma coming on in a pregnant uterus, and he hoped that the name "deciduoma malignum" would soon disappear.

Dr. HAULTAIN, in reply, thanked the Society for the attention they had given to his demonstration. He knew, of course, that it was a vexed question. The first point to decide was, what was a sarcoma cell? On looking at a single cell they could not say whether it was a sarcoma or an epithelioma. And the difficulty was increased by the fact that the cells from which deciduoma malignum arose were embryonic, and were not found in adult life. He also hoped that the term "deciduoma malignum," which was a bad one, would be given up, but "sarcoma" was even worse, and he should like to see the name "chorio-epithelioma" adopted.

BRADFORD MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD TUESDAY, JUNE 20TH, 1899.

Chairman, Dr. BERRY.

Dr. ENRICH gave a microscopical demonstration of a series of tuberculous tumours, which had been removed under the supposition that they were of a cancerous nature. They were from the penis, scrotum, labium majus, and skin. He also showed specimens:—(1) Secondary carcinoma of heart; (2) the supra renal bodies from two cases of Addison's disease.

Dr. ANGUS brought forward a case of

ERYSIPELATOUS ANTHRAX.

John W., æt. 27, a wool sorter, had been working among Persian wools. On April 28th, he noticed, while at work, an itching pimple on his left shoulder. On the night of May 1st he felt ill, shivered and vomited; the illness continued, and on May 3rd he was seen by Dr. Angus. Condition: Temperature in axilla 100°. pulse 120, weak. On the anterior aspect of the left shoulder was a semi-circular patch, 3 ins. diameter, of blistered and reddened skin, surrounded by subcutaneous ecchymosis. The skin over the front of the chest was reddened and cedematous, while over the right side of the chest and on both sides of the neck and face there was cedema, but no redness. Heart and lungs normal. On May 4th, temperature 99.4 in axilla, and 100.6 in rectum, pulse not perceptible at wrist. The reddened patch increased in size; there was slight cedema of the left arm, left scapular region and the upper part of the abdomen. On May 5th temperature in mouth 97.4, the whole of the front of the abdomen was cedematous, the hands and feet were cold. Patient died at 11 p.m.

Necropsy.—Across the front of the chest and neck the skin was of a dark purple colour, swollen and crepitant on pressure. The subcu-

taneous veins showed a dark purple through the skin. Much clear fluid escaped when the tissues were incised. The retro-sternal cellular tissue was emphysematous. The right pleura contained about half a pint of fluid. The pericardium showed subserous extravasation of blood, and contained 2 ozs. of fluid. The endocardium and endothelium of the aorta were deeply stained. There were patches of extravasation on the peritoneal covering of the intestines. The spleen was soft but not enlarged. Cultivations of the bacillus anthracis were obtained from the pericardial fluid. Photographs of the case were shown.

Dr. RABAGLIATI read notes on a case of

CEDEMATOUS ANTHRAX.

The patient was a man, æt. 47. The illness was only of five days' duration, and the symptoms consisted in swelling of the upper and lower lips, and subsequently of the penis and scrotum. There was no rise of temperature or of the pulse rate. On one day only there was slight shivering. The patient recovered.

Dr. J. H. BELL read notes on a series of cases of "Anthrax," of the cedematous and erysipelatos varieties. He stated that although described as occurring on the Continent, such cases had not been previously described in this country.

France.

[FROM OUR OWN CORRESPONDENT.]

PARIS, July 2nd, 1899.

CONGENITAL PHYMOSIS.

THE operation for congenital phimosis, although of simple and easy execution, can produce certain troublesome consequences as regards the sexual functions in rendering, for instance, erection painful by the traction exercised by the skin of the penis on the circular cicatrix, or by maintaining the glans curved at the moment of erection by the presence of the cicatricial tissue at the seat of the wound resulting from the section of the frænum. In order to avoid these accidents, perfect reunion should be ensured of the skin with the epithelial surface, and the surgeon should operate so that the glans, far from being deprived completely of the foreskin, should be surrounded with a small collar of tegument, so as to permit extension. According to Prof. Pousson, of Bordeaux, this object can be obtained by a combination of means, among which artificial ischemia, obtained by Esmarch's method, plays the most important role as facilitating the apposition of the mucous membrane to the skin at the point of section. After having chloroformed the child, disinfected the parts, and destroyed with the cannula the possible existence of adherences between the mucus of the prepuce and that of the glans, Professor Pousson places at the root of the penis an elastic band, ensuring by this means a bloodless operation. He then introduces two self-acting forceps to within a quarter of an inch of the groove, one in front, the other behind, preventing thus the two layers of the prepuce from gliding one over the other. By drawing on the forceps, the prepuce is brought forward, while the glans is pushed behind, and between the forceps and the glans a fenestrated clamp of Ricord is applied. Immediately behind this instrument 8 or 12 threads are passed and finally the prepuce is cut with a bistoury introduced into the slit of Ricord's clamp. The glans is thus exposed with the sutures lying across it; these are cut in the middle and tied. The operation being terminated, the elastic band is withdrawn, and the hæmorrhage resulting from congestion is

arrested by irrigation with a hot antiseptic solution, while the wound is covered by a paste composed of salol, iodoform, and gum adjuvant. The sutures are removed on the fourth or sixth day.

Professor Pousson says that he never had observed hæmorrhage of any account by this method, and only once or twice did he remark that chronic œdema so frequent at the point of section of the prepuce.

CERVICAL ABSCESS.

M. Hirtz communicated to the meeting of the Société Médicale, the case of a man of 21, mason, without any hereditary antecedents, who received in the month of January violent blows of a stick on the head, but without causing any apparent lesion. However, a few days after he complained of violent pain in the head and vomiting. A month subsequently the patient was seized with paralysis of the right arm, and finally with Jacksonian epilepsy.

In presence of these troubles the trepan was applied over the fissure of Rolando on the left side, and the dura mater incised. The subjacent portion of the brain was found to be particularly prominent, and the needle of a subcutaneous syringe was introduced, giving issue to a drop of greenish pus. It was evident the case was one of sub-cortical abscess, and it was incised accordingly, emptied and drained. The patient made a good recovery, the epileptic attacks disappeared, and the arm recovered its functions at the end of three months.

PRINCESS AND DOCTRESS.

Princes who have acquired, says the *Chronique Médicale*, the title of Doctor of Medicine, are not absolutely rare, but with princesses it is almost unique, and if some of these exalted persons study anatomy and medicine as amateurs, very few assuredly would be capable of writing a memoir like that published by the *Revue Médicale Suisse*, and signed Princess Guédroytz de Béloséroff. This memoir made at the surgical clinic of Prof. Roux, of Lausanne, is very remarkable, it being well documented and profusely illustrated. The choice of the subject, however, seems to us rather singular, as the author, though Princess and a doctress, is a woman. The following is the title of the memoir, "Excision of the seminal vesicle and of the vas deferens in case of castration for primary tuberculosis."

THE CENTENARY OF THE METRIC SYSTEM.

On the "fourth Messidor. an. vii."—otherwise the 22nd of June, 1799—the Corps Legislatif of France adopted and authorised the use of the metric system. The Paris Inspector of Weights and Measures has signalled the occasion by issuing a circular to all pharmacists directing them to adopt the metric system without delay and to cease from using the old measures.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, July 1st, 1899.

At the Society for Innere Medizin Hr. Stadelmann introduced the subject of

SPORADIC OR EPIDEMIC CEREBRO-SPINAL MENINGITIS.

Four kinds of acute meningitis were distinguished:—Meningitis purulenta, meningitis cerebro-spinalis epidemica, meningitis tuberculosa, and meningitis serosa.

All, with the exception of the last, were ætiologically attributable to bacteria, meningitis purulenta, to a number of organisms, the pneumococcus Fraenkel, the typhoid bacillus, the bacillus coli, &c., and lastly to a bacillus discovered by the speaker, which appeared as thick rods. A brewer's drayman had been injured by a case of bottles falling on his head. He was not confined to bed but kept on with his work. Three weeks later he had to give up his work for a day, and sixteen days later he was attacked with violent catarrhal symptoms, rigors, vomiting, headache, twitching of the limbs, backache, fulness about the head, and slowing of the pulse to 56 beats per minute. Four days later he was admitted into hospital. His history was good. There was great irregularity of the pulse, high temperature (39.6 C.), stiffneck, violent headache, no affection of sense, no hyperæsthesias. With the exception of enlargement of the spleen all the internal organs were sound. On lumbar puncture, a very thick, almost purulent fluid was withdrawn under a pressure of 370 mm. It contained albumen and sugar in larger quantities than normal, 55 ccm. were removed. Morphia had to be given as the patient became worse, and for restlessness. Three days later lumbar puncture was again performed, pressure 250 mm., the fluid similar to that previously drawn off, 15 ccm. were removed. No improvement followed, dulness increased followed by delirium, hyperæsthesia of the extremities, irregular breathing, converging strabismus and general twitchings. Food was refused, the evacuations were passed under the patient. Seven days afterwards lumbar puncture was again performed, this time under a pressure of 300 mm., and 15 ccm. of fluid were removed. The condition now improved, the intellect became clearer, but the temperature again rose, and all the symptoms became worse, extreme apathy came on, the breathing became very irregular, cyanosis appeared and nystagmus. Then the condition again improved, this time decidedly. Three days later lumbar puncture was performed for the fourth time under a pressure of 320 mm. The fluid withdrawn was clearer, contained no increased albumen; 5 ccm. were removed. Lasting convalescence now set in with enormous appetite. He increased in weight, and in three weeks was discharged.

On examination of the fluid removed no bacteria were found, and the inoculation tubes were at first sterile. In eight days, however, cultures developed, pure cultivation of thick, very mobile roots, with whips, clubbed ends of polymorphic form not stainable by Gram's method. The cultures on agar presented round, clear colonies, the bacteria were facultatively amœbic. The growth began after three days, grape sugar was not split up. The mobility of the bacilli was very active in the bouillon culture. Milk was not curdled by them. Inoculation experiments on animals and injection into the dural sac gave no indubitable results. Ætiologically the disease was attributable to the bacillus, which was not present in the nasal secretions. The bacterium was new, and hitherto undescribed, its long latency was especially striking. The cause of the happy result, undoubtedly lies in the robust constitution of the patient, and in the possibly slight virulence of the germ. The lumbar puncture did not contribute to the success, it was only of diagnostic importance.

As regarded epidemic cerebro-spinal meningitis, either the meningococcus intracellularis Weichselbaum, or

Fraenkel's pneumococcus could cause it. It was a disease for notification, but a diagnosis could not be made until one or the other micro-organism was discovered. He had not notified his case, as neither of their organisms was present.

Häubner had never found the meningococcus except in epidemic cerebro-spinal meningitis. Occasionally he had found cocci morphologically similar, so that he was inclined to the hypothesis of Stadelmann, that the meningococcus belonged to a large group. Even in diphtheria people had accepted various micro-organism as pathogenic, but later on they had agreed that the offending organism was Loeffler's bacillus. It might be the same with epidemic cerebro-spinal meningitis.

Hr. Kronig had in one case seen pure cultivations of meningococcus cellularis with staphylococcus aureus, the presence of the latter being probably due to furunculosis, from which the patient was suffering. In another case he found the meningococcus, in company with Fraenkel's pneumococcus; he had also found the latter in lumbar puncture fluid in phthisical cases. It was known that this could be injected into the dural sac without causing any mischief. In several cases of suppurative meningitis he had found Fraenkel's pneumococcus twice, and in others the meningococcus. He did not consider even the latter the specific excitor of epidemic cerebro-spinal meningitis, for it could also be caused by the pneumococcus.

Hr. Jacob from his experimental investigations held that there was a certain specific relationship between the meningococcus and the epidemic disease. Other highly virulent cocci could not set it up.

Hr. A. Fraenkel had found the meningococcus in a case where injury had been suffered. It was to be assumed that the bacteria were already present, and that they had wandered into the arachnoidal canal as a result of the trauma. One case of colotyphus presented the clinical features of epidemic cerebro-spinal meningitis, but of course no bacilli (Weichselbaum) were found. He related a third case, actually one of syphilitic meningomyelitis in which on lumbar puncture being made, the pressure was only 2 mm. The cerebral membranes were attached to the foramen magnum so that the communication was closed between the ventricular cavities and the arachnoidal sac—hence the low pressure. The ventricles were dilated to the maximum.

Hr. Krönig remarked that minimal intra-spinal pressure was nothing new. In such cases the upper part was always shut off, and that this was so, could always be concluded, from the pulse oscillations. If these pulse oscillations were absent the communication between the cerebral and spinal cavities was closed.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, June 30th, 1899.

STENOSIS OF THE TRACHEA.

At the Gesellschaft der Aertze, Harmer exhibited a male patient, æt. 24, on whom he had successfully operated for stenosis of the trachea. It appears from the history that this young man had croup when he was five years of age, for which tracheotomy was performed, but for some reason not yet explained the canula was never removed, which gave rise to a large cicatrix so that

at the age of 16 the whole pharynx and vocal cords were involved in a thick, hard belt of fibrous tissue.

According to our plastic dicta two operations are given for the correction of this distortion on the aërial tract—viz., (a) that long wearisome endo-laryngeal process of distending the passage by means of a tube; (b) extra-laryngeal operation by means of re-opening the cicatrix and guiding the union, or what is more recently performed cutting out the cicatrix altogether and so promote union of the healthy edges of the tracheal wall.

Harmer selected a modification of the latter method by making an opening into the larynx in which he left thick threads of silk as drains. Later he applied a Schornstein cannula and dismissed the patient from hospital with it in, and it was removed a few months later. The edges of the wound were finally pared and freshened for reunion, which took place soon after with excellent results. Before the operation the man was unable to converse with his fellow inmates unless by signals or movement of the lips, whereas now he can speak with a loud voice, though a little rough, which may yet improve. With the assistance of the laryngoscope the vocal cords are shown to be quite normal with a good wide larynx.

RONTGEN RAYS AND SKIN AFFECTIONS.

Schiff demonstrated a patient who had suffered from sycosis, chronic eczema, and blepharitis after treatment with the Röntgen rays.

For the sake of contrast, and to prove the virtue of the rays, one side of the patient had only been treated, leaving the other half in its original condition. After ten sittings all the hair had fallen out of the sycosed portion, and the eczematous eruption had immensely improved, while the blepharitis had been quite healed, though the cilia, which had fallen out under the action of the rays, were absent.

TONOMETER.

Gärtner next showed an instrument to the society which he has lately improved for taking more exact records of blood-pressure in morbid states of the body.

In the criticism that followed this demonstration Federn put a few questions concerning its practicability, among which he asked if he could confidently say for the general weal of the profession, that the blood pressure was decidedly reduced in neurasthenia. Gärtner replied by saying that blood pressure *was not lowered* in neurasthenia in the cases he had examined.

CELLULOID IMPLANTATION FOR OSSEOUS DEFECTS.

Weinlechner, in his record of surgical cases, told the Society that celluloid was an excellent substitute for bone, being easily disinfected, free from absorption, and plastic when warm. In cranial openings it was indispensable, and in many cases prevented Jackson's epilepsy, though not in every case, as some would allege. There is another use recently practised in the coaptation of nerves where the plates are furnished with cannulae or small tubules for the reunion of nerves, these are useful in resections.

Weinlechner added that he had practised another use of this celluloid in cases of resecting elbow-joints where it is often desirable and necessary to obtain pseudo-arthritis. In such cases he places a plate of celluloid between the resected bones and prevents their union. He next illustrated his paper by examples. The first was a locksmith, æt. 28, who had received a blow from a hammer on the right temple, causing a large

swelling, which was finally removed and found by microscopic examination to be a tuberculum. Owing to epileptiform attacks after removal, Weinlechner laid the cerebrum bare over a wide area, which he covered with celluloid to prevent union of the dura mater. After eight months the epileptic fits disappeared.

The second case was a similar injury with hernia of the cerebral contents, in which a celluloid plate acted as an osteoplastic barrier.

The third had been a fungoid growth of the elbow-joint, for which he had resected and applied a celluloid plate between the bones to prevent union. The patient could make a wide excursion with the arm with great freedom about the joint.

The fourth and fifth cases were operations for neuralgia of the infra-maxillary and infra-orbital nerves, where resection and avulsion had been tried in vain. A celluloid plate was applied before the ligament in the former, and a celluloid wedge driven into the foramen ovale for the latter.

Continental Health Resorts.

[FROM OUR SPECIAL CORRESPONDENT.]

MONT-DORE (PUY-DE-DÔME, FRANCE).

THE thermal establishment at Mont-Dore (recently reconstructed on the plans of Monsieur Emile Camut) belongs to the department of Puy-de-Dôme. It contains very complete hydrotherapeutic appliances, of the most modern and approved character, and very systematically arranged. The two separate buildings are connected by a bridge, and two handsome staircases lead to the upper floor. The building is set apart for treatment by vapour, containing rooms for inhalations and pulverisations. The other building contains the springs and baths, and has been re-arranged in recent years at a cost of £120,000. It has numerous galleries for baths, douches, inhalations, pulverisations, nasal-douches, foot-baths, and hydro-pathic treatment generally. In the upper story is a large central hall, with a roof supported by eight fine columns of polished Vosges granite, each column twenty-seven feet in height, and cut from a single block. The galleries are artistically decorated with antique statues, pillars, votive-tablets, and other objects rescued from the Gallo-Roman ruins. The establishment itself is erected at *l'Angle*, at the foot of a mountain, on the spot where the Celtic and Roman remains were situated; and it is over the springs themselves, so that the waters lose neither their heat nor efficacy by distance.

The waters are administered in four principal methods: drinking, inhalations, douches, and baths. They are drunk in various doses of half a glass to four glasses daily, and are most effectual taken in the mornings, fasting. Almost invariably they create appetite; sometimes causing diarrhoea, and occasionally constipation. The kidney secretion is almost always speedily increased, and the secretions from the mucous membrane of the larynx and trachea sensibly modified. The aspiration of the vapours of the Mont-Dore mineral waters is a mode of application growing in favour among the local physicians, especially in cases where the invalids are too weak for bathing or drinking. Patients remain in rooms filled by steam (produced by peculiar engines) and heated from 82 degs. to 89 degs. Fahrenheit for

twenty minutes to one hour, as prescribed in each individual case. (The air of these vapour-rooms is renewed by powerful ventilators, and thus perfectly purified. Vapour thus introduced is found to soothe the irritation of the respiratory mucous membrane, and to reduce congestion of the lungs; preparing the way for other and special treatment for asthma, bronchitis, and phthisis. It is also found a preventive of hæmoptysis, which sometimes succeeds a course of sulphurous waters.

The inhalation of the vapours of the Mont-Dore waters, and of the waters pulverised into fine sprays have a very sedative effect upon the mucuous membranes, and a most remarkable effect upon granular sore throats. The douches are given in jets and showers, local or general, and produce especially a stimulation of the circulatory system. Nasal douches and irrigations of ten or twelve minutes' duration are found useful in diseases of the nose, chronic coryza, ozæna, ulcerations, &c. Vapour douches are employed for chronic catarrhs, sciatic and intercostal troubles, rheumatism, and wherever it is desirable to produce revulsive action of the skin. Garglings with the mineral waters at various temperatures are prescribed for affections of the throat, pharyngitis, and laryngitis.

A peculiar feature of the Mont-Dore establishment is the special hot baths in the *Parillon*, built immediately over the actual springs. They are taken as half and one-third baths, the water running through them varying from 108 degs. to 109 degs. Fah. These baths are the most active of all the treatments given at Mont-Dore, speedily producing marked effects. The bather's skin becomes red, his pulse gains greatly in rapidity and strength, his respiration quickens, and he perspires most freely. In ten minutes his skin moistens and softens notably to the touch, and his breathing equally increases. Dr. Bertrand attached much importance to the diaphoretic action of the *Pavillon* baths. To the looker-on the foot-baths are, however, the most amusing part of Mont-Dore treatment, as mentioned in a former letter, in my "Notes on an August Holiday in Old Auvergne," it is one of the unique sensations of the district.

The establishment is open from June 1st to September 30th. The treatment customarily continues from fifteen to twenty-one days, and the most favourable times are considered to be the *second* fortnight in June, and the *first* fortnight of August. When the atmosphere is *heavy* and strongly *electrical*, the excitability of the patients may increase, attended with sleeplessness and gastric derangements; in these instances the treatment is suspended for some days, otherwise it continues daily and consecutively. The regimen varies according to the peculiarities of each case; stimulating food, rich sauces, and spiced meats are forbidden; otherwise (except in special instances) no fixed rules of diet are observed.

The "cure" at Mont-Dore operates as a tonic generally. Usually it is strongly sedative; the pulse quietening; sleep becoming more regular, and congestions ceasing. Appetite increases, digestion improves, bacilli disappear, the skin recovers its normal nature, and there is a general recovery of strength and health.

But, naturally, the age, sex, temperament, constitution, hereditary symptoms, and other incidents of each patient must ever be considered. These indicate the proper method of administering and applying the waters, and upon this method depends much, for the waters,

according to the care and the mode of application, may increase instead of lessening congestions, and may become exciting instead of sedative. It cannot be too frequently impressed upon invalids seeking relief at Continental Health Stations that to obtain the desired results able and locally-experienced medical advice and supervision are intrinsically important, for the different waters affect different people in different ways. Hence the necessity of an experienced physician's guidance during the "cure." At Mont-Dore are a number of such physicians, speaking various languages. The English resident physician, Dr. E. Emond, who is well known in London, is a member of several English, French, and Spanish medical societies, and has had many years successful practice at Mont-Dore.

The Operating Theatres.

WESTMINSTER HOSPITAL.

ACUTE MASTOID ABSCESS. PERFORATION IN THE POSTERIOR PORTION OF THE MASTOID (BEZOLD'S).—MR. DE SANTI operated on a man, æt. about 47, who had been admitted under him with acute mastoid abscess. The history was that the patient had had an attack of facial erysipelas, after which he had profuse fetid discharge from the ear; this was followed by the formation of a large deep-seated cervical abscess extending from the mastoid process to the level of the thyroid cartilage. There was a large sloughing mass in the external auditory meatus. The patient had a high temperature and looked very ill. After the administration of an anæsthetic an incision was made over the mastoid extending right down to the abscess, which was found to be underneath the deep cervical fascia, and from which a large quantity of pus was let out. The mastoid antrum was opened in the usual way and the pus evacuated from it. On careful examination perforation of the mastoid bone was found in its deep or posterior aspect, and this perforation communicated with the abscess cavity in the neck (Bezold's perforation). The whole of the parts were then thoroughly dried and drained. Mr. de Santi said that Bezold's perforation was an uncommon condition to find, but he considered that it was most important for the surgeon to bear in mind that such a complication might occur, for unless the mastoid bone itself were operated on in such cases, the deep seated cervical abscess which resulted from the perforation would not heal.

The patient did very well till three weeks later, when he got a sudden attack of cutaneous erysipelas on the other side of the face; this caused serious constitutional symptoms, and profuse suppuration from the old abscess cavity. The case was treated with antistreptococcic serum by the house physician, Dr. Bond, and the patient made an excellent recovery.

GREAT NORTHERN HOSPITAL.

RUPTURED TUBAL PREGNANCY.—MR. PEYTON BEALE operated on a woman, æt. about 30, who had been admitted with the following history: She had been quite well until three days previously, the last menstrual period having been completed about one week before. On lifting a chair she stated that she felt something give way in her right side. This was followed by a sharp pain, which passed off in the course of a few hours. She was seen by a medical man on the following day, and was

then becoming rather collapsed, the abdomen getting distended, and the pulse feeble and quick. On the next day she was sent to the hospital, when her condition was as follows: Abdomen enormously distended, tympanitic in front, quite dull in both flanks, face and skin very pale, pulse hardly perceptible and very rapid, gasping respiration, and she appeared as if dying. The abdomen was immediately opened in the middle line, and was found quite full of very dark blood clot; this was rapidly pulled away, and the abdomen repeatedly flushed out with hot sterile water; it was then seen that there was a small rent in the right Fallopian tube, which last, however, was not larger than normal. The tube was rapidly ligatured on each side of the rent, and the intervening portion removed. The abdominal wound was closed in the usual manner, a small aperture being left above, through which a glass funnel was inserted and hot salt solution was poured in, the air being allowed to escape by the side of the funnel. Salt solution was poured in until the abdomen was as distended as it was prior to operation; stitches were then inserted on each side of the funnel, so that when it was withdrawn very little fluid escaped. The whole operation only lasted ten minutes, and no anæsthetic was administered after the primary skin incision. Mr. Beale said the case was of interest: First, on account of the very slight injury which had apparently caused the rupture of the tube, it was difficult, he thought, to believe that pregnancy could only have been of one week's duration, but in cases of tubal pregnancy menstruation commonly persists. Secondly: On account of the large amount of saline solution which was injected and which it might be said was absorbed within one hour, so that one hour after operation the patient had full pulse. There seems, he remarked, to be no reason why the quantity of saline solution injected should not equal the quantity of blood effused, and he stated that he would be prepared in a similar case to inject still more by forcing a funnel between two of the stitches if necessary after the first lot had been absorbed; indeed, he considered that in cases of hæmorrhage from any part of the body, hot saline solution should be forced into the peritoneal cavity, as it could be so rapidly done through a cannula and was so quickly absorbed. The ovary was not removed, he said, because it would have involved the application of more than one ligature, and time was of the greatest importance if the patient's life were to be saved, and he thought that in such a case nothing but that which was absolutely necessary at the time should be attempted.

The woman made an uninterrupted recovery.

A New "Food" Hospital.

At the ordinary general meeting, held last week, of the shareholders of "Mellin's Food Company, Limited," the chairman took occasion to remark that Mr. Mellin had established a new children's hospital, in which the inmates would be reared on the food bearing his name, which "he believed would have a great effect on the medical profession." By this admission the public would naturally conclude that the medical profession was against Mellin's Food for infants, and that it needed the practical demonstration of a new hospital to convince it of its unwisdom. If this is the opinion held by the chairman, we would like to point out to him his mistake, the profession as a whole has always considered "Mellin's" to be an admirable food for infants, prepared on a sound and scientific basis.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JULY 5, 1899.

COVENTRY AND ITS MEDICAL CLUBS.

FOR some years past the so-called "Battle of the Clubs" has been actively waged in the busy manufacturing town of Coventry. So far back as 1892 it was publicly stated by the chairman of the Provident Dispensary of the town that out of a population of 52, no less than 25,000 or 26,000 belonged to the organisation in question. Since that date we understand that no returns have been published, but it may be safely assumed that any change in numbers will have been in the direction of increase in an institution that admits all comers without question of income. Within the last few days we have been informed upon what we believe to be good authority that persons whose income amounts in some cases to a thousand a year are, nevertheless, on the books of the Provident Dispensary, and thus secure for themselves medical attendance and medicine at the paltry and miserable pittance of one penny per week. Upon such evidence as this, if established, any system would stand self-condemned. Unfortunately, there is no need to hesitate in accepting the statement as to the membership of unfit persons, because the published facts of the case bear out the charge in every particular. In July, 1897, for instance, the report of the Ethical Committee of the Birmingham and Midland Counties' Branch of the British Medical Association appeared in the official organ of the Association. After a full and exhaustive inquiry it showed that the medical staff received a sum varying from 1s. 1d. to 1s. 4d. per head out of the annual payment of 4s. 4d. by each member; that the staff was wholly under the control of a lay committee, and were not permitted to consult with any medical man outside their own ranks; that canvassing for members was carried on, and that the medical profession was

exploited by the dispensary with a view of making a pecuniary gain out of their services. In September, 1897, the Provident Committee rejected with one exception the specific request of the medical staff for the following additions and alterations to existing rules:—(1) a wage limit; (2) the cancelling of the rule requiring the appointment of a new Medical Officer when the aggregate salaries of the staff should equal an average of £350 respectively; (3) all the members of the staff to sit on the committee instead of only two; and (4) children's subscriptions to be raised. The fourth recommendation was the only one adopted in its entirety, but the sum mentioned in the second clause was raised from £350 to £400. In commenting upon these proceedings the members of the staff were pointedly advised by all the leading medical journals to resign their appointments. Last summer, at Edinburgh, a further important stage of the affair was notified in the following announcement:—"That after a prolonged and careful inquiry, the Council of the British Medical Association is of opinion that the members of the Coventry Provident Dispensary staff are continuing a system of medical relief which is incompatible with the best interests of the profession, and hurtful to their professional brethren practising in the neighbourhood." Since that time the Council of the British Medical Association have remained silent upon the subject. As readers know, the whole question of the Medical Aid Associations was brought before the General Medical Council a few weeks ago, and has been postponed for future discussion. Meanwhile, another annual meeting of the British Medical Association is at hand, and it is to be hoped that the Coventry Question will be brought once again into prominence. After having laid their hands to the plough the Council of the Association can hardly refuse if called upon formally to take further action. The staff of the Coventry Dispensary have been treated with the utmost patience and leniency, but surely the time has now arrived for sharp and decisive action. The case of Coventry is the case of the country at large. Let the medical profession at Portsmouth raise such a discussion as shall settle once and for all the attitude of the main mass of practitioners with regard to the "sweating" and advertising tactics adopted by the friendly and other societies that include medical relief in their scheme of operations. One point should be kept carefully in mind—namely, the value of a strong and united expression of opinion at this juncture in influencing the future action of the General Medical Council. It is to be hoped that the medical men of Coventry, or better still, the Midland Counties branch of the Association will prepare a further pointed and concise memorandum of the facts of the case for the benefit and behoof of the Portsmouth meeting.

THE DIETETIC VALUE OF DRIED FOODS.

AN interesting feature of recent industrial progress in dietetics is the revival of dried foods as a

factor in provisioning. Of course the earliest form of food preserving consisted in the simple process of sun-drying; and later on artificial heat, combined with the more or less efficiently antiseptic smoking, came into force. But drying, as applied to preserving foods, has its limitations, and was not altogether satisfactory, for in the process something more than the mere superabundance of moisture was lost. This was peculiarly true as regards vegetables and fruits. However, systematic experimentation, chiefly in America, then in Australia, and quite recently in England, has resulted in great improvements. We now have sliced dehydrated fruits—such as apples, pears, and apricots—which in a dry form can be closely packed, will last long, and on being soaked in water regain their natural physical characters, as well as their original flavours. This perfection is attained by the careful selection of fruit, and judicious drying in closed but ventilated appliances. What has been done with fruit is now being done with vegetables. At the present time vegetable garden produce is being preserved in England mostly by the simple process of dehydration. This has been carried so far and so successfully that even beetroot in thin slices can be dried hard, yet retaining all its characteristics, including colour, and when these slices are soaked in pale malt vinegar, they swell, become tender, and impart a bright red tint to the liquor. Onions, potatoes, turnips, carrots, asparagus, seakale, and even lettuce can be treated in the same manner. It is to be noted that the process is merely one of systematised preparation and drying, no chemicals are used, and yet flavour and colour are absolutely retained. It is clear enough that this improved system of drying has many advantages over some other methods of preserving foods. There is reduction of bulk, lessening of, and when properly packed, complete safeguard against the dangers of fermentation, and the exclusion of all added chemical antiseptics, which, as commonly used with fresh or bottle fruits, must have a more or less decided influence on digestion. Moreover, these dried vegetables and fruits can be quickly prepared for consumption, and can be kept for travelling, or for storage against seasons of scarcity, with far greater ease and sense of security than edibles put up in glass or tin. In more than one direction, this improvement in desiccation has been applied to flesh foods with some amount of success. Indeed, as regards the drying of eggs, the process proves of the highest excellence and utility. The dried eggs, in powder or small oval pellets, have merely to be soaked in a little water, when they can be beaten up and used for every description of culinary work with absolutely satisfactory results. Considering the reliance that one must place in eggs in invalid dietaries, and the unreliability of their supply under various circumstances, this victory of the manufacturers is a veritable boon. A welcome feature in this new phase of food preserving, is that the provisions are generally of home growth and British manufacture, and will

thus prove a help to the farmer as well as to the consumer. It is unnecessary to dilate upon the advantages attaching to dried goods in the matter of storage, say on board ship, for travellers for victualling armies in the field, or for stocking storerooms in order to have a reserve against sudden demands on the commissariat or unexpected dearth in the markets. But what must be emphasised is the fact, that by the scientific application of artificial heat, the vegetables and fruits are deprived solely of their moisture, and thus they retain all their nourishing and health-giving qualities, in fact, merely require to be given the chance of re-absorption of water to become fresh vegetables and fruits once more. This new tendency in the food market is full of interest, and deserves to be noted by our readers, as its practical bearing may sooner or later become apparent to them. In conclusion, just a few practical hints. These dried fruits, vegetables, and meats should be soaked in water for fifteen or twenty minutes before attempting to cook them, and if they are to be boiled, heat gradually. When fruit is in question, stew until soft, and do not add sugar until the last moment. Sugar added too soon is apt to harden the fruit and to caramelize rapidly. Onions and potatoes, when once thoroughly soaked, may be placed to drain in a sieve, and then be dried in a cloth, when they will be quite ready for frying.

COMPARATIVE MEDICINE.

THE anti-vivisectionists are very fond of quoting opinions to the effect that experiments on the lower animals afford no safe guide to the treatment of disease in human beings. Taken literally, no doubt there is some truth in the assertion, but if we take a broader view of the subject it will be seen at once that there is no such thing as human disease, any more than there can be any purely human physiology or anatomy. Human anatomy is but one small department of ethnology, and he who has limited his studies solely to the dissection of human beings cannot be said to have attained any real grasp of scientific anatomy. It has only been by prolonged observation of the body functions in animals that we have slowly built up the present science of physiology as applied to man. Comparative anatomy is now generally recognised as a department of study indispensable to the proper comprehension of anatomy as a whole; but we are now invited to go a step further, and to formulate a scheme for the study of comparative medicine. The more we learn of the etiology of disease the more we are fain to recognise the intimate connection that exists between disease in man and in animals. Animals, indeed, are responsible for a large share in the dissemination of many of the diseases from which human beings suffer. To study diseases such as malaria, diphtheria, and tuberculosis exclusively from a human point of view, is to court failure, inasmuch as the general principles underlying the propagation of such diseases must necessarily escape observation.

We are gradually getting to understand that the comparatively brief time allotted to the studies which qualify for medical practice might more advantageously be devoted to learning to grasp principles, for the details can only be learned in actual practice. The study of comparative medicine, however, is of a kind which pre-supposes a certain and not inconsiderable standard of knowledge of disease as it presents itself in human beings so that it will have to be of the nature of post-graduate work. Harvard University is, we believe, the first educational body to give expression to these ideas, and a chair of comparative medicine has been founded for the express purpose of providing facilities for its study and for the original research which such study implies. The departments under the new organisation will be medical, veterinary, dental, and post-graduate. It is hardly necessary to point to the immense benefits likely to accrue to the community from the study on a large scale of the therapeutical and prophylactic problems of the day in properly equipped laboratories and hospitals designed for experimental research on the lower animals and the study of their diseases. It is hoped in this way to co-ordinate the observations which are being carried on in special departments, and while specialism in study is just as essential to thoroughness of work as specialism in medicine is to dexterity in treatment, it is felt to be desirable and possible to break down the barriers which at present separate investigators in the various departments and tend to minimise the value of their observations by narrowing their respective horizons.

Notes on Current Topics.

A Medico-Legal Problem.

A SOMEWHAT remarkable case was tried at the Winchester Assizes last week, which opened up several knotty questions in criminal psychology. A young soldier was charged with having fired upon the sentries sent to relieve him. He discharged in all four shots, inflicting serious injury upon one of the men. There was no suspicion of personal motives, seeing that he did not even know the injured soldier. It seems that the accused, who was only eighteen years of age, was doing sentry duty on a bright moonlight night, and he appears to have been greatly disturbed by certain ghost stories that were current relating to apparitions believed to haunt the barrack quarters where he was stationed. The prisoner, however, declared that he had no recollection whatever of the affair, though immediately after his arrest he admitted that he knew he was firing at the relief party though he was unable to explain why he did so. It appeared that the prisoner's rifle ought not to have been loaded according to the rules, and no explanation was forthcoming as to how and when it was loaded. The whole story, as given in the reports, is strongly suggestive of auto-suggestion, a psychical condition which is extremely probable in a nervous lad under these circumstances. The absence of motive, and his evi-

dently confused mental condition when arrested, point to some abnormal mental perturbation which gives support to his statement of inability to recall the events. Unfortunately we are not placed in possession of any details of the prisoner's family history, which, might possibly have thrown considerable light on inherited tendencies. It is a relief to find that in view of his good character, though found guilty, he was discharged on his own recognisances, as otherwise we should have experienced grave doubts whether grave injustice had not been done. Similar occurrences have often been reported in persons subject to *petit mal*, but in the absence of any positive information on this point, it is unnecessary to speculate on the plausibility of the diagnosis in this instance.

Conscientious Objectors at Oldham.

MR. CHAPLIN can hardly point to Oldham as a local proof of his assertion that the actual number of vaccinations has increased under the new Vaccination Act. In the course of the Parliamentary election contest now going on in that town the question of vaccination has come into prominence. It was publicly claimed by an anti-vaccinationist that his party comprised 97½ per cent. of the total population. It was further stated that no less than forty thousand certificates of exemption have been granted to "conscientious objectors" by the local magistrates. The Unionist candidates are reported to have expressed themselves as "stern believers in vaccination." The Radical candidates, on the other hand, declared against compulsion. Under such circumstances the ultimate destination of votes may be pretty safely surmised should the compulsoriness of vaccination be made a test question. Most medical men will agree that the vaccination laws should not be made a party matter, but the die has now been conclusively cast. If Mr. Balfour and his friends expected to gain any lasting support from the anti-vaccinationists he is likely one day to fall on a bitter awakening. In the keen fighting of an electoral campaign who can wonder if the Liberals adopt the non-compulsory attitude which has been passed into law by their opponents. Any Conservative candidate who advances at this late hour of the day his conscientious admiration for compulsory vaccination should ponder well and duly Mr. Balfour's great legislative achievement in the contrary direction.

Diabetes Among Native Indians.

THE educated Bengalee has lately been proved to be a great sufferer from diabetes, and the causes of the malady have been attributed to excessive brain work, malnutrition, and early marriages. It is pointed out in a native paper that there are hundreds of cases of the disease at the present time. Moreover, many well-known Bengalees have thus fallen victims to early marriages and university education. We learn that the remedy lies in the hands of the leaders of the Bengalee Society and the

Government which is mainly responsible for the system of education that prevails. Quoting from our authority it is stated "Hindu parents who are anxious that their sons should enjoy health and long life should not think of marrying them before they attain at least their twenty-fifth year, and the Government should see that the subject of study and number of text-books for the various examinations are fixed, with the precaution that they may not overburden the minds of the examiners (*sic*) and that greater attention is paid to physical education in the schools than at present." It is a great deal, no doubt, to have discovered, as in this instance, the cause of the diabetes, and the advice tendered for dealing with it is excellent. The examiners, no doubt, will appreciate the delicate reference to themselves. Of course the examiners should be properly looked after, otherwise diabetic coma might become a frequent occurrence among them while discharging their duties in the class rooms. If, however, diabetes is largely prevalent in Bengal, as here stated, possibly the matter will attract the notice of the officers of the Indian Medical Service stationed in the province, and in that case it would be interesting to learn from them what in their opinion is the cause of its prevalence.

The Plague in Egypt.

At the end of last week the total number of cases of plague reported at Alexandria reached the total of forty-seven, of which eighteen have ended fatally. Ten of the new cases occurred within the last seven days. The fact that no cases have occurred elsewhere in Egypt is to some extent satisfactory. At the same time it would be idle to attempt to overlook the extreme gravity of the present situation. The invasion of plague of a country where general sanitation is in so backward a state as that of Egypt must always be a serious matter, nor does the occurrence of one fourth of the cases within the last week tend to reassurance; on the contrary, it clearly points to a local increase in the disease. Unless the outbreak can be kept within a ring fence, and stamped out before the autumn at Alexandria, there is every prospect of a rapid and disastrous invasion of many towns along the Mediterranean littoral. Happily, in these modern days of high standard sanitation in Great Britain, there is little chance of this scourge of mankind ever gaining anything more than a detached and precarious foothold in our seaports. Indeed, one need not fear the plague nowadays any more than cholera. Filth diseases need a filth environment for their successful fostering. However, it must be admitted that it is so far satisfactory that the plague in Egypt is confined to Alexandria. According to the correspondent of the *Times*, the disease is attacking the lower classes in the native quarters only. The measures adopted—namely, isolation of the sick, segregation of those who have been in contact with them, and the disinfection of their houses and effects—are keeping the disease well under control. The enforcement of

these precautions, moreover, it is of interest to note, is not resented by the population, a fact which goes to show that the natives are beginning to see the wisdom of the action of the sanitary authorities.

Hot-air Baths for Workhouses.

CONTINUITY of policy is a desirable thing in most administrations, whether they be great and central or small and local. An ideal of that kind, however, is rarely attainable amidst the turmoil of our modern social machinery in motion, and the wheel that moves in one direction to-day may drive in exactly the reverse way to-morrow. An apt illustration of this see-saw tendency was afforded a week or two since by the Cheltenham Board of Guardians. It seems that the late Medical Officer of the workhouse and his deputy were so struck by the merits of a certain hot-air apparatus that they forthwith induced the guardians to make an installation. Then came a Medical Officer who knew not Joseph, and he has sent in a recommendation to discontinue this special treatment. Now, there are weighty reasons for caution in abandoning any therapeutic measure that offers relief to these scourges of the poor, chronic rheumatism and rheumatic gout. As everyone who is familiar with Poor-law administration knows, those two conditions cripple a large proportion of the paupers who drift into the workhouse infirmaries with no prospect of ever leaving them again. The treatment of the disabled joints in those above-mentioned conditions seemed hopeless until the local hot-air bath appeared upon the scene. The progressive step of the Cheltenham Board, therefore, in providing the necessary apparatus for carrying out the new treatment deserved the highest consideration. Alas! that they have so soon fallen from grace! A short sum of the total loss to the nation yearly by reason of rheumatoid arthritis would be a revelation to statisticians. Will not some enterprising Board of Guardians apply the method systematically if necessary under special skilled medical supervision, and publish a statement of results?

A Public Unsympathetic towards Idiots.

The position of the class of unfortunate persons for whom such institutions as the Royal Albert Asylum provide accommodation, is one which excludes them from that human aid and sympathy which they so much deserve, owing to their unhappy condition; and, as the chairman of the meeting held in the Town Hall, Liverpool, a few days ago observed, of all philanthropic movements, this is one which should most strongly appeal to the public. Unfortunately, the public develops its social instincts and sympathies in fashionable channels, and the rather appalling appearance and manners of some of the unfortunate inmates of institutions for idiots, shut themselves and their fellow afflicted inmates out from the knowledge, interest, and sympathy of the outside world. And just because such institutions are, therefore, not so much in the public eye, they do not receive the practical help deserved. All this,

notwithstanding, there are men like Sir J. T. Hibbert who rise to the occasion, and recognise that the work done for an institution of this character may be described as thrice blessed, for it confers a blessing on the patients, on their families and their homes, and on the nation at large. The Royal Albert Asylum has done good work in the past, it is still doing splendid work, and the friends of the institution support it by their energies and their means in a manner which is creditable to their Christian charity.

The Royal College of Surgeons, England, and its Members.

THE Supplementary Charter which is shortly to be applied for by the Council of the Royal College of Surgeons to enable them to confer the honorary Fellowship upon persons of distinction who are not members of the College, will doubtless be fully discussed at the meeting of the "Body Corporate" at the College this afternoon (Wednesday). The occasion will be made use of by the Society of Members to represent to the Council that the opportunity would be an exceedingly favourable one for obtaining for the members a share in the government of the College. By incorporating this concession in the Supplementary Charter, it is pointed out that the Council would settle a long-standing controversy, which, especially during the past fifteen years, has occupied a prominent position in College politics. The Society lay stress on the fact that at least one ex-president, many Fellows, and some 5,000 members have expressed agreement with the suggestion that the members of the College should be directly represented upon the Council. But while every effort may be made to extract this reform from the Council, there is very little reason for supposing that it will be granted. The adamant position which the Council have hitherto assumed regarding this question is not likely to undergo any change even under the altered circumstances of making an application for a Supplementary Charter. The object, moreover, of the Charter is not one which the members could honestly oppose, and, therefore, even if it were opposed, no risk would be incurred to its application. Under the circumstances, then, we cannot admit that the Society of Members have chosen a favourable opportunity for bringing their claims before the Council, for the Council have nothing to lose by their refusal to consider them. The case, however, would have been vastly different if it had been intended to apply for a charter embodying controversial matters. The members would then be in a position to seriously imperil its prospects by actively opposing it unless and until their demands had been incorporated in the document. But, in any case, the possibility is that the proposal to admit members of the College to the Council would meet with a great deal of opposition from the majority of the Fellows, and, clearly, if the Society of Members are seriously desirous of bringing about this reform, they should first of all endeavour to win the Fellows to their side.

The Resuscitation of the Royal London Ophthalmic Hospital.

IT is somewhat remarkable that for so many long years the largest and most renowned ophthalmic *clinique* in the world should have been so poorly "housed," as has been the case with the Royal London Ophthalmic Hospital in Moorfields. However, we are glad to record that something has at last been done to remove this stigma from a rich and influential community. Last week their Royal Highnesses the Duke and Duchess of York opened the new building of this hospital in the City Road, which consists of three blocks—the whole of the ground floor being taken up with the out-patient department. The wards afford accommodation for fifty in-patients, and throughout everything has been designed upon a scale in accordance with modern requirements. The Chairman, in referring to the work of the hospital at the opening ceremony stated that the charity was founded as long ago as the year 1804, and that the average daily attendance during last year was 416, on each working day. Regarding finance it is interesting to note that the old hospital building was sold for £78,000, while the new structure has cost £80,000. These sums so far as they nearly balance, seem to be satisfactory, but there is an important difference financially between the old and the new hospital. In the former case the building was on freehold land, while in the latter a ground rent of £1,210 will have to be paid every year for the 99 years during which the lease has been granted to the hospital. It is, therefore, proposed to raise a sum of £50,000, and so invest it that the interest arising therefrom will provide for the ground rent. The Duke of York made a gracious speech in declaring the new building open, and congratulated all those concerned upon their successful effort in bringing the building scheme to such a satisfactory conclusion.

The Progress of Cremation.

THE last report of the Cremation Society of England shows steady progress in this method of disposing of the dead. In 1898 there were 173 persons cremated at the Woking Crematorium, whereas in 1885—the first year in which the Society commenced operations there were only three, and in the next year ten. A point worthy of note is that the cremations so far have been mainly carried out upon the instructions of the richer classes, despite the fact that the charges are by no means prohibitive. This result would seem to imply that the less-favoured classes are still struggling with the sentiment that cremation is opposed to the ordinary procedures of burial which obtain in this country. It is probably quite true that cremation is still regarded by the majority of the community as too unconventional, and, therefore, undesirable. But it is also quite possible that in the course of time this feeling will become less and less pronounced, and that the public will come to recognise in cremation a desirable, economical, and scientific method of the disposal of the dead to which it is expedient to

resort. Sentiment, of course, is a powerful incentive to the retention of the time-honoured earth-burial system with its many old associated customs and, we might add, extravagances. But, despite all this, we believe that the day of cremation will come—long before the world is itself destroyed by fire in accordance with prophecy—and that the sanitary needs of the population will render this method necessary.

Constipation in Children.

CONSTIPATION in infants is the practitioner's bug-bear. He recognises the unadvisability of the habitual administration of laxative drugs to the young, but is often driven to countenance their use by the paucity of the resources of which he disposes. It is important to bear in mind that constipation in infants is due in large measure to the element casein which, if it be present in milk in larger proportion than normal, as compared with the fatty elements, tends to interfere with the due performance of the digestive functions. A child fed on normal casein, but with a low proportion of fat, will probably be constipated. In breast-fed children it does not follow that the proportions of casein and fat are normal, for the maternal supply may be faulty in this respect. Disturbances of health, especially in the direction of indigestion, on the part of the mother, will necessarily be reflected in the composition of the lacteal secretion, as can be demonstrated by analysis. The first step, therefore, must evidently be to regulate the habits and life of the mother. She must be placed on a fresh meat, fresh vegetable, and fresh cooked fruit diet with due provision for regular exercise and restriction in the matter of tea drinking and other dietetic irregularities. This *régime* will diminish the proteid and increase the fatty constituents of the milk, and will go far to rid the infant of the tendency to constipation. Should it fail the best treatment for the child is the administration of cream in doses of from one to two teaspoonfuls in warm water from time to time just before the periodical meal. Failing trustworthy cream, half a teaspoonful of cod liver oil is a good substitute. In bottle-fed children the treatment of constipation is much simpler, for we have only to secure a due proportion of fat and proteid. It may be necessary in some cases to reduce the ingestion of proteid by giving cream, water, and sugar mixture *vice* one or more of the ordinary meals of prepared milk. Dr. Kerley suggests a mixture of four ounces of cream with twelve ounces of milk, which will give four per cent. of fat with a minimum of proteid. In older children the same care to secure a due proportion of fat in their dietary is equally imperative, for much of the constipation from which such children suffer is primarily due to a deficiency of fat. This is a point which ought to be attended to from the earliest period because, if allowed to continue, we get what may be called "fat dyspepsia." The administration of fat then becomes difficult, but the obstacle can usually be got over by a little perseverance. It is surprising how many persons at all ages declare themselves unable to digest fat. This is in many

instances due merely to the formation of a habit; the stomach has been allowed to become unaccustomed to the digestion of fats, and until the tendency has been overcome the mere sight of fats excites repulsion.

Medical Practice in a Free Country.

AN inquest held last week in London is worthy of a passing note. An East-End Jewess, rejoicing in the euphonious name of Lipshitz, called in the services of a "Dr. Barnato, of Russia," to attend her sick child. At the ensuing inquest medical evidence was tendered to the effect that the physic given to deceased by this Russian immigrant was not suitable to the case, although, on the other hand, it did not hasten the unfavourable termination of the illness. Witness claimed that he was qualified to practice in his own country. One of the jurors observed: "This is a free country, and I think every one has a right to act here and get a living." That is the precise view of a great proportion of the inhabitants of Great Britain, with regard to unqualified and qualified medical practice. They imagine that it is a mere question of liberty of action, forgetting there are many things in which the Government has to step in and protect the subjects of the realm. The sale of liquor, for instance, demands strict supervision. The practice of the legal profession is hedged in with iron-bound regulations, and although a similar remark is not applicable to the practice of medicine and surgery, there is no conceivable argument that could be advanced in favour of state regulated legal practice that does not apply with equal force to medical practice.

The Premier as a Chemist.

It is stated that Lord Salisbury has discovered and completed an important chemical process in his private laboratory at Hatfield, and that the results will be made known to the world on his behalf at a forthcoming meeting of one of the learned Societies. The scientific world has for long known that it had in the English Premier a devoted student to chemical science. Despite the arduous duties attached to his official post, he, nevertheless, snatches every available opportunity of prosecuting his favourite study. No doubt scientific researches provide for Lord Salisbury that solace and recreation without which it would be impossible for him to conduct the affairs of this nation with the strength and ability which he has shown. However, it is expected of an English Premier that he prove himself a man of parts, apart from his high official position, and it may be said of Lord Salisbury that he is the first of his class who can lay claim to the reputation of a scientist.

THE RT. HON. VISCOUNT KNUTSFORD and Lady Knutsford will distribute the prizes to the students and nursing probationers of the London Hospital Medical College in the Library, on July 18th, at 4.15 p.m.

The Leavesden Poisoning Case.

SENTENCE of death has been pronounced on the unfortunate girl who has been found guilty of the charge of having poisoned her sister, an inmate of Leavesden Asylum, by means of a cake forwarded anonymously by post. The motive appears to have been the gaining of a small sum, for which the deceased was insured, in order to forward the prisoner's marriage prospects. The judge spoke in severe terms of the miserable inadequacy of motive and the terrible nature of the crime. To our mind it suggests the irresponsible state of the prisoner's mind, especially when we recall the fact that her sister was an admitted lunatic. It is to be hoped that the Home Secretary will cause an exhaustive inquiry to be made into the mental condition of this unfortunate criminal.

Is There an "Odor Mortis"?

A CURIOUS incident is related in the current number of a French contemporary. A favourite cat was the constant companion of an old lady, who in the course of time became ill and died. A few days, however, before the latter event, occurred, nothing would induce the animal to remain in the room with its mistress. The cat was passed on to a second mistress, and soon became attached to her new owner and her surroundings. In the course, however, of some months later, the second witness fell ill, and ultimately died, and again a few days before her death took place the cat refused to remain with her. Thus, argues our contemporary, the prognosis must be bad in a case where the favourite cat refuses to have anything more to do with its owner. Perhaps the animals detect an "odor mortis."

Embalmers for the Military.

A CURIOUS departure has been taken by the United States' War Department. In deference to the feelings and relatives of such soldiers as may hereafter die on duty in connection with the recent territorial acquisitions, the Department has made arrangements whereby a professional embalmer will be attached to each army transport. The embalmers will be civilians under the control of the Quarter-master General. A portable crematory would appear much more appropriate under the circumstances. We do not profess the superstitious importance to post-mortem repatriation which actuates the Chinese, and armies in the field can ill afford to encumber their transport services with cargoes of embalmed soldiers.

A Stutterer Cured.

THE *New York Medical News* relates the case of a soldier who was afflicted with such a severe stutter that he narrowly escaped rejection at the medical examination. While on service in Cuba he was shot through the mouth, the bullet passing out at the back of the neck. He recovered from the wound and now stutters no more, and he is reported to be busy completing the telling of stories which he had never been able to finish on account of his halting speech. Fortunately there are less drastic means of curing this

distressing infirmity than the one employed in this instance, or cures would be rare.

The Anti-Tuberculosis Crusade in Ireland.

A VERY important meeting, convened by the Royal Academy of Medicine of Ireland, took place on Friday last, the occasion being especially dignified by the presence of the Lord Lieutenant, who occupied the presidential chair. Delegates named by almost every medical, sanitary, and municipal body were present. Resolutions enunciating the principles upon which the tuberculosis crusade ought to be conducted, with which all our readers are familiar and are in accord, were moved by the Registrar-General, the President of the College of Physicians, and other distinguished persons. His Excellency, in his usual happy vein, and with his usual facility of expression, expressed his entire sympathy with the movement, and his belief that it would yield great results. But he made two reservations, first, that it would be a mistake to attempt the formation of a purely Irish organisation to effect that which could be more effectually attained by establishing a branch of the present Association in England; second, that he considers that all proposals for immediate coercive legislation on the subject would be premature and unwise, in which view we entirely concur. The subject of public consumption sanatoria was judiciously avoided by the speaker, inasmuch as it would have raised the question of enormous expense and coercive legislation to which His Excellency referred.

Abortionist Prosecution.

FROM time to time we have commented on the flood of pernicious advertisement let loose upon society under the name of Madame Frain. The real nature of the business thus carried on with unabashed pertinacity in the heart of the metropolis must have become evident to anyone after a glance at the trade circulars sown broadcast by that enterprising lady and her successors. We have long ago protested, in the name of common-sense and law, that it is a ridiculous travesty of justice to prosecute the actual abortionist, while those who incite to the act are allowed to go free. We are glad to see that the police authorities are coming round to that view, that is to say, if one may judge from the fact that they have lately undertaken a criminal prosecution of the notorious Frain group. This step should have a wholesome deterrent effect upon others of the same class, whose name is legion. Clearly the next logical action of the police will be to prosecute the newspapers that aid and abet the commission of felonious acts by the insertion of advertisements that directly or indirectly incite to the act of abortion.

IN the *Bulletin de Therapeutique* Weber states that the nausea, excitant, and other unpleasant sequelæ of chloroform narcosis may be certainly got rid of by administering chloroform water to the patient for as long a period as possible before the operation.

The New "Doctor of Pharmacy."

WE have long since warned the profession that the time is coming when most respectable chemists will dub themselves "Doctor," and one more sham diploma will be added to those of the spectacle vendors, midwives, plumbers, and all the rest. The proposal originated, appropriately, in the land of wooden nutmegs, faked-up eggs, and all other shams, and it was taken up by one or two of the inferior French universities. It is now taken up by Mason College, Birmingham, which calculates that the University of Birmingham (when it has one) will be delighted to rake in that form of grist for its mill. The curriculum to be required from the new "Doctor" is a *voluntary* course of six or nine months at dispensing and bottle-washing. We are gratified but not surprised to note that the journal of the Pharmaceutical Society throws cold water on the scheme and points out that, as a scientific qualification, the new doctorate will be of no use, as it will not be granted by any of the respectable Universities of Great Britain.

Liquid Air as Physic.

THE physicist has of recent years been coming to the help of the physician and surgeon. Liquid air, it is now claimed, can be produced so cheaply that it may be used as a convenient and practicable motive power for the surgeon and dentist. The Americans are trying its local application for ulcerative conditions, and claim to have obtained results "positively wonderful." Possibly this will form an addition to our next edition of the British Pharmacopœia. Meanwhile "fresh air" in this unusual form must be experimented with cautiously.

The Defunct "Index Medicus."

THE efforts made some time since to secure support for that invaluable compilation, the *Index Medicus*, unfortunately failed in their object, and as the inevitable result of this lack of support by the medical profession, its publication has been definitively abandoned. The loss will be severely felt by those who glean in the medical literary vineyard, but there is a ray of hope in the suggestion that the American Medical Association, through its trustees and the editor of its journal, may undertake anew the editing and publishing of the *Index*.

THE RIGHT HON. LORD JAMES of HEREFORD, Chancellor of the Duchy of Lancashire, will distribute the prizes to the students of Charing Cross Hospital Medical School to-day (Wednesday) at 3.30 p.m.

ROSSCLARE, on Lower Lough Erne, has been purchased for the purpose of establishing a consumption sanatorium in Ireland on the Nordach or Miffing system. The situation is all that can be desired for such an institution.

PERSONAL.

DR. C. W. MANSELL MOULLIN has been elected President of the Röntgen Society.

SURGEON-CAPTAIN J. MILES JENNING, Royal Army Medical Corps, has been made a Companion of the Distinguished Service Order for services in the Soudan.

DR. J. ROBERTS THOMSON, F.R.C.P., London, has been placed on the Commission of Peace as a Magistrate for the Borough of Bournemouth.

DR. MITCHELL BANKS, of Liverpool, and Dr. John Sibbald, Lunacy Commissioner for Scotland, received the honour of knighthood from Her Majesty the Queen at Windsor on Friday last.

DR. W. J. R. SIMPSON, Professor of Hygiene in King's College, London, has been nominated as Honorary President of the International Congress of Medicine, to be held in Paris next year.

DR. HORTON-SMITH has been appointed Gulstonian Lecturer, Dr. Cheadle, Lumleian Lecturer, and Dr. Halliburton, Croonian Lecturer for 1900, by the Royal College of Physicians, London.

H.R.H. THE PRINCESS OF WALES, visited the Cheyne Hospital for Incurable Children, of which she is President, on Thursday last, and personally gave a present to every child with a cheering word of sympathy.

THE Society of Arts has awarded the Albert Medal to Sir William Crookes, F.R.S., "for his extensive and laborious researches in chemistry and in physics, researches which have, in many instances, developed into useful and practical applications in the arts and manufactures."

MR. HY. ARCHIBALD STONHAM, M.R.C.S., will have the sympathy of the entire profession. A few days ago he was returning from visiting a patient, when he was savagely assaulted and robbed by two men. Fortunately they were arrested and have been committed for trial at the Thames police-court. Mr. Stonham was mercilessly handled, and the shock to his system has been naturally severe.

AFTER a long term of service Mr. Thomas Bond, M.B., F.R.C.S., has severed his connection with the Westminster Hospital. His connection as surgeon with that Institution has lasted from 1873 to 1899. As a lecturer on medical jurisprudence he has obtained a wide-world reputation at the Westminster School. Mr. A. H. Tubby, M.S., F.R.C.S., has resigned his post of assistant-surgeon, according to a rule of the hospital, with a view of candidature for the vacancy left by Mr. Bond's resignation.

Scotland.

[FROM OUR OWN CORRESPONDENT.]

THE ROWDY RESIDENTS.—At their usual weekly meeting, held a few days ago, the managers of the Edinburgh Royal Infirmary at length arrived at a conclusion as to the facts relating to the horseplay which we have already

alluded to as having occurred in the residency of the hospital, and delivered judgment thereon. As the actual cause which led to the matter being brought under their notice was discovered to have been the work of a few men who had but lately occupied residential posts, but who are now ex-officials, the present members of the staff were let off with a reprimand and the inevitable intimation that measures would be taken and new rules and regulations ordered whereby the control exercised by the Medical Superintendent and the Board over the conduct of residents when off duty would be still further strengthened. The ex-residents who were the culprits, and who at once came forward to bear the blame and to apologise, were gravely reproved, and deprived of their right to make use of their hospital tickets for attendance at the wards or clinics for the next six months. The crucial point lies in the imposition of new restrictions to be laid upon the private life of the resident medical and surgical staff of the future. The more numerous the rules the greater will be the inducement to evade or break them. The less confidence reposed in the residents by the Board, the more likely will displays of unruliness and outbursts of animal spirits be. "Ragging" is a subject of curious etiology. It seldom does any harm; often much good. He who cannot understand its underlying import, and who by "cutting up rusty" stimulates further attentions from his colleagues, must have a discontented mind. Exuberance of youth, newly freed from undergraduate fetters, is but seldom vented in any unfriendly or malicious sense; it is not to be compared to the horseplay which is far too common possibly to be encountered by them in acts of unprofessional etiquette in their later days.

PENDING the completion of the new and palatial City Hospital which Edinburgh is building for herself just out of her present limit towards the south, the Town Council's Public Health Committee approved of a scheme whereby a limited number of pathological reports on specimens sent in by the town health authorities should be obtained from the Research Laboratory of the Royal College of Physicians for a temporary period.

STUDENTS AND BELVEDERE CLINQUES.—The Hospital Committee of the Glasgow Corporation has had under consideration the question of charging fees to students who receive instruction at Belvedere Fever Hospital. Dr. Johnston, the superintendent, having made inquiries in various cities and towns, reports in regard to the information obtained from these places that "the teacher is paid by the students either directly or indirectly in all places except Edinburgh, and even there it is proposed to alter the custom and come into line with the general practice. Except in three hospitals (Edinburgh, Manchester, and Liverpool), where the teaching is done by a visiting physician, the medical superintendent of the hospital takes personal conduct of the classes." Dr. Johnston further reports, as well as suggests, to the Hospital Committee, that in view of the near completion of Ruchill Hospital, that the London system where three guineas (£3 3s.) are paid for sixteen demonstrations, and £4 4s. for twenty-four demonstrations might be adopted in Glasgow. It would perhaps be more prudent to speak of charging an already over-charged set of students for clinical instruction in infectious diseases, were such charge limited, say to £1 1s., but the suggestion of fixing it at £3 3s. to £4 4s. has not unnaturally raised the ire of students. And it may be asked what do medical men receive from the Glasgow Corporation for reporting a case of infectious disease? Half-a-crown payable at the end of three months! But should they neglect to report a case, the Corporation can inflict a fine of forty shillings. Another question arises out of the proposal. To whom do these heavy fees belong when imposed? Do they go into the pocket of the teacher (superintendent) or into the coffers of the corporation? As the teachers of the practice of medicine are able to give the necessary theoretical lectures on fevers, it will not be necessary for the time of the superintendent of a fever hospital to be taken up in delivering lectures on cases which can be demonstrated at the bedside of infected patients.

Manchester.

[FROM OUR OWN CORRESPONDENT.]

VICTORIA UNIVERSITY.—Saturday, July 1st, was "Degree Day." A large and brilliant gathering assembled to witness the interesting ceremony. Among the recipients of Honorary Degrees was Professor T. Clifford Allbutt, Dr. Edward Schunck, and Mrs. Henry Sidgwick. An unusually large number of candidates were presented as qualified for degrees, or in connection with distinctions gained. This year large contingents have come from University College, Liverpool, and Yorkshire College, Leeds. Six received the degree of M.D., gold medals being granted to three.

CREMATION.—The authorities of the Manchester Crematorium, one of the most satisfactory in the country, have just issued a circular stating that several deaths have lately occurred among their original shareholders, and that their friends have not resorted to cremation but to ordinary interment. It is suggested, therefore, that the supporters of cremation should distinctly record their desire to be cremated after death, and forms have been circulated with the request that one be forwarded filled up to the offices, and the other deposited with the will of the signer. This is reasonable, although hardly a pleasant request.

DALTON'S TOMB.—The Council of the Manchester Literary and Philocephical Society have issued a statement that Dalton's tomb in one of the city cemeteries has fallen into great neglect. The monument was provided originally out of the Dalton Memorial subscriptions in 1853, but no existing body now seems to be responsible for its proper preservation. It is rightly felt that the continued neglect of the resting-place of one of Manchester's greatest worthies would be scandalous and discredit, and an appeal is made for subscriptions to provide means by which repairs may be made as required.

MANCHESTER THERAPEUTIC SOCIETY.—This is the only society in Britain devoted exclusively to the study of matters therapeutical. At the last annual meeting the following officers were elected for the session 1899-1900. President, Dr. Dreschfeld; vice-presidents, Dr. Dixon Mann, Dr. Wilkinson; hon. treasurer, Dr. Williamson; hon. secretary, Dr. Wild; committee, Dr. A. Brown, Dr. F. J. H. Coutts, Dr. Kelynack, Dr. Vipont Brown, Dr. Goodfellow, Dr. J. E. Platt.

Literature.

HAYES'S INFECTIVE DISEASES OF ANIMALS. (a)

SOME years ago Professor Friedberger and Fröhner, of the German Veterinary Schools, brought out their excellent *Lehrbuch der Speciellen Pathologie und Therapie der Haustiere*, which has been so favourably received that a translation into French by the Veterinary Professor Cadiot and M. Ries was published in 1891, and, if we mistake not, an English translation has also been issued in America. Captain Hayes, who is well known as a popular writer on horses, now gives us a portion of the work in English, and the first volume is sent out, the second being promised to follow before long. To those who cannot read the book as it appeared in German or in French, this English edition will prove of some service in giving an idea of the opinions entertained among German veterinary surgeons with regard to the more important infective diseases of animals, though to do justice to the original authors and the title of their book it would have been better if the *whole* had been translated as in the French edition. The entire volume before us is not occupied with these infective disorders, a considerable portion being allotted to such chronic constitutional diseases as anæmia and chlorosis, leucæmia, scurvy, gout, diabetes,

(a) "Infective Diseases of Animals." Translated from the German and Edited by M. H. Hayes, F.R.C.V.S. with notes on Bacteriology, by Dr. G. Newman, D.P.H. Vol. I. London: W. Thacker and Co.

&c. The infective maladies treated of include all those with which we are familiar, and as some of these, such as glanders, rabies, anthrax, tuberculosis, and the variolæ of two or three species of animals, are transmissible to mankind, the work possesses a certain interest for medical men, who will find some useful information with regard to these serious disorders. Friedberger and Fröhner have treated them with that thoroughness and ability which is so conspicuous in the work of German veterinarians, and though we may be inclined to differ from them to some extent on points of pathology, yet, on the whole, their views may be accepted as based on intelligent observation and experience. The translator appears to have accomplished the task he undertook in a satisfactory manner, and has added notes here and there throughout the work when he thinks it necessary to correct, add to, or illustrate the statements of the authors. In these notes there are one or two little slips which a better acquaintance with the subject would have prevented. For instance, at page 420, in a note appended to rinderpest, the translator says:—"Our exact knowledge of the occurrence of rinderpest in England dates from 1865, in which year this bovine scourge was imported from Revel by Russian cattle." If there is any fact better established than another it is that this decimating disease was present in this country for several years, and on several occasions during the last century—of this there is ample proof in Dr. Fleming's "History of Animal Plagues." (a)

An interesting appendix to the volume contains a notice of some diseases which are not dealt with in the German edition, such as the South African horse-sickness, the Indian surra, and a disorder of the larger domestic animals caused by ticks in Queensland and Jamaica, as well as in this country; but while alluding to these, the Translator makes no mention of the serious losses caused in certain parts of Africa by the tse-tse fly. The notes on bacteriology, by Dr. Newman, of King's College, will be found useful, as they are clear, brief, and informing on this important subject. Altogether, the book can be recommended to those for whom it was written, as a pretty correct exposition of our present knowledge of the diseases with which it deals, presented in a convenient and readable form.

NEW SYDENHAM SOCIETY'S ATLAS OF PATHOLOGY. (b)

THIS instalment of the above well-known Atlas deals with a very interesting subject—"Lymphadenoma, or Hodgkin's malady." It consists of three beautifully coloured plates, reproduced from drawings by Sir R. Carswell, of a typical case of the disease in the Hôpital St. Louis, Paris. The first plate represents a dissection of the side of the neck and axilla, showing the chain of enlarged glands. The second gives a surface and sectional view of the spleen, which was closely studded with brain-like nodules. In the third plate we find a faithful and brightly coloured representation of the appearance of an enormous mass of glands that lay beneath the liver and raised up the duodenum, pancreas, &c., into close contiguity with that viscus. As regards the letter press that accompanies these plates it calls for little remark being purely explanatory. The title, "Infective Disease of the Lymphatic System," would, however, seem unjustified as the most recent researches have failed to establish the "infective" nature of Hodgkin's disease—unless the word be used in the sense in which it is sometimes applied to carcinoma. But in that case one would have to class carcinoma as "an infective disease of the mammary gland" which is assuredly incorrect so far as our present knowledge goes. Again, the case illustrated was not subjected to microscopic examination, and the pathologists who did the post-mortem regarded it as one of "cancer," which in the opinion of the writer of the letter press was not unjustified in the case of the tumour beneath the liver at least. It is also very much to be regretted that no

effort has been made to illustrate the microscopic anatomy of the disease, and that no discussion of such important points as the correct nomenclature and the relation to Leukæmia has been introduced. These are grave defects in the work from the scientific standpoint. Whilst fully considering the artistic merit of the drawings, we feel it our duty to express the opinion that in order to render them of educational value something more than mere reproduction is necessary, and that something has been left undone by the New Sydenham Society.

THE OXFORD ENGLISH DICTIONARY. (a)

THIS double section contains the central portion of the letter H, of which letter it constitutes one-fourth. It contains 2,439 main words, 374 combinations explained under these, and 714 subordinate entries—3,527 in all. These words are illustrated by no less than 13,768 quotations, a number far in excess of any other dictionary, and a good evidence of the thoroughness with which the work is being done.

MUTER'S ANALYTICAL CHEMISTRY. (b)

AN eighth edition is of itself equivalent to a certificate of popularity, and in respect of the value of scientific manuals the *vox populi* may certainly be accepted as the *vox Dei*. This concisely written but very comprehensive manual deals with the practical aspects of the organic and inorganic chemistry with the qualitative and quantitative, on the lines adopted at the South London School of Pharmacy. Our familiarity with the earlier edition of this invaluable work enables us to state with assurance that, in the limits which the author has assigned to himself it is entirely without a rival. A student who takes this work as his guide and works through it cannot fail to become familiar with all the chief developments of analytical chemistry from the simplest operations upwards, including many organic questions usually overlooked in works of this kind. Originally written for the use of students of pharmacy, it will prove not less serviceable to medical students preparing for university examinations, while as a work of reference, it may be relied upon by physiologists and studious practitioners. The reactions have been adapted, where necessary, to the B.P. (1898). We note, with some curiosity, the statement that the index has been intentionally omitted in the present edition, experience having shown that an index to a practical book leads to such an immense number of cross references as to be bewildering. We are hardly able to follow this reasoning, though it may be conceded that the table of contents will *a la rigueur* answer all the purposes of an index.

LEAF ON THE LYMPHATIC GLANDS. (c)

WE have no hesitation in affirming that this little work, with its numerous coloured illustrations, is a valuable contribution to anatomical science and incidentally to surgery and medicine. It is not that the painstaking author has made any particularly original discovery in respect of the glands under consideration, indeed, he gives a wide berth to certain points, such as the course of the various lymph streams, respecting which one would have liked to hear more. What he has done, however, is to systematise our knowledge of these groups of glands and to confirm and complete by actual dissections, details already more or less adequately treated in current text-book.

By the aid of a series of diagrams the position of the main groups of lymphatic glands is clearly indicated,

(a) "A New English Dictionary on Historical Principles, founded mainly on the Materials collected by the Philological Society." Edited by Dr. James H. H. Murray, with the assistance of many Scholars and Men of Science. Heel-Hod. Volume V. Oxford: At the Clarendon Press. London, Edinburgh, Glasgow, and New York: Henry Frowde.

(b) "A Short Manual of Analytical Chemistry." By John Muter, Ph.D., F.R.S.E., &c., Analyst to the Metropolitan Asylums Board, &c. Eighth Edition. London: Baillière, Tindall, and Cox. 1898.

(a) "Animal Plagues: their History, Nature and Prevention." Vols. I and II. By George Fleming, C.B., LL.D., F.R.C.V.S. London: Baillière, Tindall and Cox.

(b) "New Sydenham Society's Atlas of Pathology." Fasciculus XII. London: H. K. Lewis. 1899.

and the bearings of these data on surgical practice made plain. To some of the groups of glands the author has ventured to give new names, a somewhat risky proceeding though they indicate with sufficient accuracy the positions occupied by the various glandular groups.

GILLESPIE ON DIGESTION. (a)

A WORK of this calibre is rather a tough morsel for the reviewer to digest. It covers such a large field, and comprises such a disconcerting array of facts, statements, and mere hypotheses that it defies, while it invites, criticism. The author evidently has very settled views on diet, and these have led him to investigate the phenomena of digestion with a perseverance and a thoroughness which are as rare as they are admirable. The work represents an attempt, something more than an attempt indeed, to describe in the brief compass of some 425 pages, the general laws governing digestive processes in all living bodies. We are invited to regard the organisms as an association of cells, working on trades union principles, and grouped according to occupation *qua* function. In the great question of nutrition it is impossible to lose sight of the fact that individual and racial idiosyncrasies play an important part in determining what from an alimentary point of view, is good, and what is bad. Therefore, in laying down rules a margin of divergence must be conceded, and it is the role of the physician to adapt general rules to individual cases. We do not propose on this occasion to follow the author in his speculations as to the influence of diet on temperament. We have a shrewd suspicion that the influence is the other way about, and that it is the temperament that governs the choice of diet and not the other way about. There is one point, however, to which the author calls attention, which is worthy of notice—viz., that too rich a diet, yielding to the body a greater income than suffices to balance its current expenses, may lower the bodily functions to a point below that appertaining to the slightly underfed, but not ill-fed individual.

We are first initiated into ancient theories of digestion, a subject in which our ancestors took considerable interest, though they could hardly be said to see even "through a glass darkly." The influence on diseased conditions of modifications of diet could not escape the notice of those vigilant observers who, to some extent, made up for their lack of scientific knowledge, by close clinical observation. One has only to read Galen to see to what a pitch of perfection clinical observation was carried in what we are pleased to call the Dark Ages. The next chapter deals with the digestive process in plants which, the author suggests, may serve to indicate the modes and means by which protoplasm in all vegetable and animal cells can most easily and economically procure a "living wage." It is but a step from the carnivorous plant (which furnishes material for a very interesting chapter) to the animal, and this drags us at once to the important subject of ferments and ferment action. The author has adopted the standard classification into organised and unorganised ferments, respecting which he has much of interest to say, but recent researches on yeast, for example, render it probable that our views will shortly undergo profound modification, indeed the division between the two classes of ferments may prove as unreal as that which once existed between organic and inorganic chemistry.

The author deals very fully with food elements and their digestive disintegration, and gives some very elaborate tables to show the influence of experimental and other circumstances in respect of the quantity and quality of the digestive juices. One stands aghast at the labour which many of these investigations must have entailed, but they confer a special value on the work, which will remain a standard work of reference for future generations of writers on this and germane subjects.

A carefully argued chapter on metabolism leads us to the more practical section of the work. In the chapters on "Dietetics and Animal Heat," the use of

stimulants and foods in general we have a large amount of valuable information, embodying the latest views on what we may term physiological alimentation. The analyses of the principal groups of food stuffs is given and their nutritive value discussed. Readers who lack the patience or desire to study the more recondite problem of digestion may be recommended to take cognisance of the concluding chapters on "Foods" which contain many practical deductions, expressed in a pleasant chatty manner, well calculated to make it easy of digestion.

MOYNIHAN ON RETRO-PERITONEAL HERNIA. (a)

THIS volume is a review of the anatomy and surgery of the various peritoneal fossæ, with special reference to the development of strangulation of abdominal viscera in them. The author deals in addition with the hernia through the foramen of Winslow.

In discussing the duodenal peritoneal fossæ, he describes no less than nine varieties of these pouches in the region of the duodeno-jejunal flexure. After an exhaustive account of the anatomy and origin of the folds and fossæ, the occurrence of duodenal herniæ is treated. This form of internal strangulation has two distinct varieties, one where the increase of the hernial sac is to the left of the middle line, and the other—the less common—to the right. The author discourages the use of the term "duodeno-jejunal" hernia, preferring that of "left" or "right" duodenal hernia, and with this we entirely agree. It would appear that duodenal herniæ are the most frequent of all the herniæ into peritoneal fossæ, and therefore the practical hints given are of importance, especially that of the necessity of dividing the neck of the sac only after two ligatures have been applied, because of the large vessel that is invariably present at this situation.

The fossæ about the cæcum have been to a very great extent mystified by the variety of descriptions that have been given of them, but Mr. Moynihan has discussed them with distinct clearness.

Probably the chief importance of these peritoneal pouches is the liability for the vermiform appendix to become incarcerated in one of them, and the subsequent possibility of inflammation being thereby induced. This may be a not infrequent determining cause of acute appendicitis.

The remaining fossa in the series is that known as the intersigmoid, and the author shows that hernia into this is of very rare occurrence, as he is only able to cite two cases from English literature, but these are typical ones.

The anatomy of the foramen of Winslow is well dealt with, and the passage of bowel through it discussed.

There is an excellent bibliography of the subject of retro-peritoneal hernia, and the book concludes with a most interesting and beautiful series of photographs of the various specimens of such herniæ in the London and Provincial Museums, together with one from the practice of Dr. Louis Mitchell, of Chicago.

We warmly congratulate the author on the contribution, and that so exhaustive a one, which he has made to surgical literature on this most interesting class of intestinal obstructions.

THE CHEMICAL AND BIOLOGICAL ANALYSIS OF WATER. (b).

IN the pages of THE MEDICAL PRESS AND CIRCULAR some time since we reviewed at some length "The Analysis of Milk and Milk Products," by Messrs. Pearmain and Moor. The review was, on the whole, complimentary, and we feel that we ought to state at once that, well as that instalment was done, this second part on water analysis is even more deserving of praise.

The authors in their introduction express a sort of

(a) "The Natural History of Digestion." By A. Lockhart Gillespie, M.D., F.R.C.P. Edin. Lecturer on Materia Medica and Therapeutics in the Medical School of the Royal Colleges, Edinburgh, &c. London: Walter Scott, Ltd. 1898.

(a) "On Retro-peritoneal Hernia, being the 'Arris and Gale' Lecture on the Anatomy and Surgery of the Peritoneal Fossæ." By B. G. A. Moynihan, M.S., Lond., F.R.C.S., Eng.
(b) "The Chemical and Biological Analysis of Water," by T. H. Pearmain and C. G. Moor, being Part II. of "The Analyses of Food and Drugs." London: Baillière, Tindall, and Cox. 1899.

apology for including water among foods. Why? Surely it is the food, *par excellence*, by which we live and exist, and by the aid of which all other foods are alone assimilated. As it is largely consumed *per se*, it becomes necessary that we should perfect our knowledge of its analysis, unfortunately one of the hardest problems presented to the professional analyst.

The authors divide the analysis of water into three divisions—(1) Chemical Analysis, (2) Biological Analysis, and (3) Physical Analysis.

They very properly say that "undoubtedly the chemical examination is usually the most important." Of late years too much stress has been laid upon bacteriology in connection with water analysis, but the reviewer, from practical experience, can only endorse the views of the authors of this work, who find that bacteriological investigations, as regards water examination, should generally be taken as an aid to drawing an inference. There was some danger that too little attention would be given to its chemical analysis, and that, carried away by the wonderful development of bacteriological science, we should lose sight of those chemical indications which had been the sheet-anchor of the analyst. This, so far, is happily at an end, and each branch has taken again its proper place. The chief use that the writer can see, in our present knowledge of the bacteriology of water, is the isolation and identification of certain pathogenic organisms, such as the comma bacillus, typhoid bacillus, &c. The work, however, should only be undertaken by the bacteriological specialist. In speaking of this the authors say: "An analyst, whose practice does not involve the constant study of the organisms which are in question, in the various phases of their life history, can do no worse service to himself or his clients than to undertake work which includes their identification." This is perfectly true. Even in the hands of experts, the information is of the most meagre description.

The numeration of bacteria, at first thought to be of immense import, is, by our present state of knowledge, of no more significance than any one of the chemical processes, such as the determination of the albumenoid ammonia.

Of late years the microscopic appearance of the suspended matters has been neglected. The determination of the larger forms of microscopic life in town supplies has been ignored. Great importance was formerly attached to this, which may be properly considered as part of the physical examination of a water. In the days of Hassel, &c., such examinations were considered as of the highest significance, but with the rise of bacteriological science they seemed to disappear from the expert's reports. Perhaps the men of half a century ago, although excellent microscopists, did not possess sufficient knowledge to properly apply the investigation to water analysis. It has now taken its proper level, and analysts, if they find this kind of life, are enabled to diagnose its bearing upon the condition of the water. Thus, if the microscopist finds the *meggitos alba*, or sewage fungus, in a water, he knows it is a sure sign of the presence of a large amount of putrid organic matter. If he finds fungi he knows they cannot exist in the water itself, but are formed in decaying organic substances. The natural habitat of the crustaceæ is solid decaying matter, and in presence of large quantities of decomposing organic debris, Messrs. Pearmain and Moor dwell upon this part of water analysis to some length, and some excellent drawings from the pencil of Miss Ethel Smith White are added, which make this part of the book very practical.

The "Chemical Examination" part of the work is very complete and up to date. In estimating free and albumenoid ammonia the authors seem to have neglected the precaution of performing these operations in an ammonia-free atmosphere. The omission of some precautions in this direction may account for the amusing discrepancies found in the results of different analysts, with the same water; yet the process is so simple and well understood that such discrepancies should not exist. Some analysts go so far as to erect a closet for the distillations in con-

nection with this process. The apparatus suggested by C. Tichbone (Sc. Proc. R.D.S., Vol. III., Pt. S) is so simple and yet so effective in its action that it should be more generally used.

Over 50 pages of the book before us are taken up with the consideration of the bacteriology of water. It is very concisely and tersely put, and the authors run on a fairly even keel as regards the rather controversial questions connected with bacteriological water analysis. We think they have done it full justice, without attaching undue value to its practical bearing. They do not underrate the pathological value of the science as applied to such an important food as water, but it is quite clear that the authors have a grasp of the subject upon which they are writing. This part of the work is exceedingly well written, and will be found of immense use to students of sanitary science.

NEW BOOKS AND NEW EDITIONS.

THE following have been received for review since the publication of our last monthly list:—

BAILLIERE, TINDALL, AND COX (London and Paris).

Urinary Analysis and Diagnosis. By Microscopical and Chemical Examinations. By Prof. Louis Heitzmann, M.D. Pp. 254. Price 10s. 6d.

The Analysis of Food and Drugs. By T. H. Pearmain and C. G. Moor, M.A., F.C.S., F.I.C. Second Edition. Pp. 236. Price 3s. 6d.

Essentials of Modern Treatment of Disease. By K. M. Nadkarni, editor of the "Indian Medico-Chirurgical Review." Pp. 462. Price 5 rupees.

The Quarterly Journal of Inebriety. Edited by T. D. Crothers, M.D. Vol. XXI. Pp. 221.

Traité de Médecine et de Thérapeutique, sous la direction de MM. Brouardel et Gilbert tome sixième. Pp. 652. Price 12 francs.

BLAKISTON, SON, AND CO. (Philadelphia).

The Newer Remedies, a Reference Manual. By Virgil Coblentz, A.M., Ph.D., F.C.S. Third Edition. Pp. 147. Price 1 dol.

THE CHEMIST AND DRUGGIST OFFICE (London).

Proctor's Practical Testing, revised with the British Pharmacopœia, 1898. Price 2s. 6d. net.

J. AND A. CHURCHILL (London).

Selected Papers on Stone, Prostate, and other Urinary Disorders. By Reginald Harrison, F.R.C.S. Pp. 190. Price 5s.

THE F. A. DAVIS COMPANY (Philadelphia and New York).

An Epitome of the History of Medicine. By Roswell Park, A.M., M.D., Pp. 384. Price 2 dols.

CHARLES GRIFFIN AND CO., LIMITED (London).

The Diseases of Children, a Clinical Handbook. By George Elder, M.D., F.R.C.P.Ed., and J. S. Fowler, M.B., F.R.C.P.Ed. Pp. 391. Price 10s. 6d.

A Medical Handbook. By R. S. Aitchison, M.D., F.R.C.P.Ed. Pp. 363. Price 8s. 6d.

FREDERICK J. HANBURY (London).

The Flora of Kent. Being an Account of the Flowering Plants, Ferns, &c., with Topographical, Meteorological, and Botanical Notes of the County. By F. Janson Hanbury, F.L.S., and Ed. S. Marshall, M.A., F.L.S. Pp. 444.

HENRY KIMPTON (London).

Gleet and Chronic Diseases of the Urethra. By Gerald Dalton, M.S.A.Lond. Pp. 48. Price 1s.

JAMES MACLEHOSE AND SONS (Glasgow).

Chemical and Microscopical Aids to Clinical Diagnosis. By Carstairs C. Douglas, M.D., B.Sc. Pp. 258.

KEGAN PAUL, TRENCH, TRUBNER, AND CO. (London).

Bradshaw's Dictionary of Bathing Places, Health Resorts, &c., for 1899. Pp. 372. Price 2s. 6d.

Evolution by Atrophy in Biology and Sociology. By M.M. Demoor, Massart, and Vandervelde. Translated by Mrs. Chalmers Mitchell. Pp. 322. Price 5s.

LONGMANS, GREEN, AND CO. (London and Bombay).

The Serum Diagnosis of Disease. By R. C. Cabot, M.D., Mass., U.S.A. Pp. 134. Price 7s. 6d.

A Manual of Surgical Treatment. By Watson Cheyne, F.R.C.S., F.R.S., and F. F. Burghard, M.D., F.R.C.S. In six parts. Part I. Pp. 286. Price 10s. 6d.

METROPOLITAN ASYLUM BOARD.

Annual Report of the Statistical Committee for 1893 with Appendices in two volumes.

MEDICAL PUBLISHING COMPANY, LIMITED (London)

Pneumonia Alveolaris and its Relations to General Medicine. By John Fitzgerald, L.D.S. Pp. 62

OLIVER AND BOYD (Edinburgh).

Anæmia and Some of the Diseases of the Blood-forming Organs and Glands. By Byrom Bramwell, M.D., F.R.C.P.Ed. Pp. 450. Price 12s. 6d.

THE OPEN COURT PUBLISHING COMPANY (Chicago).

The Psychology of Reasoning. By Alfred Binet. Translated from the French by A. G. Whyte, B.Sc. Pp. 191.

YOUNG J. PENTLAND (Edinburgh and London).

The Murmurs of Mitral Disease. By E. Mansfield Brockbank, M.D., M.R.C.S. Pp. 47.

Aseptic Surgery. By C. B. Lockwood, F.R.C.S. Second Edition. Pp. 264. Price 4s.

The Edinburgh Medical Journal. Edited by G. A. Gibson, M.D., F.R.C.S.Ed. New Series. Vol. V.

SAMPSON LOW, MARSTON AND CO., Limited (London).

Handbook of Medical Gymnastics. By Anders Wide, M.D. Pp. 374. Price 10s. 6d.

Twentieth Century Practice, an International Encyclopædia of Modern Medical Science. Edited by Thos. Stedman, M.D. Vol. XVI. Infectious Diseases.

THE ROYAL BRITISH NURSES' ASSOCIATION.

Roll of Members for 1899. Pp. 132.

JOHN WRIGHT AND CO. (Bristol).

Our Baby: for Mothers and Nurses. By Mrs. Langton Hewen. Sixth Edition. Price 1s. 6d.

An Introduction to Dermatology. By Norman Walker, M.D., F.R.C.P.Ed. Pp. 247. Price 8s. 6d. net.

Correspondence

We do not hold ourselves responsible for the opinions of our correspondents.

COLONIAL DEGREES: REGISTRATION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—On April 29th you were kind enough to publish a letter from me, stating that the Medical Council, acting on the advice of Mr. Muir Mackenzie, had passed a resolution confirming the action of the Registrar in refusing to register the diploma of F.R.C.S.I. as an additional qualification on the Colonial List, and I stated then that I had appealed to the Privy Council on behalf of the applicant.

The appeal, I am glad to say, has been successful, and I have just received a communication from the Privy Council Office, informing me, by direction of the Lord President of the Council, that the General Medical Council have intimated to His Grace that on the 6th inst. they resolved to accede to the application, and have directed the Registrar, in future, to register additional or higher qualifications on the Colonial List.

I have not yet received any intimation from the Registrar of the General Medical Council, but I see in the report of the proceedings that Mr. Muir Mackenzie stated that his first opinion was given without a full knowledge of the facts before him.

In my appeal to the Privy Council, I did not in any way add to the application made to the General Medical Council, which, I take it, should have been submitted to Mr. Muir Mackenzie, when his opinion was asked, as refusal to register a qualification might, and probably has, inflicted injury on an applicant legally entitled to registration.

Thanking you and the members of the General Medical Council, who assisted in effecting this registration.

I am, Sir, yours truly,

CHARLES FREDERICK KNIGHT, M.D.

Edinburgh, June 29th, 1899.

Small-pox in Hull.

It appears from a statement made by the President of the Local Government Board last week in the House, that of the 83 cases of small-pox at Hull, as to which the Board have received information, 62 showed evidence on examination of having been vaccinated, and 21 appeared to have been unvaccinated. The rate of death among patients exhibiting evidence of vaccination has been 9.7 per cent., whilst among those exhibiting no evidence of vaccination it has been 57.1 per cent.

New Surgical Appliances.

NEW UTERINE DOUBLE CURETTE.

By DR. ALEXANDER DUKE,
Cheltenham.

For the various operations requiring curetting I think it will be found an advantage to possess an instrument which will do double the work effectually and in a much shorter time.

The curette depicted, made for me by Messrs. Evans and Wormull, Stamford Street, London, will be found in practice to act well, and with ordinary care can do no injury to uterus. It consists of two curettes or ring knives (lying inside each other while instrument is closed) the blunt edges alone presenting. The width of outer loop from side-to-side measures little more than half an inch, so that that amount of dilatation of "os" and cervix will be found sufficient to admit the blades to pass into uterus while steadied by tenaculum or volsellum. The milled nut on outer side being then released by fingers, the weak spring action will be found sufficient to open blades to the extent allowed by nut and bring the cutting edge or edges into close proximity with uterine walls. (The depth of cutting edge exposed can be graduated to a nicety by means of the milled nuts, the necessary number of half turns having been counted before instrument is introduced.)

The blunt edge of inner curette should project slightly from outer during introduction; there will then be no danger of incising the cervix while passing instrument into uterus. The blades can also be used by rotation while withdrawing curette slowly from uterus, thus making the complete removal of endometrium far more certain and avoiding the necessity of having at some future time to repeat the operation. The instrument can be used either as a single or double curette by keeping the blades almost closed or opened respectively.

Laboratory Notes.

L'EAU D'OREZZA.

WE examined this water nearly a quarter of a century ago, and found it to contain a considerable percentage of iron, both as carbonate and protoxide, calcium carbonate, magnesium, carbonate with traces of potassium, and sodium chloride. We put it through present-day tests with some curiosity and found its leading characteristics had undergone but the slightest variation during this long interval, showing it to be what is claimed for it, a natural ferruginous water of stable character and of decided value in anæmia, chlorosis, and general debility. It contains more free carbonic acid, and is, therefore, more effervescent than most others of its class, a point in its favour which invalids will readily appreciate.

It seems passing strange that a natural product of such excellence should be comparatively so little known in this country, while on the Continent it is so popular a remedy with the profession. It issues from a mountain spring nearly 2,000 feet above sea level in the island of Corsica, whence it is bottled and conveyed to the various depôts in the usual manner. Probably it may be destined to a fuller appreciation in the future, as Sir Hermann Weber speaks highly of it in Clifford Allbutt's new "System of Medicine," and recent writers have recognised its therapeutical value. The shippers and

agents for this country are Messrs. Mark, Whitwill, Son and Judge, and it is obtainable at all chemists and mineral water dealers.

ELIXIR PHOSPHORUS (HORN).

THIS preparation may be described as a clear, stable aromatic fluid of syrupy consistence, containing, according to the prospectus, a fiftieth of a grain of free phosphorus in each fluid drachm, an assertion which is approximately borne out by the results of chemical analysis, and which also shows that the preparation contains no chloroform, ether or oil. The elixir is miscible with water, without any turbidity, and the mixture is free from any unpalatable taste. This is not the place to dilate upon the therapeutical application of free phosphorus, but when it is desired to administer the drug, this preparation appears to offer certain advantages. It is manufactured by Mr. O. E. Horn, D.Sc., of Bournemouth.

CHOCOLATE-COATED MEDICINE TABLETS.

MESSRS. PARKE, DAVIS and Co. have favoured us with samples of sundry recent additions to their list of chocolate-coated tablets, notably (1) tablets of calomel, ipecacuanha, bicarbonate of soda and bismuth, for infants; (2) cubeb compound tablets, for gonorrhœa; (3) euonymin, podophyllin, and calomel tablets; and (4) calomel and bicarbonate of soda.

These chocolate-coated tablets are characterised by perfect uniformity in point of size and weight (for each kind); and by their, pharmaceutically speaking, perfect finish. They represent, indeed, "le dernier cri de la pharmacie." The remorseful incontinent will welcome the tablet of cubeb compound as a pleasant change to the nauseous pastes and mixtures with which the old-fashioned practitioner beguiles his ailment, and children will appreciate the "corrective" tablets as a heavenly substitute for the teaspoonful of liquid redolent of rhubarb and other medicaments, good, no doubt, in their way, but not popular with unreasoning childhood.

Medical News.

Royal Institute of Public Health.

THE annual Congress takes place this year at Blackpool, under the presidency of the Marquis of Lorne, K.G., the Mayor of Blackpool being honorary president, and Dr. Jasper Anderson is honorary secretary of local committee. A Health Exhibition in connection with the Congress will be held from September 21st to October 14th, of appliances connected with public health, special attention being paid to those for the abatement of smoke, the object being the much-needed improvement of the smoke-polluted air of our towns and cities, and the economical consumption of fuel. There will also be a special section for public and private means of preventing fire, and of appliances for saving life from fire. Mr. W. G. Larkins, who was the curator and manager of the Exhibition at the Royal University in connection with the Dublin Congress last year, has been appointed to the same responsible position at Blackpool, and may be communicated with at the Public Health Office, Blackpool.

Chelsea Hospital for Women.

WE are asked to announce that this institution will be closed to in-patients from the middle of July to the end of September in order to permit of the following necessary alterations and improvements being carried out:—Enlargement and modernising of operating theatre, new hot-water service, new lift, installation of electric light. These improvements will cost nearly £3,000, and in view of the great pressure at which the work of the hospital is carried on, they can be no longer delayed. An appeal is being made for assistance towards defraying this expenditure. The out-patient department will be closed during August only.

More "Peculiarities."

FREDERICK NORMAN and his wife, members of the

"Peculiar People," have been committed for trial on a charge of causing the death of a female child, aged 5, by withholding medical aid. The medical evidence showed death to have resulted from exhaustion consequent upon an attack of pleuro-pneumonia.

The General Medical Council and the Certification of Midwives and Opticians.

THE Corporate and Medical Reform Association request us to point out that in reply to the memorials, the General Medical Council has adopted resolutions implying that for registered practitioners to take part in such certification is "improper conduct," within the purview of the Council (*vide Lancet* and *B.M.J.*, June 10th, 1899). In 1893 the Council's Executive Committee framed for the Obstetrical Society a form of licence for midwives which the Council approved and the Society adopted. As the Medical Act denies recognition of the right to practice midwifery to persons not registered under the Act, these proceedings of the Council and all its proceedings recognising such licences, are illegal. Yet how can the General Medical Council, it is asked, after sanctioning these licences, bring itself to convict practitioners of "infamous conduct" for issuing them? But if it will not convict one registered practitioner for examining or licensing midwives, how can it convict another for examining and passing opticians in sight-testing? And is not the sole escape from this embarrassing dilemma which we can anticipate a predetermined acquittal upon either charge? The General Medical Council has thus, by refusing their power to rescind its illegal proceedings, repudiated its judicial character, and destroyed its judicial competency as to the conduct of practitioners in examining and certifying either midwives or opticians. The direct representatives are in a hopeless minority, and the Council has twice in three sessions refused to recommend an increase in their number, and has also refused to amend, in accordance with the terms of the Medical Acts, its illegal form of return of corporate members, which enables them to be illegally returned. Under such circumstances vigorous measures are stated to be urgently needed to protect the rights of the profession and the public safety, and the remarkable success and general approval attained by the memorials is a guarantee of the success of more energetic and no less constitutional proceedings. An address or petition to the Privy Council to exercise its authority under the Medical Acts will be submitted for consideration.

Death Under Chloroform.

AN inquest was held last week at Sudbury, on a man, æt. 34, who had died at the St. Leonard's Hospital during the administration of chloroform previous to an operation necessitated by an injury to the hand. There was the usual struggling, which subsided, only to be promptly followed by respiratory failure. The report before us gives no information as to the amount of chloroform given in the matter of administration, but it is plain that the pernicious, so-called "open" method was followed. Unfortunately, these are matters which coroners juries are ill-fitted to discuss and appreciate, so the usual verdict was returned in accordance with the medical evidence.

Recalcitrant Guardians.

THE Dewsbury Board of Guardians have instructed their vaccination officer not to take any proceedings against defaulters under the Vaccination Act, the Local Government Board's instructions to that officer to the contrary notwithstanding. It remains to be seen what course the central authority will take to put the insubordinate guardians in order.

Diphtheria in Staffordshire.

AT Longton, in Staffordshire, upwards of 550 cases have been notified during the last few months with 102 deaths. The Medical Officer of Health personally notified the Sanitary Committee that unless they build an infectious disease hospital, do some radical work to the drains, concrete building sites, watch the places where refuse tipping is going on, they must consider that they are only playing at sanitary reform, making matters on the surface to please the eye, but not to please the eye of intelligence.

Notices to Correspondents, Short Letters, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature* or initials, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

LOCAL REPORTS AND NEWS.—Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sending them to the Editor.

PUZZLED.—Syrupus calcei lactophosphatis of the new *Brit. Pharm.* is made by dissolving 25 parts of precipitated carbonate of calcium in 60 parts of lactic acid, adding 46 of concentrated phosphoric acid, orange flower water, sugar and water. This drug was greatly lauded upon its introduction for its virtue in phthisis. That it really possessed some value is more than likely, but modern open-air therapeutic methods have superseded all drug cures by a more rational comprehension of the etiology and pathology of tubercle.

THE EFFECT OF TITLES ON THE FEMALE MIND.

A CORRESPONDENT has related to us an amusing episode in connection with the recent bestowal of a title by Her Majesty on the head of a household. Some months before our *confre* could dub himself with the coveted prefix, his wife was apprised of the fact that the honour was shortly forthcoming, and her mind was immediately in a state of perturbation. The servants were summoned and put through their paces daily. They were instructed to practise addressing her as my lady this, my lady that; to answer the door to imaginary callers on her ladyship, and to the delivery of orders to tradesmen and others for lady so-and-so, until the entire household became one of expectant excitement. Meanwhile Dr. — was an amused spectator of feminine exultation.

DR. A. T. T. is thanked for his communication; the course pursued is quite the most dignified and proper under the circumstances.

FATALITIES FROM THE LOW FLASH OIL.

STATISTICS have been compiled by the editor of the *Star* news paper showing that sixty-three deaths have resulted from accidents with lamps in which the low flash oil has been used during the past half year against thirty-six in the corresponding period of 1898. What an outcry there would be had this serious loss of life resulted from an epidemic. But, say the authorities, if ignorant people will buy this common oil they must put up with the consequences.

DR. G. S.—There are entrance scholarships at most, if not all, medical schools, particulars whereof can be obtained by application to the Deans of the respective schools. In London most of these go to university students, no restriction being imposed in respect of the financial status of the candidate. While we quite agree that candidates for such scholarships ought to be required to sign a declaration of want of funds we know of no school where it is required. It, therefore, often happens that the rich man does not go empty away.

OBSERVER (Bradford).—We shall be pleased to receive any evidence you may be enabled to place at our disposal bearing on the case you refer to. We may mention incidentally that it is likely to be threshed out in the Law Courts, but we trust, not at our expense.

DR. R. J. L.—Communication to hand as we were at press.

MR. HY. KNIGHT.—Thanks, but scarcely suitable.

M.D. EDIN.—The work referred to has, we understand, been out of print for some time but a new edition is promised shortly.

Meetings of the Societies and Lectures.

WEDNESDAY, JULY 5TH.

OBSTETRICAL SOCIETY OF LONDON.—8 p.m. Specimens will be shown by Dr. Lewers, Dr. Lediard, and Mr. Gifford (introduced by Mr. Targett). Demonstration.—Prof. A. Thomson: On the Sexual Differences of the Fetal Pelvis. Papers.—Dr. Lewers: A Case of Persistent Mento-posterior Position of the Face in which the Child was delivered Alive by the Axis-traction Forcep. —Dr. Savory: Notes on a Case of Puerperal Eclampsia.

FRIDAY, JULY 7TH.

Vacancies.

Belfast District Asylum.—Locum Tenens Assistant Medical Officer for a few months. Salary, £3 3s. per week, with residence and attendance.

Berrywood Asylum, Northampton.—Assistant Medical Officer. Salary commencing at £150, with board, lodging, washing, and attendance.

Borough Asylum, Portsmouth.—Junior Assistant Medical Officer. Salary £100, with board, lodging, and washing.

County Asylum, Gloucester.—Third Assistant Medical Officer, unmarried. Salary £105 per annum, with board (no stimulants), lodgings, and washing.

County Asylum, Prestwich, Manchester.—Junior Assistant Medical Officer, unmarried. Salary commencing at £125 per annum, with apartments, board, attendance, and washing.

Essex and Colchester Hospital, Colchester.—House Surgeon. Salary £100 per annum, with board, washing, and residence.

Fisherton Asylum.—Assistant Medical Officer. Salary commencing at £120 per annum, with board, lodging, and washing. Apply to Dr. Finch, The Asylum, Salisbury.

Manchester Royal Infirmary.—Resident Surgical Officer for twelve months, unmarried. Salary £150 per annum, with board and residence.

Staffordshire General Infirmary, Stafford.—House Surgeon for two years. Salary £100 per annum, with board, lodging, and washing. Also Assistant House Surgeon. Salary £50 per annum, with board, lodging, and washing.

Surrey County Asylum, Brookwood, near Woking.—Medical Officer for about four months. Salary at the rate of three guineas per week, with apartments and all found.

Appointments.

BERRILL, A., L.R.C.P.Lond., M.R.C.S., Medical Officer for the Woodford Sanitary District of the West Ham Union.

BYFORD, W. F., M.R.C.S., L.R.C.P.Lond., Medical Officer and Public Vaccinator for the No. 1 Sanitary District of the Ruthin Union.

COLES, CHARLES, M.D., D.P.H.Lond., L.R.C.P., Medical Officer of Health to the Leicestershire and Rutland Combined Districts.

GRIFFITH, A. H., M.D.Aberd., F.R.C.S.Edin., Honorary Ophthalmic Surgeon to the Royal Infirmary, Manchester.

KNAGGS, E. L., M.D.Camb., F.R.C.S., Hon. Demonstrator of Surgical Pathology by the Council of the Yorkshire College.

LAWRENCE, G., M.R.C.S., Medical Officer to the Chepstow Work-house.

LEAF, CECIL H., M.A., M.B.Cantab., F.R.C.S., Surgeon to the Out-patients at the Gordon Hospital for Diseases of the Rectum, London.

MACVICKER, C. G., B.A., M.B.Irel., Medical Officer and Public Vaccinator for the Fourth Sanitary District of the Wel's Union.

MARSH, J. H., L.R.C.P.Lond., M.R.C.S., Medical Officer of Health, Macclesfield.

MEACHEN, G. N., L.R.C.P.Lond., M.R.C.S., Assistant House Surgeon to Guy's Hospital, London.

PITT-TAYLOR, F. S., M.B., Ch.B.Vict., Assistant Medical Officer to the Mill Road Infirmary, Liverpool.

REYNOLDS, E. S., M.D., F.R.C.P.Lond., Honorary Assistant Physician to the Royal Infirmary, Manchester.

SINCLAIR, A. M., M.B., C.M.Aberd., Honorary Medical Officer for the Burnley Victoria Hospital.

Births.

CARR.—On June 30th, at 19 Cavendish Place, W., the wife of J. Walter Carr, M.D., of a daughter.

DALTON.—On June 28th, at Cranmer House, Cambridge, the wife of J. H. C. Dalton, M.D., of a son.

GOURLAY.—On June 30th, at Faringcote, Guildford, the wife of F. Thornbrough Gourlay, of a son.

NEWINGTON.—On June 27th at The Grange, Edenbridge, the wife of Chas. W. Newington, M.R.C.S., L.R.C.P., of a son.

WALTER.—On June 25th at Lytham Road, Blackpool, the wife of R. A. Walter, M.R.C.S., L.R.C.P., of a son.

Marriages.

AUDEN-BICKNELL.—On June 27th, at All Saints' Church, Notting Hill, W., George Augustus Auden, M.A., M.B., B.C.Cantab., of Bootham, York, to Constance Rosalie, daughter of the late Rev. B. H. Bicknell, M.A., Vicar of Wroxham, Norfolk.

BOWER-WHITLEY.—On June 27th, at the parish church, Stretton, near Warrington, Harry Edward Bower, M.B., of View Field, Stretton, to May, eldest surviving daughter of Charles Thomas Whitley, of Wallspit House, Stretton.

SARJEANT-KEKWICK.—On June 28th, at St. Mary's Church, Islington, John Frederick Sarjeant, L.B.C.P., M.R.C.S., eldest son of John W. Sarjeant, of Wellington, to Jane Eleanor, elder daughter of the late James Watson Kekwick, of Carlisle.

Deaths.

HUGHES.—On June 24th, Philip Vernon Hughes, M.R.C.S., L.R.C.P., eldest son of the late Philip Hughes, aged 28.

NORMAN.—On June 29th, at 21 Sussex Gardens, Hyde Park, London, Julia Claudine, widow of William Alford Norman, M.B., F.R.C.S.

SWABY-SMITH.—On July 2nd, at 124 Mill Lane, Hampstead, C. Swaby-Smith, M.R.C.P.Edin., M.R.C.S., LL.A., aged 64.

DECIDUOMA MALIGNUM?

A CRITICAL REVIEW FROM A CASE SUCCESSFULLY TREATED BY

VAGINAL HYSTERECTOMY. (a)

F. W. N. HAULTAIN, M.D., F.R.C.P.E.,

Lecturer in Obstetrics, Edinburgh School of Medicine.

TEN years ago, Sänger described under the name of Deciduoma Malignum, a new growth of the uterus, which he considered owed its origin to an immediately pre-existing pregnancy. Since then a considerable number of cases have been recorded.

The condition in question is of much importance clinically, and interesting pathologically. From a clinical aspect its importance lies chiefly in its malignancy and comparative rarity. When untreated by radical means, death in the majority of instances occurs within 6 months of the confinement, although in a few instances it seems to run a more chronic course. The causes of death are hæmorrhage, septicæmia, and pulmonary embolism from metastases, the last being most common.

Its supposed rarity is questionable. Already I have been able to collect 90 cases published; of these the vast majority are German. In England, curiously enough, but six cases have been described, and in Scotland only one. This infrequency in Britain is probably to be explained through a want of appreciation of the true character of the growth, many being considered ordinary carcinomata and sarcomata, and claiming no particular attention. This contention is supported by the fact that up to 1896 when the condition was comparatively unknown, only 26 cases could be found in the literature, while now, three years later, 90 cases have been recorded.

Though important clinically, it is doubtless from a pathological standpoint this so-called deciduoma is of paramount interest; indeed, it is questionable if any pathological subject within the last five years has comparatively had bestowed upon it more investigation or given rise to such diversity of opinion as regards its structure, origin, and designation. Observers may be divided into two primary groups. 1. Those who believe the growth to be an ordinary sarcoma having no connection with pregnancy, and 2. Those who consider it to owe its origin to an immediately pre-existing gestation. The first group embraces practically the opinion of all the British investigators, with the exception of Teacher. (b) While the second group only agree to differ in detail. Thus we have Sänger suggesting its decidual origin, Gottshalk maintaining it arises from the stroma of the chorionic villi, and Williams, from the syncytium alone; while Marchand, Gebhard, Teacher, and many others assert its structure embraces both the epithelial layers of the chorionic villi. To still further complicate matters, the question of the origin of the syncytium forms a point of debate as to whether the tumour is maternal, foetal, or both.

(a) Paper read and Demonstration given before the British Gynaecological Society, June 8th, 1899. For discussion see page 6, No. for July 5, 1899.

(b) "Pathological Journal," 1899.

Before venturing any assertion on this much-vexed question, I will take the opportunity of describing in detail a case which I had the good fortune to have placed under my care.

On October 18th I was asked by Dr. Thomson, of Musselburgh, to see with him a woman who was suffering from copious uterine hæmorrhage, and who gave the following history:—

On September 10th, after a period of amenorrhœa which had lasted for ten weeks, she was seized with a sudden and profuse hæmorrhage for which the vagina was plugged. As the bleeding continued and the uterus was found to be enlarged it was decided to evacuate its contents. After the introduction of a bougie into the uterus and tight vaginal plugging, she spontaneously expelled a myxomatous mole. Her recovery seemed in every way normal and satisfactory; but on October 6th slight bleeding reappeared, and after a few days there was expelled a large fibrinous mass, not unlike a carneous mole. During and after its expulsion the bleeding was excessive and reduced the patient to a state of profound anæmia. At this time I now saw the patient. On local examination the uterus felt enlarged and soft, and the cervix sufficiently patulous to admit the finger for a considerable distance, though not entirely to the fundus.

FIG. 1.—Uterine scrapings which show (F) nucleated protoplasmic masses and large actively proliferating malignant cells. (d) Fibrin.

Being of opinion I had to deal with subinvolution due to retention of gestation products, I curetted the uterus, and was at the time struck with the free nature of the bleeding which occurred, and which could only be stopped by very thorough intra-uterine plugging. As I was suspicious on this account of some malignant growth, I preserved the scrapings, and carefully examined them microscopically (Fig. 1). They showed the characteristic multi-nucleated protoplasmic masses and large nucleated cells described as occurring in deciduoma malignum, and, I therefore advised immediate

hysterectomy. As Dr. Thomson informed me, however, that the patient was well, the bleeding entirely having ceased, and that she and her friends would not hear of such radical methods being adopted, I reluctantly abandoned the idea of immediate operation, but strongly insisted that in the event of hæmorrhage recurring, such should be carried out without delay.

On November 21st, 1898, more than a month after curetting, a sudden profuse hæmorrhage occurred, and the patient was sent to my hospital. On arrival, after a journey of some miles in an ambulance, during which she was bleeding profusely, I found her in an extremely exhausted and exsanguine state. So much so indeed that I felt immediate operation to be unsafe. As I was aware of the terribly malignant nature of the disease, I hesitated to delay operation long, and on November 24th performed vaginal hysterectomy, which was easily and rapidly accomplished. The ovaries and tubes were not removed. Her recovery was uninterrupted, and she is now in evident health, although eight months have passed.

On examination of the uterus there was found on section a small growth (walnut) springing from the upper part of the anterior uterine wall, sessile in nature and bulging into the uterine cavity. It was covered (with the exception of a small portion) by apparently smooth healthy mucosa, and from the uncovered portion there protruded a mass of blood clot. The rest of the uterine cavity was lined by an apparently healthy mucosa.

On a complete section of the tumour the portion which bulged into the uterine cavity appeared to be composed mainly of fibrinous material, which indefinitely and irregularly gave way to a grey, apparently cellular layer, which in turn encroached into the substance of the uterine wall in an equally indefinite and irregular manner by means of prolongations along the blood sinuses. This infiltration was by no means extensive, and appeared to leave a large area of healthy uterine tissue between the growth and the serous surface of the uterus.

FIG. 1A.—(F) Necrotic are. (C) Cellular area of activity. (V) Villi.

Microscopically: The structure of the growth is seen to be composed of blood clot, two varieties of cellular elements and chorionic villi (Figs. 2, 3, 4).

The cellular elements are of two types, (1) large polyhedral cells, which stained lightly, and whose large nuclei show a wide intranuclear network, and (2) multinucleated deeply staining protoplasmic

masses of all varieties of shape, whose nuclei are extremely rich in chromatin and show no wide intranuclear network as in the other cells. Both varieties of elements, however, show a marked tendency to retraction of their protoplasm and vacuolation. Mitotic figures were frequently observed in the individual cells, but nowhere in the protoplasmic masses. The relationship of these two types of cells varies greatly; in some instances it appeared as if groups of individual cells were confined in alveoli formed by processes of nucleated protoplasm. This is most apparent when in close relationship with the chorionic villi. As one proceeds further from the villi the cells and protoplasmic masses are arranged indefinitely. The individual cells, in some places, are much in excess of the protoplasmic masses, while in others the latter only

FIG. 5.—Branching multinucleated protoplasmic processes in free blood spaces.

are to be distinguished (Fig. 5). Nowhere is there evidence of intercellular substance, or blood-vessels, although free blood is intimately mixed with the cells, and is also found in the vacuoles in their substance.

Extending into the muscle can be seen clumps of both types of cells, apparently following the perivascular lymph spaces, while throughout, individual cells may be seen finding their way indiscriminately, with a special tendency to penetrate the

venous sinuses and engraft themselves on the interior of their walls, where they continue to proliferate.

The chorionic villi in some instances show degeneration of their stroma, but others present an almost normal appearance. In all, however, there is evidence of great activity in their epithelial coverings. On section of the tumour three areas might be microscopically described: 1st, the submucous or peripheral area, which forms the main bulk of the tumour mass, and is necrotic in character, composed of fibrin and cellular elements in all stages of degeneration; 2nd, a cellular area or tumour proper, which is composed entirely of actively proliferating cellular elements and chorionic villi mixed with free uncoagulated blood; while, 3rd, we have the area of infiltration, in which may be seen cells and protoplasmic masses isolated, and in groups insinuating themselves into the blood channels (Fig. 7), and surrounded by the degenerating muscular fibres of the uterine wall. From what has been described, therefore, it would appear as if the rôle of the cellular elements composing the growth was to penetrate the blood channels, in which, so long as the blood circulation con-

FIG. 7.—Area of invasion. Both varieties of malignant elements (C) in small vessel and surrounding tissues.

tinued, they maintained their vitality and proliferated rapidly, but when coagulation and extravasation of the blood took place, they rapidly degenerated. It also appears as if the protoplasmic processes and masses had an amoeboid character not only in their power of movement, but more especially in the phagocytic action on surrounding tissues; everywhere they were surrounded by a free blood space, and in the interior of many of the masses could be seen degenerated blood and debris in the process of absorption. From this action their power of rapid infiltration is very great.

In seeking for an origin of this curious variety of growth, and at the same time recognising the fact as pointed out by Sanger, that they always arise after an immediately pre-existing pregnancy, one naturally turns for a physiological prototype to the placenta.

Here, as is well known, in the early weeks we have extreme activity in the epithelial coverings of the villi, especially at their tips, when they come in contact with the decidua (Figs. 10, 11). By means of this epithelial proliferation more villi are formed, and at the same time through the phagocytic action of these epithelial layers, maternal blood-vessels are opened into and an actual encroachment made into the decidua itself. In due course, however (accord-

FIG. 10.—Normal placenta, sixth week. (CD) Chorio-decidual space into which (A) vessel opens by dilatation, see endothelial lining. (V) Villi with intense proliferation of Langhan's cells. (D) Decidua. (L) Protoplasmic multinucleated masses, from specimen of Dr. Gulland's.

FIG. 11.—Normal placenta, sixth week $\times 200$. (V) Tip of villus. (D) Decidua. (L) Proliferating cells of Langhan's layer. (S) Multinucleated protoplasmic masses. (CD) Chorio-decidual space lined by endothelium.

ing to Fothergill), the decidual cells, which are also phagocytic in action, overcome the ingress of the chorio-epithelium, destroy it entirely when in contact with it, and thus prevent infiltration of the uterine wall by villi. In other words the decidua may be looked upon as the first line of maternal defence against the inroads of parasitic villi. On microscopic examination the villi are found to be covered by two layers of epithelium, an inner composed of individual cells (Langhan's layer) and an outer of nucleated protoplasm not differentiated into cells (syncytium), and on comparing these layers with the cells of the tumour in question one is struck by the similarity. If further proof be wanting of their identity one need only turn to the villi found in the tumour, which, as shown (Fig. 7), display an intense activity in both layers of epithelium. The individual cells of Langhan's layer, dividing and multiplying in all manners and ways, whilst the syncytium can be seen every-

where throwing out large complex processes of a similar structure to itself. It cannot but be considered from the appearances thus presented, that the origin of at least this tumour has been from the epithelial layer of the villi.

In further investigating the origin of the so-called deciduomata in general, one must naturally turn to an examination of the structure of myxomatous chorion, a condition with which it seems to be closely allied, as shown by the fact that of the 91 cases of deciduoma recorded, 49 followed the expulsion of this variety of mole. And if it be kept in mind that myxoma of the chorion is in itself an infrequent condition, occurring only once in 1,800 pregnancies, *a priori*, it is to be expected that a connecting link may be found between the normal villus of the young placenta and the growth in question. In this reasoning one is not disappointed, for microscopic examination of so-called myxomatous villi demonstrates this abnormality to be due to an intense activity in the syncytium and to a lesser extent of Langhan's layer, by which rapid proliferation and the formation of new villi is accounted for. (Fig. 12). It will also be noted that there is an extraordinary vacuolation of the syncytium. As one

FIG. 12.—Myxoma of chorion. Transverse section through small villus $\times 200$ showing (S) retracted stroma of villus. (VP) Enormous hypertrophy and vacuolation of syncytium. (C) Proliferation of Langhan's layer.

would naturally expect, a result of this excessive activity in the epithelial layers of the villi is an increased aggressive action of the villi on the surrounding decidua and a deeper penetration into its substance. In some instances, as is well known, this may be so extreme that the villi not only travel through the entire thickness of the decidua, but penetrate the muscular wall of the uterus, and give rise to spontaneous rupture or peritonitis; or in other cases pass into the blood stream and give rise to metastases and pulmonary embolism.

It is no mere fancy, then, to argue that, under certain conditions, villi with actively proliferating epithelium may penetrate the muscle wall of the uterus, and in this situation by continued activity of their epithelial coverings, give rise to the new growth we are now considering. This condition is certainly more likely to result from a myxomatous mole pregnancy where the villi are specially active, and more prone to overcome the resistance of a normal decidua, but it is also possible through a weakness in the decidual defence, that the villi of a normal pregnancy, may reach the muscular wall of the uterus and there continue in a state of activity, and give rise to an epithelial growth. The chain of evidence

in favour of this new growth being of epithelial origin has, to my mind, no weak link; the structural appearances, the physiological prototype of the young villus, and the interesting association with myxoma of the chorion which it closely resembles anatomically, physiologically, and pathologically, all serve to prove that the growth is of epithelial origin, at least, so far as concerns the case under our immediate notice.

(To be concluded in our next.)

THE SEXUAL DIFFERENCES OF THE FŒTAL PELVIS. (a)

By ARTHUR THOMSON, M.A. Oxon, M.B. Ed.,

Professor of Human Anatomy in the University of Oxford; Lecturer on Anatomy in the Government School of Art, South Kensington.

AFTER demonstration by the aid of numerous diagrams and lantern slides of the sexual differences in the conformation of male and female pelvises during foetal life as resulting from his researches the author commented on the absence of any reference to the subject in most anatomical works, and he pointed out that to Fehling belongs the credit of discovering that the differences in form and appearance are such as to enable the observer to distinguish between the pelvis of the male and female as early as the third month of foetal life. He referred to the statement which still finds currency that no such differences obtain until the period of puberty, and he discussed the explanations that had been offered of the causation of the differences at that period. He alluded in particular to the views held by Matthews Duncan, who suggested that the changes were less marked in the male pelvis, in which the bones were thicker, stronger, and stouter, and more early consolidated with each other, these conditions being at once the signs and causes of the peculiarities of a masculine pelvis. The author's object was to insist upon the fact that at a comparatively early period in the development of the foetus the sexual differences are as pronounced and characteristic as they are in the adult. He showed a number of pelvises taken from foetuses which had been previously hardened in spirit which had been preserved as moist specimens, this moist condition being an important point to bear in mind in drawing deductions. He noted that in respect of the proportions of the pelvis as a whole the breadth-height index is high—viz., 85·6 for the females and 82·4 for the males, in other words the height of the foetal pelvis is great in proportion to its width. It follows that during the growth of the pelvis from the foetal to the adult form there is a greater proportionate growth in width than in height. In the foetal condition, however, the breadth-height index in the female is higher (85·6) than in the male (82·4), the converse whereof holds good in the adult, so that the female pelvis during growth appears to increase in size more rapidly in width than in height, a circumstance no doubt associated with the peculiarity in the form and size of the hinder portion of the ileum. In the foetus the splay of the lateral walls of the pelvis is greater in the male than in the female, and it is noteworthy that this difference is characteristic of the different sexes in the adult. This difference in the splay of the pelvic sides reacts on the proportions of the true and false pelvis, so that in the female the lower segment bears a larger proportion to the upper segment; while in the male, owing to the greater

splay of the pelvic wall as a whole, the proportion of the lower segment to the upper is much less than in the female. The author attached considerable importance to the proportion of the width of the ileum to the total pelvic height. His results show that during growth the increase in width of the ileum is proportionately greater than the increase in height of the innominate bone. It is, however, in the true pelvis that the appearances characteristic of sex are principally met with, and they are as well marked in the foetus as in the adult. The form of the inlet in the male is described as caudate as contrasted with the more uniformly oval elliptical or reniform aperture in the female. The proportion which the sacrum bears to the pelvic inlet is of some importance, and as a matter of fact the foetal sacrum is larger in proportion to its surroundings than in the adult. He finds, too, that the females even in the foetal condition possess a sacrum which bears a relatively larger proportion to the maximum pelvic width in the male such as maintains in the adult. He showed that the sacrum in the foetus exceeds the width of the pelvic inlet, and he pointed out that the increase in the size of the diameters of the inlet of the pelvis is due in large measure to the growth and development of that part of the iliac bone which overtops and forms the upper boundary of the great sacro-sciatic notch. He pointed out that the narrowness of the foetal sacrum so often alluded to in works of reference has no existence in fact. He notes in the male foetus a higher sacral index than in the female, indicating a proportionately greater width of sacrum in that sex, the converse of what obtains in the adult. Passing on to the true pelvis the author noted that apart from the differences in the outline of the inlet the walls of the true pelvis in the male encroach much more on the cavity owing to their greater obliquity. The relative width between the ischial spines is greater in the adult than in the foetus attributable to the fact that, unlike most of the other spinous prominences on the innominate bone the ischial spines are not provided with secondary epiphyses from which it may be assumed that their growth ceases at a much earlier period with the consequent effect of proportionately increasing the width between them in the adult. The author drew attention to the marked difference between the angle of the pubic arch in the male and female foetuses, differences which can easily be recognised without the aid of instruments when the specimens are placed side by side. It is evident, indeed, that although there is an increase in the angle with the growth of the pelvis, the sexual difference is maintained throughout. Another feature in which the adult female pelvis differs from the male is the form and size of the great sacro-sciatic notch. This in the female is usually wider and shallower than in the male. If the forms of the male and female adult innominate bone be compared, it will be seen that in the female the width of the posterior part of the ilium is greater than in the male, and this difference exists even during foetal life. From a consideration of the facts already stated, it follows that in many of its forms and proportions the foetal pelvis conforms very closely to the adult. The greatest difference is met with in the innominate indices and in the proportion of iliac width to pelvic height. To sum up, it appears from a consideration of the foregoing facts that during foetal life the essentially sexual characters are as well defined as in the adult forms, and that any differences that occur during growth between the adult and foetal forms, due it may be to the influence of pressure or muscular traction, affect both sexes alike, and that such influences are in no wise accountable, as has been maintained, for the characteristic features of the pelvises of females as contrasted with the male.

(a) Paper read at the meeting of the Obstetrical Society, July 5th, 1899. The discussion will be found on page 35.

ON A CASE OF TUBERCULOUS OVARY REMOVED BY ABDOMINAL SECTION. (a)

By W. J. SMYLY, F.R.C.P., M.D., T.C.D.,

Gynaecologist to the Adelaide Hospital; formerly Master of the Rotunda Hospital, Dublin, &c.

UNTIL quite recently such a condition was unknown, but Martin, in his recent work on diseases of the ovaries, states that 184 cases have been recorded in recent years, so that the disease is not so rare as had been supposed. As a primary affection, however, it is extremely rare, three cases only having been recorded by Edmonds, Jacobs, and v. Franke, but even these are doubtful. The patient was *æt.* 28, and had been married two years. She enjoyed good health until shortly before marriage, when she had influenza, from which, however, she completely recovered. About Christmas, 1897, she began to feel ill, and had gradually got worse. I first saw her in April, 1899. She complained of always feeling tired, and seldom left her bed before midday, had profuse night sweats, and had steadily lost weight—18 lbs. in the last twelve months. She was greatly emaciated, had the appearance of a person in advanced phthisis, and had not menstruated for seven months. She had no cough, nor any physical signs of pulmonary disease. The abdomen was somewhat distended, and a small tumour could be detected in the left inguinal region, which, upon bimanual examination, proved to be the uterine adnexa of that side. The uterus and right appendages appeared to be normal. Tuberculous disease of left uterine adnexa was diagnosed, probably involving the tube, and associated with tuberculous peritonitis.

Operation.—On opening the abdomen no general tuberculous disease was found. There were, however, dense pelvic adhesions, but no visible tubercles. Both tubes were found diseased, the right being about as thick as an ordinary pencil; the left, somewhat larger, lying upon an ill-defined mass about the size of an orange. When freeing the right tube it burst, and some pus escaped, but it was removed, with the accompanying ovary, without difficulty. The tumour on the left side had developed in the mesorectum, which was intimately connected with it, passing over it from left to right, and then down behind it. The peritoneum was opened in front of the rectum, and about a quarter of an inch from it, but in attempting to detach the latter, though the greatest care and gentleness were used, the finger penetrated the gut. Keeping the finger ends in contact with the tumour, it was enucleated without difficulty, brought up out of the pelvis, and removed with the tube in the ordinary manner. Upon examining the cavity left, however, it was discovered that the entire anterior wall of the rectum was wanting as far down as the reflexion of the peritoneum. After consultation with Dr. Gordon, who assisted at the operation, it was decided that an ordinary enterorrhaphy offered small prospect of success, not only because of the extent of the injury, but also because of the condition of the surrounding structures. It was, therefore, determined to resect the injured portion of bowel, and about two inches having been removed, two ligatures were inserted, one on either side of the lower end of the upper portion of the bowel, and by means of these it was drawn down into the lower portion, and secured there by a double row of sutures. Having sponged out the pelvic cavity, and packed the sutured portion around with iodoform gauze, the ends were brought out at the lower angle of the abdominal incision, the rest of which was closed in the usual manner.

(a) Read before the Royal Academy of Medicine in Ireland, May 26th, 1899.

The patient suffered severely from shock, but improved somewhat towards evening. Next day, however, she was not so well; the pulse was very rapid and weak, and the surface bedewed with cold, clammy sweat. During the night vomiting set in with violent abdominal pains, and Dr. Smyly was summoned to her early in the morning. She had then violent abdominal pains, with evident peristaltic movements of the intestines, but no flatus had escaped. There was constant vomiting, no radial pulse could be felt, and her arms were cold up to the elbows. An endeavour to reach the constriction per anum failed. Dr. Gordon saw her in consultation at 9 a.m., but as the wound presented an unhealthy appearance, and could not be used to form an artificial anus, and as it was evident that to have opened the abdomen in another position it would have proved immediately fatal, it was decided that nothing further could be attempted. During the day she gradually became worse, and the vomit assumed a faecal character. Shortly after midnight, however she took a turn for the better, passed flatus, and shortly after a faecal motion; pains and vomiting ceased, and she took and retained nourishment. Since then she has steadily improved, takes her food well, and is putting on flesh. A considerable but steadily decreasing quantity of faeces, however, escapes from the abdominal wound. The specimen under the microscope shows giant cells and caseation.

A COUNTRY HERBALIST'S CURE FOR THE "KING'S EVIL." (a)

By JOHN KNOTT, M.A., M.D., and Dip. Stat. Med. (Univ. Dub.); M.R.C.P.I.; M.R.I.A.; &c., &c.

(Continued from page 4.)

THE herb which forms the second ingredient of our remedy is thus described by the same author:—

"ULMARIA SIVE REGINA PRATI.—Medowsweete or Medesweete. Of this herb there are two sorts, the one familiar to our country, the other a stranger to us, and only entertained of a few, and those the lovers of rare plants.

"1. ULMARIA VULGARIS.—Common Mede or Medowsweete. The stalks of this Medesweete are reddish and easie to breake, rising to be three foot high, and sometimes to be four or five, having at the joynts thereof large winged leaves, standing one above another at distances, which are made of many somewhat broad leaves, set on each side of a middle ribbe, being hard, rough or ragged, crumpled much like to Elme leaves, whereof it tooke the name, but having also some smaller leaves with them, even as Agrimony hath, somewhat deeply fluted about the edges, of a sad greene colour on the upper side, and grayish underneath; of a pretty sharpe sent and taste, very like unto Burnet, and will no lesse give a fine relish to a cup of claret wine if a leafe be put therein then Burnet; at the toppes of the stalkes and branches stand many tufts of small white flowers thrust thicke together, which smell much sweeter than the leaves; and in their places being fallen, come croked and cornered seede; the roote is somewhat woody and blackish on the outside, and brownish within, within divers greater strings and lesser fibres set thereat, of a strong sent, but nothing so pleasant as the flowers or leaves, and perisheth not, but abideth many years, shooting forth anew every spring.

"2. ULMARIA MAJOR SIVE ALTERA.—The greater Medesweete. This Medesweete groweth higher than the former, with longer winged leaves set one above

(a) An abstract of this paper was read in the Medical Section of the Royal Academy of Medicine in Ireland on Nov. 18th, 1898.

another upon the crested brownish stalkes, having long footstalkes upon them, each being divided usually into three parts, the two lowest one against another, and every part also consisting of three to five smaller leaves than the other. Separate each from the other, being hard crumpled, and finely dented about the edges: at the tops of the stalkes grow the flowers in longer spikes, more sparsely and not so thick thrust together, turning downe their heads which are white like the former, and smelling very sweete also, more nearly resembling a goat's beard, whereof some have given it the name than the other; the root is more woody, with many blackish strings which smell strong, and taste somewhat harshly; the stalks and leaves dye wholly downe every yeare, and rise againe in the spring.

"THE PLACE.—The first growth in moyst Meddowes that lye much wet, or neare the courses of water, and the later is found also in shadowie woods, and places very often.

"THE TIME.—They are found in some place or other, all the three Summer moneths, that is, June, July, and August, and their seede is ripe quickly after.

"THE NAMES.—They are not found mentioned by any of the ancient Greekes or Latines, only some think it may bee referred to *Rodora* of Pliny. It is called by the later writers *Ulmaria*, a *foliorum Ulmi* similitudine, of the likeness of Elme leaves, of *Dodonæus Regina prati*, and *Barba* and *Barbula Capræ*, or *Barba Caprina* of *Tragus*, and by him thought also that it might be *Picnocomon* of *Dioscorides*, as *Gesner* in *hortis* and *Lonicerus* doe. *Fuschius* calleth it *Barba capri*, and *Lobel Barbi capra*. *Cordus Medesusium*, from the Germane word *Medesusas*, that is *Meddowsweete*. Some, as *Lugdunensis* saith, tooke the later to be *Melandrium Plinii*, and some also call it *Drymopogon*; *Anguillara* calleth them *Potentilla Major Prima* and *Secunda*, and *Thalius* the greater sort *Argentina Major*. *Anguillaro* saith the Italians call it *Christoforiana*, the French call it *Barbe de Cheurre*, and *Roine des Preis* the Germanes *Geisart*, and the greater *Wielde Geishart*; and *Camerariss* saith *Wormkraut*, because, as he saith, the roote is often found, as it were, eaten by Wormes; but it is more likely for that it helpeth horses of the *Bottes*, and Wormes, and so he saith the country people used it; the Dutch *Riemette*, and as *Lobel* saith *Gheytenbladt*, and *Cameraridt*, in English *Medesweete* or *Meddowsweete*, and *Queene* of the fields or *Meddowes*.

"THE VIRTUES.—Being neare a little in taste and smell with *Burnet*, they are most likely to bee neare of the same facultie, yet *Tragus* accounteth them more hot and dry; they are also used in the same manner, and with same purposes, to stay all manner of fluxes, bleedings, and vomitings, and women's courses, as also their whites; it is said to alter and take away the fits of quartaine ague, and to make a merry heart, for which purpose some use the flowers, and some the leaves; it helpeth also speedily those that are troubled with the Collick, being boyled in wine and with a little honey taken warme, it doth open the belly; but boyled in red wine and drunke, it stayeth the flux of the belly, &c., it helpeth the *Bottes* in horses as you heard before; being outwardly applyed it healeth old Vicers, that are cancerous or eating, and hollow or fistulous, which many have used and much commended; as also for the sores in the mouth, and secret parts: the leaves when they are full growne being layd upon the skinne, will after a small time raise blisters thereon *Tragus* saith: the water thereof helpeth the heate and inflammation in the eyes; the seede as *Camerarius* saith being taken, causeth paines in the head; and because both flowers

and herbes are of so pleasing a sweete sent, many do much delight therein, to have it layd in their Chambers, Parlours, &c., and *Queene Elizabeth* of famous memory did more desire it than any other sweet herbe to strew her Chambers withall: a leafe or two herbe layd in a cup of wine, will give as quick and as fine a relish thereto, as *Burnet* will, as I sayd before."

In *Salmon's Herbal*, published in London in the year 1710. elaborate attention is paid to the uses and preparations of *Wood Sorrel*, which was then, very evidently, at the zenith of its fame.

"OF SORREL WOOD, OR SOUR TREFOIL.

"THE NAMES.—It is called in Greek *ὄξυς*, and in Latine, "*Oxys*, *Oxys Pliniana*," Lib. 27, cap. 12. *Oxytriphylum Tragi* and *Lacune* (but *Oxytriphylum* is a more proper name for the sharp pointed Trefoil) *Trifolium Acetosum*, *Panis Cuculi* (*Cuculow's* meat) also *Alleluja* (because it was in flower, when in ancient times *Alleluja* was wont to be Sung in Churches): and *Luluja* (a corrupted word from *Juliola*, as in *Calabria* in the kingdom of *Naples* it is called), in English, *Wood Sorrel* or *Sour Trefoil*.

"THE KINDS.—The chief sorts common with us are 1. *Oxys Plinii*, *Alleluja*, *Lujula*, *Oxys alba Communis*, *Trifolium Acetosum Vulgare*; Our Common *Wood Sorrel*. 2. *Oxys flore Luteo Clusii*, *Oxys-lutea corniculata repens Lobelii*, *Trifolium acetosum corniculatum Bauhini*, *Oxys Americana*, *Yellow Flower'd Wood Sorrel*.

"THE DESCRIPTIONS.

"3. The first, or common *Wood Sorrel*. Its Roots are nothing but Strings fastned to the end of a small long Piece, all of them being of a yellowish color, not perishing every year, but abiding with some Leaves thereon in the Winter. It grows low upon the ground without any Stalk, rising from it, having a number of Leaves coming from the Root, which Leaves are made of three parts like a Trefoil, but broad at the ends and cut or dented in their middle (almost in form of a Heart) of a faint yellowish green color, each one standing on a long Footstalk, which at their first coming up are close folded together to the Stalk, but opening themselves afterwards, and are of a pleasing sour relish, more grateful and pleasing than any of the former Sorrels, and yielding a juice, which will turn red when it is clarified, and make a most delicate clear Syrup. Among these Leaves, rise up divers slender weak Footstalks, not growing higher than them, each one having a Flower at its Top, consisting of five small and pointed Leaves, Star fashion, of a white color in most places, or in some dasht over with a small show of blush, and in some (but on the backside only) of some other colors. The flowers being past, then follow small round heads, with small yellowish Seed in them.

"4. *Gerard* describes it thus:—Its root is very threddey, and of a reddish color. It is a kind of three-leav'd grass, and is a low and humble herb, without stalk: the leaves immediately rising from the Root upon short stems: at their first coming forth folded together, but afterwards spreading themselves abroad, of a fair, light green color, in number three, like the rest of the Trefoils, but that each leaf has a deep cleft in the middle. Among these leaves come up small and weak tender stems, such as the leaves do grow on, which bear small star-like flowers of a white color, with some brightness of carnation dasht over the same. The flower consists of five small leaves, after which come little round knaps or husks, full of yellowish seed. The whole herb is in taste like *Sorrel*, but much sharper and quicker, and makes better green sauce than any of the other Sorrels. *Johnson* in *Gerard* says, that he had some of these Plants sent him, with very fair red flowers, which were gathered in a Wood of *Sir Thomas Walsingham's*

called Stockwell Wood, at Chissel-hurst, in Kent, and in a little round Wood there adjoining.

"5. THE SECOND OR YELLOW FLOWER'D WOOD SORREL.—Its Root is a brush of Fibres, and abides all Winter without perishing, if it be not too Violent or Cold, the Extremity making them rot and perish, so that the plant must be raised from Seed sown again. It shoots forth several slender, weak, reddish Stalks, trailing upon the ground, yet growing in a heap as it were, the Stalks take Root at the Joints as they lie, spread into many Branches, with many Leaves on them, standing simply one above another, and made of three leaves, cut in at the end like the former, but are much smaller, and of a Pale green Color; at the Joints with the Leaves come forth three or four small flowers together, at the end of a long Footstalk yet each separate from the other, consisting of small and pointed leaves like the former, but contained in smaller, and larger heads, like Cods or Horns, yet not Crooked but pointed small, which quickly fade away on being touched when they are ripe, and spring up again all about where it grew.

"6. THE PLACES.—The first grows very plentifully in many places in England, in woods and by wood-sides, where it may be moist, and shadowed from the Sun, also in other places not too open to the Sun-Beams, the Second grows in Spain, Italy and Sicily; but in a vast plenty in almost all our worne out Plantations of Maze, in South Carolina, and other places adjacent thereto, where I have gathered it many times: there is scarcely any Herb which grows in greater plenty in those Countrys than this.

"7. THE TIMES.—The first Flowers early in April and May, the other in June, July and August, and so continues in flower with the cold of Autumn causes it to perish, the seed ripening in the meantime.

"8. THE QUALITIES.—These are of the Temperature, and properties of Common Sorrel in the former Chapter; but more potent to all those purposes, and are special Alexipharmicks or Antidotes against the Plague, and all sorts of Pestilential, Malign, and Burning Fevers.

"9. THE SPECIFICATION.—Wood Sorrel resists Vomiting, strengthens the Stomach, hinders putrefaction of the Blood, quenches Thirst, provokes Appetite, and is effectual against the Plague, Spotted Fever, Calentures, and other like Malign diseases.

"10. THE PREPARATIONS.—You may make therefrom, 1. A Juice. 2. A Decoction or rather Infusion. 3. A Syrup. 4. A Conserve. 5. A Cataplasm. 6. A Distilled water.

"THE VIRTUES.

"11. THE JUICE.—It has all the before specified Virtues, cools Inflammations, takes away all præternatural heats, whether in the Stomach, Bowels, or habit of the Body; resists putridity, and is most singularly excellent against any Contagious Sickness or Pestilential Fever. Mixt with a fit quantity of double refined sugar, it makes most incomparable Green Sauce.

"12. THE DECOCTION OR INFUSION.—They have the Virtues of the Juice, but not so effectual, and may be given half a Pint at a Time: if they are made in Wine (whether White or Red), they will be so much the more effectual in some cases, more especially where no Fever is present.

"13. THE SYRUP.—It is effectual in the cases aforementioned, does exceedingly cool, and abort the heat of Fevers; and mixed with Juice, makes an excellent Gargarium for a sore Mouth and Throat, being gargled therewith and spit out, and then fresh taken in; it wonderfully helps a stinking foul Canker or Ulcer in those parts, and is singular good in Wounds made by Cut or Puncture, stopping their bleeding and causing them speedily to heal.

"14. THE CONSERVE.—It is cordial, refreshing in hot Fevers, stops Vomiting, and strengthens a weak Stomach, and is profitable against Catarrhs or hot defluxions of Rheums upon the Stomach and Lungs.

"15. THE CATAPLASM.—It is made either of the whole green Herb bruised: or made of the Herb, pushed between two Pewter Dishes, and brought to a Consistence with Crumbs of white Bread. It abates the heat of Inflammations and other hot Tumors, cures simple Contusions, being presently applied, viz., whilst they are recent; applied to simple green wounds also, it heals them in a short time, by stopping the Hæmorrhage and conglutinating their Lips.

"16.—THE DISTILLED WATER.—It has all the Virtues of the Juice and Decoction or Infusion, but very much weaker: It quenches thirst, and cools inward heats of the Stomach, Lungs, and Liver, being taken morning, noon, and night, half a Pint at a time, sweetned with the Syrup aforementioned; and so mixed it makes a good Gargarium for Sore and Cankerous Mouths and Throats."

And the same notable authority gives a correspondingly elaborate and appreciative account of the qualities, uses, and preparations of the second herb which enters into the composition of our cure.

(To be continued.)

Clinical Records.

COOMBE LYING-IN HOSPITAL, DUBLIN.

A Successful Case of Cæsarian Section.

Under the care of F. W. KIDD, B.A., M.D.,
Master of the Hospital.

THIS case presents many points of interest. The operation was not done for contracted pelvis, but for a large growth which sprang from the posterior portion of the cervix. When seen at first this tumour was drawn up to such an extent that it seemed possible to push up the cervix; however, this method proved quite ineffectual. Patient was æt. thirty-two, and was a primipara; she was visited at her own house on the 3rd December. The tumour was then diagnosed, and the patient was brought into hospital. A thorough examination was made, and as the patient had had labour pains it was determined to operate at 1 a.m. on the morning of Sunday, the 4th December. Every antiseptic precaution was taken, and on Dr. Stevens devolved the duty of attending to the child when born, I was assisted by Drs. Heuston, Cole-Baker, and Scully. Incision was about 2 ins. above and 4 ins. below umbilicus, placenta, which was huge (11 ins. by 7), was on anterior wall of uterus, and to right, and directly under incision in wall of uterus, so that it had to be dissected off towards left side for an inch or two. Then there was difficulty in getting at the lower extremities of child. Finally one was extracted before the other, with the result that the incision in uterine wall was ruptured at top end for a further two inches in an oblique direction. Membranes were unruptured at time of operation. The uterus did not immediately contract, and the bleeding was very considerable. Uterus was sutured with deep, strong silk sutures, going down to but not involving mucous membrane, with alternate superficial sutures of a finer silk drawing peritoneum well over line of incision, parietal peritoneum drawn together with continuous suture of fine silk, and abdominal incision closed with silk-worm gut sutures. Convalescence was somewhat protracted on account of an attack of bronchitis and the severe hæmorrhage; however, the temperature never reached 100 deg. F., and the patient made a remarkably good recovery. The child, which was a male, was born partly asphyxiated, but under the care of Dr. Stevens, who Schultzed him, he came to, but never cried lustily. He died on the third day; had had a slight convulsion the preceding day; his muscles had seemed continually to be tense, and he

had vomited coffee-ground vomit. There was an autopsy, which only revealed some intussusceptions of small intestine, probably caused during the death agony, and some hæmorrhage at lower end of œsophagus. This gave rise to the interesting question as to whether this could have been done by the Schultzing, even when in experienced hands. The stitches were removed on the eighth day, when the incision was found perfectly healed. Before the patient left the hospital a careful examination of the tumour was made. It had come down into the pelvis, and seemed so near that one was tempted to remove it by morcellement through the vagina. However, it was found that the uterus was adherent to the anterior abdominal wall, and this procedure was thrown aside owing to the expressed opinion of Dr. Smyly that if it were done, and hæmorrhage should occur, one could not check it by drawing down the uterus due to its adhesions. It was decided that the operation should be done from abdomen; however, the patient refused operation. Her present condition is excellent, she suffers in no way, and the line of the incision is perfectly even and firm.

Transactions of Societies.

OBSTETRICAL SOCIETY OF LONDON.
MEETING HELD WEDNESDAY, JULY 5TH, 1899.

MR. ALBAN DORAN, F.R.C.S., President, in the Chair.

THE SEXUAL DIFFERENCES OF THE FŒTAL PELVIS.

PROFESSOR ARTHUR THOMSON (Oxford) demonstrated by means of numerous diagrams and lantern slides the results of his researches into the sexual differences in the conformation of male and female pelves observable during fœtal life. We publish elsewhere an abstract of his paper on the subject published in the *Journal of Anatomy and Physiology*.

The author also showed a specimen of the internal and external genitalia of a child, æt. 3, presenting much pubic hair. The voice was bass, but she had not menstruated. Post-mortem no abnormality of the internal genitalia was discovered, but there was disease of the adrenals.

In the discussion that followed, the PRESIDENT referred to the French method of measuring the fœtal pelvis by skiagraphy, after having filled them with mercury, this method gave 21.2 mm. as the width of the pelvic brim in the male, and 17.7 mm. in the female.

Dr. GALABIN admitted that after this admirable demonstration they must give up their ideas as to the existence of any marked differences between adult and fœtal pelves. He suggested, however, that what obstetricians called the "infantile" pelvis was correctly so described. Although the author had demonstrated that the whole width of the sacrum in the fœtus was relatively greater than in the adult, yet it was true that the wings of the sacrum were more developed in the adult and must grow proportionally at a later period. He asked whether that growth took place at puberty or during childhood. If at puberty, would it not follow that since the rest of the pelvis grew more rapidly than the sacrum, there would be a certain stage of life at which there would be what they were accustomed to call the infantile pelvis, i.e., one in which the transverse diameters were not so much developed in proportion as in adult women. He said he did not see that the facts brought to their notice disproved Matthews Duncan's view as to the effect of mechanical forces in determining the form of the pelvis.

Dr. G. HERMAN said he was one of those authors who had copied the statement as to the lateral massing of the sacrum, but this was because he had been unable to obtain the information he required as to the ossification of the fœtal pelvis. He urged that Matthews Duncan's views bore on the effect of mechanical forces on the formation of the pelvis, and not on the merely sexual differences.

Mr. STANLEY BOYD commented on the explanations hitherto offered of the differences between the male and

female pelves on the strength of the supposed influence of ovarian activity, and he asked whether there was any evidence of any such action. He also asked whether the alleged differences between the larynx in the male and female were founded on fact.

Dr. HEYWOOD SMITH recalled the case of a child at St. George's Hospital in 1863, who also presented this precocious growth of pubic hair and a bass voice, in whom also there was a tumour of the adrenals.

Mr. TARGETT mentioned that he had already directed attention in a paper to the fact that disease of the adrenals in young children had an influence on the growth of the hair, coinciding in most instances with precocious menstruation.

The PRESIDENT pointed out that it was quite consistent with biology that the sexual distinctions of the pelvis should be already marked at birth, for such was the case for example with the genito-urinary tract. It would be far more remarkable if the changes only occurred at puberty.

Professor THOMSON, in reply, said he in no wise wished to discredit the views of Dr. Matthews Duncan, but it was a fact that this authority had sought thereby to explain the sexual differences. He had carefully avoided discussing the changes that take place in the adult pelvis as contrasted with the fœtal condition. He said he had not heard of this particular method of applying skiagraphy to the measurement of the fœtal pelvis, but from what had been said he was not disposed to attach much importance to the results obtained.

PERSISTENT MENTO-POSTERIOR POSITION OF THE FACE REMEDIED BY THE USE OF AXIS TRACTION FORCEPS.

Dr. LEWERS related the case of a woman in labour for many hours at her first confinement, with the os fully dilated and the membranes ruptured, where the face presented downwards and to the right. Ordinary long forceps slipped, but with axis traction forceps he at once succeeded in delivering her of a living child. This, he said, was the second case of the kind in which, after failure with the long forceps, he had been able to pull down the head by the aid of traction forceps, whereupon rotation took place, and delivery was easy. He admitted that the axis traction was superfluous, the great thing apparently being to pull down the head to a point at which the natural forces could act in the production of rotation. He hoped that those who had not done so would give the axis traction forceps a trial in dealing with this abnormality.

Surgeon-General HARVEY urged that a case in which rotation of the chin ultimately occurred could not properly be described as persistently posterior.

Mr. TARGETT said that he had often seen ordinary forceps slip under similar circumstances necessitating perforation. He mentioned that in persistent occipito-posterior position axis traction forceps gave excellent results.

Dr. W. G. SPENCER urged that the abnormality was not usually persistent, and in only three cases out of forty had he found it necessary to intervene. He showed an instrument devised by the late Dr. Luke Robinson, of San Francisco, consisting of two blades slipping one within the other which enabled one to act very efficiently on the occiput. The use of axis traction forceps under these circumstances was, he thought, unscientific, inasmuch as rotation put an end to axis traction. He thought that long straight forceps would possibly have accomplished the same end. He recommended placing a finger on the upper jaw and this method applied also to brow and incomplete face presentations. They might extend the head strongly and get an assistant to apply the forceps.

Dr. LEWERS said he had used the term persistent because labour had lasted long enough to render intervention indispensable. Failing success with the axis traction forceps craniotomy would have been necessary. Dr. Spencer, he said, was under a misapprehension as to the stage at which he recommended this intervention. It was not at a stage at which it was still possible to convert a face into a vertex presentation that interference of the kind was necessary, for at that stage they were at liberty to hope that rotation would even yet take place.

Cases in which the chin would rotate forwards after the use of the instrument shown by Dr. Spencer might well be left alone. He pointed out that in his cases the women had been nine hours in labour. In cases in which he recommended this procedure there was no longer any room for a change of position *in situ*.

NOTES ON A CASE OF ECLAMPSIA.

DR. HORACE SAVORY contributed notes of a case of eclampsia in a multipara in which complete and rapid evacuation of the contents of the bowels by copious and repeated enemata had brought about cessation of the fits. He mentioned that the amniotic fluid was an almost jelly-like mass consisting principally of meconium. He commented on the peculiarly offensive odour of the intestinal contents, and suggested that in some cases, at any rate, the eclampsia was due to a failure on the part of the kidneys to eliminate toxins caused by intestinal fermentation, or from some other source such, for instance, as the toxins resulting from the unceasing contractions of the large mass of uterine muscle.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTIONS OF OBSTETRICS.

MEETING HELD FRIDAY, MAY 26TH, 1899.

The President, Dr. F. W. KIDD, in the Chair.

SPECIMENS.

DR. SMITH showed myomatous uterus showing large abscess cavity, removed by panhysterectomy, from a woman, æt. 40, five years married, during which she had given birth to two stillborn children and an instrumentally-delivered full term child last December. The tumour was at that time a little larger than a four months pregnant uterus, and had since then grown rapidly, so that in the April of this year it filled up the entire abdomen. It was diagnosed as a fibro-myoma of a cystic nature. He attempted to do the operation of primary ligation of both the ovarian and uterine arteries, and found no difficulty in ligating the ovarian artery, but could not do so in the case of the uterine artery, owing to the weight of the tumour (2½ stone) fatiguing his assistant. He, therefore, decided to split the peritoneum in front high up, and to separate the bladder with a sponge. The bladder was so soft that in doing this he perforated it. He then discovered that the common iliac artery seemed to take the place of the uterine artery, and on separating it there was some hæmorrhage, which was checked by compression of the aorta. He amputated the uterus, and, while removing the tumour, damaged the ureter, which he clamped temporarily. The bladder was afterwards stitched with fine interrupted silk sutures, and the ureter treated in the same manner, the peritoneum being finally stitched over it. A large clot of blood which had collected in the bladder was washed out with a Bozeman's catheter, and the patient made a good recovery. The cystic contents of the tumour were found to be an abscess, which had started from the last confinement, the woman having then had septic troubles.

In reply to some remarks by the President and Dr. Purefoy,

DR. SMITH said the patient a few years ago had been in a Dublin hospital, where a diagnosis was made by making an abdominal incision, but they did not operate, the patient then becoming pregnant again. So rapidly did the tumour grow that it gave the impression of an ovarian tumour.

REMOVAL OF TUBERCULOUS OVARY.

DR. SMYLY related a case of the above which is published in full elsewhere.

PAPILLOMATOUS CYST OF OVARY.

DR. KIDD exhibited a small ovarian papillomatous cyst, with the following interesting history:—Patient, T. C., unmarried, æt. 35, was admitted to the Coombe Hospital on May 5th. She had been treated about a fortnight previously in the country for obstruction of

the bowels and peritonitis; this had yielded to treatment. After arrival she was examined, and a small ovarian tumour diagnosed. Operation on the 13th. Tumour was adherent to everything—omentum, peritoneum, and intestines—but the adhesions were comparatively recent, and could be separated with a little care. Part of cyst wall looked gangrenous, and when the adhesions were all separated it was found that there was a twist on the pedicle; it required two half turns to put the tumour in its proper place. Patient made a very rapid recovery. Temperature only on one occasion touched 99 deg. F., and stitches were removed on the eighth day. Union was perfect.

MYOMATOUS UTERUS REMOVED BY ABDOMINAL HYSTERECTOMY—DOYEN'S METHOD.

DR. SMYLY said this was the first time he had resorted to this method of operation, which, he believed, had never before been attempted in this country. The operation was performed for pain, and on opening the abdomen he found adhesions to the omentum and small intestines, in separating which there was a large number of bleeding points to control. This portion of the operation occupied three-quarters of an hour. Doyen's part, which took seven minutes, commenced with pulling the tumour out of the abdomen over the pubes. He then opened the posterior *cul-de-sac*, reached hold of the cervix with a vulsellum forceps, and decorticated it with his finger, afterwards reflecting the peritoneum from the uterus, and finishing the operation in the ordinary way. He had no hesitation in saying this was by far the best method. Besides rapidity it had other advantages, for in the older method they cut the arteries where they are largest, thereby running the risk of death from embolism or hæmorrhage. As a matter of fact he did not see a big vessel at all during the operation.

THE PRESIDENT said he had seen the cinematographic representation of the operation in Edinburgh, and he was amazed at the celerity with which an operation of such magnitude could be performed.

DR. TWEEDY asked if the operation were applicable to every form of myomatous uterus. Was it applicable where the myoma grows behind or in intra-ligamentous tumours?

DR. SMYLY, in reply, said that Doyen specially recommended this operation because he believed it to be applicable to all cases.

DR. F. W. KIDD, Master of the Coombe Lying-in Hospital, read a note on a successful case of "Caesarian Section," in which he was assisted by Drs. Heuston, Cole-Baker, and Scully. This case will be found fully reported under the head of "Clinical Records," page 34. In the discussion that followed,

DR. SMYLY remarked that every step of the operation, though apparently a simple one, was the subject of controversy. Professor Murdoch Cameron, of Glasgow, has said that the position of the child depended on the placenta, and he would like to know if this opinion was borne out in this case, and if the abdomen of the child was turned towards the placenta.

DR. PUREFOY said that, although a recent writer had advocated the low incision in preference to the fundal incision, his own experience had led him to think that the high incision was certainly the better. He thought that the careful application of the sutures and adjustment of the peritoneum had a great deal to do with the success of a case. He had always regarded Schultzing with misgivings, owing to the possibility of injury to the soft parts of the child.

DR. TWEEDY did not see the necessity of avoiding insertion of the ligatures right through the endometrium if the uterus were aseptic, and this method gave a firmer union in his opinion. Lusk says that an incision is made low down in the uterus in order to avoid hæmorrhage, whereas it has been recently claimed that an incision through the fundus, the most muscular portion of the uterus, obviates much hæmorrhage.

DR. KIDD, in reply, said the child was very nearly in the left occipito-anterior position, and the placenta was more over to the right of the mother. He was not opposed to Schultzing, and he thought that Sylvester's method was far more likely to cause hæmorrhages. With

regard to the question of suturing, he had no guarantee that the uterus was aseptic in this case.

The Section then adjourned.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY. MEETING HELD JULY 5TH, 1899.

Sir JOHN BATTY TUKE, President, in the Chair.

MR. STILES showed—1. A child two months after operation for large hydronephalocoele, involving by far the larger part of the cranium, with stereoscopic photographs before and after operation. 2. Child after operation for extensive tuberculous osteomyelitis of the tibia, with skiagrams. 3. Child after excision of the wrist for tuberculous disease, with skiagrams.

DR. ALEXANDER BRUCE showed a patient with typical auditory aphasia.

MR. STILES and DR. RAINY showed skiagrams of tuberculous ankle, of separation of the lower epiphysis of the humerus, and of fracture at the junction of the upper and middle thirds of the shaft of the femur, showing typical displacement of the upper fragment.

DR. ALEXANDER BRUCE showed microscopical specimens of amyotrophic sclerosis of progressive muscular atrophy. The latter showed a degeneration absolutely limited to the anterior cornua, and not affecting the pyramidal tracts.

DR. HARVEY LITTLEJOHN showed—1. Specimen of strangulation of the intestines by the omentum. 2. Intussusception of the ileum. 3. Stomach and bowels from a case of poisoning by hydrochloric acid; and 4. Similar viscera from a case of poisoning by zinc chloride and hydrochloric acid.

MR. COTTERILL showed a dermoid cyst of the ovary.

DR. BRUCE and MR. COTTERILL read a paper on a case of

CEREBELLAR TUMOUR, CONSIDERED FROM THE POINT OF VIEW OF LOCALISATION AND OF TREATMENT.

The patient was a man, *æt.* 34, a total abstainer, and free from any sign of syphilis. Five years ago he was seized with deafness in the left ear, which soon became absolute, and has remained so ever since. About three years ago he began to have difficulty in walking, and constantly felt as if he were about to fall over to the left side. He could always feel the ground distinctly under his feet. He then noted that in order to carry out any voluntary movement with either the left arm or leg he had to pay great attention to every part of the action, and could not do it with the same ease as in the case of the right limbs. His gait then became staggering, and seven months ago he had several attacks of vertigo, followed by left-sided occipital headache, which has been continuous ever since. For about the same period he has had some dimness of vision, especially in the left eye. On examination, the patient had a somewhat depressed look; his temperature was subnormal, but, with the exception of the nervous symptoms to be described, all the bodily functions were healthy. He complained of pain in the back, and of left occipital and parietal headache, with tenderness on percussion over the side of the cranium. Common sensibility was normal, except for a degree of anæsthesia of the left conjunctiva. The muscular sense, as tested by weights, was normal, but when the eyes were closed he could not touch a given part of the body with his left arm or leg. Smell was normal. There was total deafness in the left ear due to nerve lesion. Taste was impaired over the anterior two-thirds, and probably also over the posterior third of the left side of the tongue. There was double optic neuritis, most marked on the left side. Slight nystagmus was present in all positions of the eyes; it became much more rapid when the patient looked to the right. When he looked to the left the excursion of the eyes became slower and more extensive. Convergence was good, the right visual field was normal, and the left slightly contracted. The left pupil was somewhat dilated. There was some paresis of the left facial nerve, and difficulty in moving the tongue to the right side. The grasp of

the hands was equal, there was tremor of both arms, but much more distinctly on the left side; there, indeed, it closely resembled an intention tremor, but was slower and less rhythmical. The movements of the left leg in walking were stamping, and at every sixth or seventh pace the patient tended to fall to the left side. This was most marked when he walked along a straight line; there was, however, no Romberg's system. The knee jerks were equal. In discussing the diagnosis, Dr. Bruce referred to the paper which he had previously read to the Society, in which the connections of the cord and cerebellum had been traced. This case was a clinical proof of the correctness of the facts he had then brought forward. All the fibres of the cord going to the cerebellum end in the middle lobe, thence they communicate with the roof nucleus, from which fibres run to the nucleus of Deiters of the opposite side. Deiters' nucleus is the nucleus for the vestibular root of the auditory nerve, and sends fibres to the nucleus of the sixth nerve of the same side, and to both third nerve nuclei. It also gives off descending fibres to the anterior cornua of the cord. The function of Deiters' nucleus appears to be to give tone to the muscles, and to relieve the higher centres of the necessity of controlling every detail of a voluntary movement. All the symptoms of this case—the difficulty in performing voluntary movements, the uncontrolled and irregular movements of the eye muscles, and the staggering gait, pointed to a lesion pressing on Deiters' nucleus and the restiform body, and interfering with the arc described above. The question then arose as to whether the tumour was a surface one, or whether it had begun in the substance of the cerebellum. On account of the early onset of the deafness it seemed most likely to lie on the surface. The two most common tumours in this region were tumours of the flocculus and of the petrous temporal. The latter were usually simple fibrous tissue growths, and were pedunculated, so that in view of this possibility, and as the patient was steadily getting worse, Dr. Bruce had asked Mr. Cotterill to operate.

MR. COTTERILL said that he had never been very sanguine about the case, although he agreed with Dr. Bruce as to the probable site of the tumour. In order to get free access to the cerebellum he had removed the whole of the lower part of the occipital bone, and was able to push the cerebellum to the right, so as to explore the left side with the finger. Unfortunately the patient lost a great deal of blood during the removal of the bone, and death (which occurred two days after the operation) was probably hastened by this. The tumour was found to be in the flocculus, and was beyond the reach of interference.

DR. FOULIS read a paper entitled

SOME OBSERVATIONS ON THE DEVELOPMENT OF THE TESTICLE.

The paper, which was illustrated by microscopic slides and diagrams of the developing testis of the embryo deer, went to show that the tubuli seminiferi were homologous with the egg ducts of Pflüger in the female ovary.

France.

[FROM OUR OWN CORRESPONDENT.]

PARIS, July 8th, 1899.

AORTITIS FROM MALARIA.

AT the meeting of the Academy of Medicine, M. Lancereaux spoke on a special form of aortitis to be met with in persons who had suffered more or less from intermittent fever. The affection was to be observed more particularly in men between the ages of thirty and sixty, and was seated exclusively in the ascending portion of the cross of the aorta, and commenced by infiltration and thickening of the external tunic. The middle tunic thus compressed became atrophied, and finally disappeared; the inner tunic became hyper-

trophied and coated with wrinkled patches. The consequences of those lesions were an inflammation of the peri-arterial tissues, notably the cardiac plexus and the appearance of angina pectoris. On the other hand, the destruction of the middle coat of the vessel contributed frequently to the formation of a saciform aneurysm. Of thirty-seven patients observed by the speaker, all suffered from angina pectoris, and eight presented the signs of aneurysm. The evolution of the affection was very slow. The prognostic was not favourable, the affection frequently terminating with sudden death. The treatment was iodide of potassium and milk diet, with sedatives for the angina. Injections of a solution of serum and gelatine might be tried when the aneurysm was well formed.

HEMATOCELE.

M. Regnier insisted on the danger of treating hæmatocele through the vagina, instead of which laparotomy should be in all cases preferred. A short time ago he incised the tumour through the posterior *cul-de-sac*, and the hæmorrhage was so alarming that he had to perform laparotomy to remove the cyst. In a second case he was obliged to leave several forceps *a demeure* to control the hæmorrhage. Both patients recovered.

M. Poyz said that although he was a great partisan of laparotomy, he frequently opened hæmatocele by the vagina, and was always able to control the hæmorrhage by plugging.

TUBERCULOSIS AND ALCOHOLISM.

M. Barbier declared that from statistics he had collected on pulmonary phthisis at his hospital, he found that 70 per cent. of cases were those of persons who came to Paris from the provinces, and in all of them the malady terminated rapidly by death. The speaker said that in 98 per cent. of these cases intemperance was admitted.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, July 8th, 1899.

At the Society for Scientific Medicine of Königsberg, privat docent, Dr Rosinski related a case of

HEREDITARY SYPHILIS

that was the first in which ovular transference of the disease could be proved with certainty. A lady of good family, married six years, with one healthy child, contracted a bad attack of syphilis, the source of which was subsequently found to be a servant maid; the husband remained healthy throughout. Several courses of inunction were carried out, and three months after the last the patient became pregnant again. She aborted in the sixth week, and the fetus, 16 mm. long, already showed signs of syphilis of the liver. On examining the placenta, the maternal portion was found to be a good deal diseased, whilst the chorionic villi were perfectly healthy. The speaker concluded that the ovary was the source of the syphilitic infection of the fetus.

At the Congress for Medicine, Dr. Von Schrötter, Vienna, related a case of

GAS ABSCESS

in the abdominal wall of a man, æt. 67. By puncture, 25 ccm. of gas were removed, and by incision discoloured, offensive pus was evacuated. Bacteriological examination showed bacterium coli. A fistulous tract led deeply

downwards. The affection was probably periphlebitic (perityphlitic?). It was of importance not only pathologically, but also clinically, that gas phlegmons, gas abscesses, and abscesses with gas should be more strongly distinguished.

Hr. von Noorden, Franfort, a/m, read a paper on

THE TREATMENT OF CHRONIC KIDNEY DISEASE.

He said that in chronic contracted kidney not nearly so much importance was placed on absolute limitation of albumen as in the other forms of nephritis. When one reckoned up what was permitted of milk, eggs, meat and vegetables, the quantity of albumen was found to be above rather than under 100 grms. Others laid stress on the selection of the meat, and allowed contracted kidney cases only the white flesh of fish, birds, veal, &c., whilst the brown flesh of slaughtered animals, game and fowls was strictly forbidden. Many patients gradually acquired such an objection to white meat, that its consumption was reduced to a minimum, appetite fell away, and disturbances of nutrition came on. The chief difference between brown and white meat lay in the colouring matter, and this we had no ground for holding injurious. From his own observations he was opposed to the view of the harmfulness of brown flesh. Patients fed on white flesh excreted rather more urea than those fed on brown flesh containing equal quantities of nitrogenous material.

As regarded liquids, either, nothing was said or large quantities were recommended for flushing out the kidneys. Ziemssen in his handbook had recommended limitation of the liquids even when arterio-sclerosis of the kidneys was present. By observations during six years, the speaker was convinced that cases of contracted kidney were extraordinarily benefited by limitation of liquids to 5/4 or 3/2 litres per diem. Patients in whom the heart had begun to fail did not often last over a month. In these cases limitation of the liquids was of the highest value. In nearly thirty cases the results were good, the cardiac asthmatic attacks ceased, sleep returned, ordinary diuresis returned, and the cardiac dilatation undoubtedly improved. This favourable condition in many patients kept up for several months and even years. Even in desperate cases where no treatment could be any longer of use, limitation of liquids was advantageous. The best that could be done was to keep the patient in the *statu quo*.

Hr. Ewald, Berlin, had long been in favour of limiting the quantity of liquids in chronic renal cases. His view being based on the idea that a damaged organ should not be overburdened with work. He determined the quantity of urine passed by Oertel's method, and regulated the quantity of liquids by that, if possible remaining below the quantity excreted. He had always acted on this principle both in contracted kidney and in parenchymatous nephritis. By regularly estimating the quantity of albumen, he had convinced himself of the fact that the kind of albumen used, whether of egg, brown or white flesh, was of no consequence, as far as the excretion of albumen was concerned.

Hr. Petersen, Heidelberg, read a paper on

SURGICAL PROCEDURE IN BENIGN DISEASES OF THE STOMACH.

About 300 cases of surgical procedures in non-malignant diseases of the stomach had been recorded. Seventy-seven such operations had been performed at the Heidelberg Klinik. The principal indications were (1) absolute

stenosis of the pylorus, 57 cases. The stenosis was caused forty times by ulcer, eight times by cholelithiasis, four times by cauterisation, once by tuberculosis, &c., two after failure of internal treatment, gastralgia, uncontrollable vomiting, the so-called rebellious forms of ulcer (five cases), and six times from dangerous hæmorrhage. Eight of the seventy-seven cases died, or 11 per cent. Advances in surgery shone out, when the cases were divided into two periods:—before 1895 thirty-three operations, with seven deaths = 22 per cent.; since 1895, forty-four cases, with one death = 2·3 per cent. This striking advance was brought about by having the patients in a better state for operation and by increasing experience in the selection of cases, and, secondly, by improved technique, and, above all, by the introduction of Murphy's button. This reduced the length of an operation from three-quarters of an hour to one-quarter; permitted nourishment from the first, and avoided the so much-dreaded spur formation between the upper and lower ends of the bowel. Trustworthy after reports were available concerning forty patients who had been operated on over two years. In the cases of stenosis the reports were at first satisfactory in the better selected method of operation. In gastroenterostomy the permanent recoveries were 99 per cent. In the case of gastralgia 10 per cent. were improved, 90 were completely cured, either by gastroenterostomy or simply by the separation of adhesions. In six cases of hæmorrhage recovery was complete, twice by excision and in the other case by gastroenterostomy. In one case of ulcer, the bleeding was arrested by gastroenterostomy, although the ulcer itself was not treated. If such cases were repeated it would place the treatment of ulcer of the stomach on a new basis.

The changes in the stomach after gastroenterostomy were important. Dilatation receded quickly, but rarely disappeared. The motor function was normal in nearly all cases. Lactic acid disappeared. After operation bile was frequently found in the stomach. Neither the absence of gastric juice nor the presence of bile caused any visible disturbance. A functioning sphincter gradually developed at the fistulous opening. The total results of the period named were before 1895:—Mortality, 25 per cent., uncured, 15 per cent., improved, 10 per cent., permanently cured, 50 per cent.. Since 1895, mortality, 3 per cent., uncured, 6 per cent., improved 10 per cent., permanently cured, 80 per cent.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, July 8th, 1899.

THE TREATMENT OF EPILEPSY.

BECHTEREW in his reports on epilepsy, speaks favourably of combining some cardiacs with bromide of potassium. The simple administration of bromide without this precaution will not succeed. He has now patients under observation treated three years ago in this way who are still free from the attacks, which can only be accounted for by this cardiac combination, as all other conditions are similar to former treatment with bromide alone, with only temporary success. For some time past he has used an infusion of adonis vernal, 2 (30·8 grains), to 2·8 grammes (42 grains) of the solid in

180 c.c. of water (6·53); to this is added 13 grammes (3·1 drs.), of which 6 tablespoonfuls may be taken in a day. Where there is a depressed state of mind with general irritability, codein is combined with this mixture. Other vegetable cardiacs are equally good, such as digitalis, of which 0·5 to 9·75 grammes (7·7 to 11·57 grains) of digitalis may be given as an infusion in 180 c.c. of water (6·53). To this may be added sodium and potassium bromides of each to 8 grammes, with 0·15 to 0·2 gramme (2·3 to 3·0 grains.) Of this mixture four to eight tablespoonfuls may be given daily without any cumulative effect. Von Bechterew is persuaded that these cardiacs are as beneficial in the treatment of epilepsy as the sedatives, as they favourably influence the heart and vascular apparatus, as well as hasten the elimination of unnecessary nitrogenous products, such as toxines, from the hæmic circulation.

The same combination of cardiacs and sedatives will be equally beneficial in neurasthenic cases.

FRIEDREICH'S ATAXIA.

Cohn relates two cases of this disease under his care from the same family, in which the parents were addicted to drink, one of them being tuberculous. The two brothers when children developed progressive tendencies towards ataxia. Cohn gives the following symptoms present: static and locomotor ataxia, absence of patellar and Achilles reflex, cutaneous sensibility intact, though the feeling of location was disturbed, bladder and bowel normal, nystagmus, slight disturbance in speech, with Friedrich's symptomatic foot, and one of them had atrophy of the optic nerve. He differentiated the diagnosis from chorea infantilis, multiple sclerosis, tabes, hereditary syphilis, ataxic paraplegia, cerebral tumour, or héréd-ataxie cérébelleuse. Cohn adds the optic atrophy to the symptoms of Friedrich's ataxia. The head symptoms were tic-like, while the fingers reminded one of athetosis or chorea by their irregular movement, but partially present during repose as in the ataxia of tabes.

The disposition to the disease is assigned to the drunken habits of the father and an attack of scarlet fever which they had when young; but drinkers are notably common origins of the disease. The therapeutics he recommends are nourishing diet, massage, and compensating exercise similar to that of Fraenkel.

PARTIAL IMMUNITY OF THE SPINAL CORD.

Adamkiewicz has again instituted another hypothesis for the immunisation of particular parts of the spinal cord in syphilitic tabes. It is well known that when all the muscles are fatally injured by this disease the muscles of mastication, deglutition, respiration, and cardiac motion are unaffected; this is common to all other ascending paralysees. This relative immunity to morbid changes was undoubtedly due to the providential arrangement of the blood supply. Injections of coloured agents into the arteria magna spinalis or from the arteria basilaria, will not penetrate further than the lower margin of the medulla oblongata. Again the transmission of blood by the arterio-vertebro-spinalis meets with great resistance when injecting into the cord. Another point of note in this direction is the narrow calibre of all the vessels in the medulla oblongata which will act as a protection on the larger ganglion. Perhaps the most potent cause was in the nerve system itself, which in the medulla was less active than in other parts of the neurotic system, and this

combined with the hæmic protection, was enough to explain the constant exemption of this part of the cord.

TOXIC LOCAL CENTRES.

Bruno has announced another theory of cerebral localisation which may be carried to an indefinite length. It is well known that guinea pigs are very refractory to morphia, while the intra-cerebral injection of 0.001 to 0.006 gramme (0.03 grain to 0.09 grain) into the anterior right angle of the cerebrum between the coronal and saggittal sutures, three millimetres deep, will produce rapid clonic and tonic contractions terminating in death.

Sodium chloride, urea, sugar, and Glauber's salts, when similarly injected, have no action whatever. Ferrocyanide of soda is another harmless drug to the guinea pig, but when injected in the same manner is fatal in very small quantities. Subdural injections require very large doses which produce severe tetanic symptoms from which the animal speedily recovers. Methylen-blue is another drug resisted by the same animal, but injected into the brain is fatal.

At the post-mortem the colouring stuff was to be found in the cortical part of the brain, the fluid of the ventricles as well as in the delicate lining.

PROGRESSIVE PARALYSIS.

Greidenberg tells us that the incidence of the disease is now transposed in asylums of the insane for what reason he is unable to determine. The disease was up to recent date greatest among men, but at the present time the larger number are females.

Continental Notes.

(FROM OUR SPECIAL CORRESPONDENT.)

AIX-LES-BAINS.

AIX-LES-BAINS has had a successful spring season. Every year it is attracting more and more British visitors; many returning from a winter residence in Italy and on the Riviera, who are not invalids, find Aix and the picturesque hills and valleys of Savoy and Dauphiny very agreeable resting-places for April, May, and June. Prior to the Franco-German War, the total number of foreigners of all nationalities annually visiting Aix-les-Bains rarely amounted to 10,000. This number has increased steadily. In 1869, 10,000 British and other foreign visitors; in 1879, 17,000; 1889, 24,000; 1897, 32,000. This year the British visitors have remained longer than usual; some until the end of June, possibly owing somewhat to the weather and somewhat also to the additional attractions of Aix. During the past winter various important improvements have been made to the Bath establishment, and to the two Casinos. The "*Grand Casino and Cercle*," always a very attractive resort, has been much enlarged and improved. The grounds are a picture of landscape gardening; the new Concert-Salon and the new Theatre are elegantly and artistically designed. Under the able and experienced supervision of Mr Gandrey, all the arrangements are excellent, and the musical and dramatic performances most satisfactory; so that the Concerts, Comedies, and Operas have always a full and fashionable attendance.

The hot *douches* and *massages* at the Baths of Aix dispose invalids for much active exercise, so that the very agreeable "*distractions*" of the Casinos are valuable adjuncts to "the cure" here, as are also the comforts and

luxuries of excellent hotels, which are numerous at Aix-les-Bains. Two other valuable adjuncts to Aix have not yet received the attention they really merit—namely, the waters of Saint-Simon and Marlioz. The Rapy Spring at Saint-Simon (about twenty minutes' walk northerly from Aix) yields an abundant supply of an alkaline-magnesian water, similar to that of Evian, efficacious in chronic gastric troubles, and claimed to lessen "the formation of uric acid in gouty and rheumatic complications" (Dr. Bonjean). The Saint-Simon water is pleasant to drink, either with or without admixture with wines. It is a superior table-water, and so light that 15 to 20 glasses may be taken agreeably daily.

At Marlioz (about thirty minutes' walk southward from Aix), there is a small establishment for the application of the waters there in baths, douches, injections, and inhalations. The spring yields a cold sulphurous water containing sulphuric soda, iodine, bromine, and sulphuric-acid gas. Dr. Macé strongly recommends it for chronic mucous affections, asthma, &c.

Yet another very valuable adjunct to the Baths of Aix is their beautiful situation, amidst hills and vales on the lake shore, inviting excursions, near and far, on every side. Montaigne said:—"He who does not bring with him so much of cheerfulness as to enable him to enjoy the amusements and the pleasure of the company he may meet there, and the walks and exercises, to which the beauty of the neighbourhood invite us, must assuredly lose the best part of his visit to any Baths. For this cause I choose those places most pleasantly situated, and where are the best lodgings, provisions, and society."

All these "indications" of the old philosopher abound at Aix-les-Bains!

The Operating Theatres.

ST. MARY'S HOSPITAL.

CIRROID ANEURYSM OF THE SCALP.—Mr. QUAREY SILCOCK operated on a girl, æt. 18, who had been admitted by reason of the presence of a cirroid aneurysm of the right side of the scalp, involving the supra-orbital and superficial temporal arteries, and occupying an area three inches in diameter immediately over the eyebrow, and extending backwards into the hairy scalp. The history was, briefly, that the girl had a fall on her forehead when 3 years old, and since then the aneurysm had formed, and had been gradually increasing in size. Efforts had been made in other hospitals to deal with it by ligature of the afferent arteries, but with total want of success. It was therefore decided to excise the tumour. This was done in the following manner:—The scalp was shaved, together with the eyebrow, the skin rendered aseptic, and a circular incision through the skin at the periphery of the area beginning at the inner side was made down to the pericranium aneurysmal area. Pressure was kept up on the different arteries as far as possible in order to control the hæmorrhage in some degree. The bleeding, however, was very considerable, in spite of the fact that small portions only of tissue were cut at a time, pressure forceps being applied to each bleeding point as it arose. Finally the whole mass was circumscribed and the entire aneurysmal area of scalp removed, leaving a gap about the size of the palm of the hand. At one corner

of the wound two sutures were inserted after freeing the edges of the wound a little, but the remainder of the raw surface was left to granulate. Mr. Silcock said that the previous methods of treatment, which may have included others besides that of ligature of afferent arteries, had proved entirely unsatisfactory, therefore it was only left to him to perform excision. This he had accomplished with the aid of about three dozen pairs of pressure forceps, so diffuse had been the hæmorrhage. He remarked that these growths were not really of the nature of a neoplasm, but were a change affecting particular vascular territories, giving rise to dilatation and tortuosity of the arteries, originating possibly in some congenital fault, as in this case in an acquired condition, generally initiated by an injury. He pointed out that the patient was an absolutely healthy country girl. He said that a portion of the pericranium in the centre of the area had to be removed since the tissues of the affected scalp could not be separated therefrom.

Subsequently, in about a month's time, when the whole area was granulating, it was grafted after the method of Thiersch, the superficial granulations being first scraped away. The wound by this time had considerably contracted, but there remained an undue amount of deep seated pulsation just above the eyebrow; the latter had not been encroached upon at the time of the operation, by reason of the subsequent deformity which would have resulted. This pulsation, however, was gradually becoming less marked, and Mr. Silcock did not think the condition called for further interference.

KING'S COLLEGE HOSPITAL.

AMPUTATION OF BREAST FOR SCIRRHUS, FOLLOWED BY SUPRA-CLAVICULAR EXCISION OF GLANDS.—Mr. CARLESS operated on a single woman, æt 50, who had noticed a lump in her left breast for about six weeks. This was attributed to cold. There had been no injury, and the patient had complained of no pain. Two or three cases of carcinoma had occurred in the family. A well-marked tumour could be felt in the outer and upper quadrant of the left breast, which was larger than its fellow, whilst the nipple was a little raised. The skin over the tumour did not dimple on movement, but felt thicker than elsewhere, and the sebaceous glands were more obvious. This condition of the skin was present for an area at least three inches in diameter, although there was no discolouration. The axillary glands were considerably enlarged and reached well up into the apex of the axilla, several glands also could be felt enlarged above the clavicle. The breast was removed together with the sternal portion of the Pectoralis major, the Pectoralis minor, and the axillary glands and connective tissue through two crescentic incisions, enclosing an ellipse of skin with its long axis transverse, and including the affected area of skin already mentioned; another incision was made at right angles to the upper of the two along the border of the Pectoralis minor. In this way the area of operation was well exposed, and it was not difficult to remove the whole mass in one portion. The wound was closed with some little difficulty, so as to produce a T-shaped cicatrix; one or two deep silver stitches with lead buttons had to be employed. Mr. Carless pointed out that although at first sight this case seemed a favourable one, in reality it was anything but of that nature. The extensive glandular infection and the

very definite though invisible invasion of the skin, together with the family history of malignant disease were a sufficient warrant for the extensive operation he had just undertaken, and which he proposed to supplement in a few days by clearing out the supra-clavicular fossa. Had the patient been strong and robust, he would have undertaken the two proceedings at the same time, so as to make certain that nothing should be left between the supra and infra-clavicular fossæ; but, seeing that she was a somewhat feeble old woman, he thought it better to do the operation in two stages. There was no question in his mind as to the value of removing the pectoral muscles in addition to the breast and axillary contents, but he would limit the removal to cases where the tumour is obviously fixed to the Pectoral, or where there is much axillary trouble. His experience did not show that the movements of the arm were seriously crippled, especially if the patient could be nursed with the arm at right angles to the trunk, but in this particular instance so much skin had been taken away that it would be necessary to keep the arm to the side. The deep stitches would be removed in 24 hours and the drainage tube in 48 hours.

The wound healed by first intention throughout, and ten days later the supra-clavicular operation was proceeded with. An incision was made down the posterior border of the Sterno-mastoid and outwards along the clavicle, the flap of skin thus marked out was dissected up, and the whole of the glandular contents and connective tissue lining the posterior triangle were cleared away from before backwards, the jugular vein at its junction with the subclavian being first exposed, and great care being taken not to damage the thoracic duct. Considerable development of cancerous glands was in this way removed. Mr. Carless alluded to the fact that Professor Halsted, of Baltimore, was clearing the supra-clavicular fossa as a routine measure in all cases of scirrhus mamma, and that surgeon has found that in a large percentage cancer is present, although no enlargement could be previously detected by palpation.

It is satisfactory to note that the second wound healed throughout by first intention, and that the patient was enabled to leave the hospital three weeks after the first operation.

The Medical Sickness and Accident Society.

The usual monthly meeting of the Executive Committee of the Medical Sickness, Annuity, and Life Assurance Society, was held on the 30th ult. at 429, Strand, W.C. There were present—Dr. de Havilland Hall in the chair, Dr. J. B. Ball, Dr. J. W. Hunt, Dr. F. R. Mutch, Mr. J. Brindley James, Dr. Francis J. Allan, Mr. F. Swinford Edwards, Dr. M. Greenwood, Dr. Walter Smith, Mr. William Thomas, and Dr. W. Knowsley Sibley. At the last general meeting of the Society held in May it was resolved that a cash bonus of 10 per cent. on all sickness benefit premiums paid during the last five years should be allotted to the members. The claim list during the first half of 1899 has been somewhat heavy, but, nevertheless, during the six months the income of the Society has been so much greater than its outgo that the whole amount necessary to pay this bonus has been saved and no sale of securities will have to be made. The necessary clerical work is nearly complete, and arrangements are being made by which the members may receive the bonus cheques at the end of this month. Prospectus and details may be obtained on application to Mr. F. Addiscott, 33 Chancery Lane, W.C.

WEDNESDAY, JULY 12, 1899.

THE LONDON UNIVERSITY QUESTION.

At last there seems some prospect of London having what it has long, very long wanted, and that is an University like those in most Continental cities, and now in this country in some great centres. When the University of London was started more than half a century ago, it was by the help of those who wanted religion excluded from the studies and graduation of students, and that admission should be provided to the learned professions for those who were prevented, for certain reasons, from obtaining distinction and degrees at Oxford or Cambridge. To found an University, however, is a matter of difficulty. The capital required is great, and the poor London University was not so provided that it could develop as it should be able to do. Change after change took place, and at last the University of London became nothing but an Examination Hall where no education or training was supplied, and all that was done was to test the relative merits of candidates for degrees. Examinations may be very good things in their way, but it would not be difficult to prove that the best men in after life are not always those who have led at the beginning of the race. The London University has become more and more limited in its use in assisting in the education of our younger men, and it has become more and more apparent that what is wanted in London is some such University as every great city on the Continent provides for the sons of those residing in it, and where proper education of every kind is associated with and leads up to a Degree. Science must be taught by competent teachers, and cannot be learnt from books in the way that is possible with

classics and mathematics. What is wanted now is technical education, and this can only be acquired by the personal contact of student and master. The opening up of the world can only be effected by Practical Science, by such powers as are wielded by the engineer, and by young men trained to go out into the world and work where civilisation has not yet developed uncultured resources. In choosing Kensington, where Science-Education has been at work now for some years, a wise course has been taken, and we think that our profession ought to aid in every way in supporting this New University, for we want in London some such place for those who intend to devote themselves to the Practice of Medicine. Between the time when a boy leaves school and joins a hospital a year or two may well and should be spent in the study of those sciences with which medicine is more or less closely connected, and a knowledge of which is certain to prove of great value in many ways to the medical man. This is more felt now than it was a few years ago, as Sanitary Science has become an important matter both to the public and to the profession, and it is not easy for our hospitals to provide the means of educating in much that is really outside the hospital, and is not a part of hospital work. The education of our working classes, and the great system of School Boards may interest many, and is truly an important work, but the youths of the middle class ought not to be neglected, and good teaching is not to be obtained without assistance. Let those, therefore, who are interested in the training which is proper for the medical profession, and who realise the great importance of having high-class men to carry out its work, be generous in assisting the objects for which this new university is intended.

THE ANNUAL ELECTION AT THE ROYAL COLLEGE OF SURGEONS, ENGLAND.

THE annual election to the Council of the Royal College of Surgeons, England, took place last week, and resulted in the return of Mr. Herbert W. Page at the head of the poll with 286 votes, while Mr. T. R. Jessop was re-elected with 233 votes. Thus Dr. Ward Cousins, the president-elect of the British Medical Association, failed to secure his re-election. Dr. Cousins's career upon the Council has been somewhat a chequered one. Within a period of four years he has had to seek the suffrages of the Fellows upon three different occasions. He was first elected to the vacancy on the Council caused by the death of Mr. Hulke; after having filled the period of Mr. Hulke's term, he had again to appear at the poll; upon that occasion the votes which he obtained only placed him in the position of filling another death vacancy—namely that of Mr. Rivington's. This term expired in the present year, so that Dr. Ward Cousins had last week, for the third time in four years, the necessity of seeking the support of the Fellows for a seat on the Council. Such a record is quite unique in the annals of the Council elections. Dr. Ward Cousins was originally

a candidate whose claims were supported by that reforming body—the Association of Fellows, and as long as the Association continued its active interference his election was practically assured. During the past two years, however, the reforming section of Fellows has taken no active part in College politics, having for various reasons, preferred to remain in this connection in a condition of suspended animation. The effect of this decision has become apparent in several ways. First and foremost there has been a very perceptible decline in the general interest displayed in the annual election. The personal interest alone is not sufficient to infuse excitement into the contest; unless the candidates appear before the constituency pledged to support rival interests it is only natural that the Fellows should abstain from troubling themselves to make use of their electoral privilege. Nothing could better display the languid manner in which the Fellows took part in the last election than the meagreness of the official figures relating to the poll. Out of a total of about 1,200 Fellows only 493 recorded their vote, namely, 477 by post, and only 16 personally. That is to say, no fewer than 40 per cent. of the Fellows failed to consider it necessary to fill in their voting paper. This, then, being the present state of affairs, the elections at the College may now be regarded, in political language, as of the nature of bye-elections, at which candidates are returned on side issues, that is to say, independently of the larger and more important questions of reform, so far as the government of the College is concerned. Just as in the political world, bye elections are regarded as of little value as a test of the drift of public opinion, so in the College elections, as at present conducted, no importance need be attached to the *personnel* of those who are successful. In the absence of candidates representing a rival platform, it really does not matter who is returned at the annual election; there is no burning question of reform at present agitating the constituency, and the organisation of the Association of Fellows for the time being having ceased to be active, there is practically nothing left to stimulate the Fellows into signing their voting papers beyond the personal interest which they may happen to take in a friend who goes to the poll. But this dull and decidedly tame condition of affairs will not always continue. The generation which initiated the reforms carried out by the Association of Fellows has done its work, and the good work which it accomplished from the year 1884 onwards is not likely to be overlooked by future historians of the College. Moreover, several of the present members of the Council were returned under its direct influence, and thus the old-timed Conservatism of the Council has now for some years been leavened by the more opened-minded liberalism of the advocates of reform. Still, the time is bound to come again when the conservatism of the Council will be found to be out of joint with the age, and whenever that time does come it is certain to happen that the annual elections will begin again to excite interest and attention.

THE IRISH "SCALE" FEE SYSTEM.

It is not very remarkable that Mr. Gerald Balfour, being a Scotchman and naturalised Englishman, took with him to Ireland, as Chief Secretary, the ingrained belief in the English small fee system. He knew that, in England and Scotland, the distribution of medical services for a few pence had, through the agency of Medical Clubs and Aid Associations, come to be universal, and he thought, truly, that a similar low fee system, if not already available, would be very useful to so poor a country as Ireland, and he went determined to provide such a system. Someone, who must have been an Englishman because no one who knows Ireland would have suffered from such a hallucination, told him, before he started for Dublin, a very palpable untruth, to the effect that now Poor-law Medical Officers were bound by etiquette not to accept less than a guinea visit, and were wont to charge that sum to every roadside cottager who required their services, and that, therefore, it had become necessary to provide with gratuitous medical services every individual who said he could not pay the statutory guinea. One would have supposed that a week in Ireland and a quarter of an hour's conversation with the medical inspectors under the Local Government Board would have dissipated this illusion, especially as most of these inspectors had themselves followed the plough as dispensary doctors, and had been glad to accept 5s. or less for a visit, and knew well that others cheerfully accepted half that sum. Whether they were afraid to tell him anything discordant with his own view or not they did not alter that view, and, notwithstanding numerous written and verbal assurances from deputations, he remained "of his own opinion still" that every Irish doctor stands out for his solid guinea in every case, and he set to work to force the doctor into conformity with the English-Scotch system. His first course was to refuse absolutely to do anything to mitigate the monstrous abuse of the Irish system by which any individual—however opulent—is entitled to receive medical relief as a pauper at the expense of the ratepayers. This abuse he preserves and cherishes as a means of forcing the Irish doctors into the English penny-a-week club system. Be it understood that we are favourable to this system under certain conditions, but the attempt of the Chief Secretary to force Ireland to adopt it demonstrates how little he knows of the Irish lower classes, and how badly advised by the Local Government Board he is. The Irish cottage peasantry and small artisans are, at present, totally incapable of mutual organisation for any beneficial object or for any object which will take a penny a month out of their pocket. They will attend a "demonstration" on some political subject in the chapel yard, and will contribute a few pence when they must, but no one ever heard of one of them insuring his life or his house. Still less will they pay for anything which they can get just as good for nothing, and, as successive Local Government Boards have trained them up in the conviction

that they all, even the farmer with £500 in bank, are entitled to free medical advice and medicine from the dispensary doctor, they are not such fools as to pay their money into a club. Therefore, until they find that that privilege has been taken from them they will "club" not one penny.

Notwithstanding these considerations, the Chief Secretary made a scheme which became law with the new Local Government Bill. The doctors of every union were to put their heads together as to what their fees to poor persons ought to be, and to submit a scale of such fees to their guardians, who *might* adopt it and, this done, it was supposed to become binding on doctor and patient. If the scale so approved suggested 2s. 6d. for a visit a mile from home, the doctor, on receiving the necessary ticket, was bound to accept that sum, and no more, no matter who presented it. But Mr. Balfour's scale system went to pieces at once; in fact, it is extraordinary that it hung together at all. First, the doctors were not obliged to submit a scale unless it was demanded by the guardians, and most of them shirked doing this. Secondly, most of the guardians, for obvious reasons, did not wish for any fixed scale, and they carefully forgot to ask the doctors for it. In these unions nothing at all was done. Thirdly, in a minority of unions the guardians, under pressure of Local Government circulars, called upon the doctors for a scale, and the doctors, under similar pressure supplied it, but when submitted to the guardians, it was in most instances scouted by them who asserted that 2s. 6d. was an altogether exorbitant fee. In some cases the document was sent back two or three times for amendment before adoption, and in many the "scale" was repudiated altogether. The beauty of the statesmanlike arrangement was that the guardian who was inclined to abuse his privilege was left in full enjoyment of that privilege. He could give his opulent next-door neighbour an absolutely free ticket as a "poor person," or in the rare case in which he or his friend was endowed with a conscience he could give him a half-crown ticket, which no doubt would be a consolation for the doctor, who would receive that sum, instead of a guinea, without the satisfaction of grumbling. This precious "scale" system has pleased no one but the trafficking guardian, to whom it has given another chance of perpetrating a fraud on the doctor. It has done not one atom of good to the sick poor. It has not attracted one individual, and it has repelled many. Let us, for the sake of Mr. Balfour's repute as a statesman, forget that it ever existed, and apply ourselves to rational and just remedies for the existing state of things.

Notes on Current Topics.

Music and Young Girls.

THE treatment of certain diseased conditions by means of music, as advocated by the too enthusiastic guild of St. Cecilia, does not seem to have made much headway; indeed, there is a sort of reaction against the idea. Some music may possibly have a

soothing influence on the sick, but this could hardly be said of high-class music, such as we are accustomed to hear at fashionable concerts. This involves a strain on the attention which the majority of people find to be positively exhausting, akin to that engendered by too prolonged a visit to a picture gallery. It is not, perhaps, the music *per se* that gives rise to the distress, but the unaccustomed concentration of thought on one subject, the focussing of the perceptive energies in one direction. Music, if too freely indulged in, appears to produce a degree of physical debility in both executant and auditor alike. In the latter the induced fatigue is transitory, but of young women who have adopted music as a profession a large proportion suffer from chlorosis and "nervousness." The physical and mental strain entailed by prolonged devotion to the practice of intricate exercises is admittedly very severe, and this should be borne in mind in determining the fitness of a person with decidedly musical tastes for taking up music as a profession. In this, as in most other professions, success, not to speak of eminence, can only be purchased, other things being equal, at the price of a robust constitution, proof against nervous exhaustion. It goes without saying that sitting out a concert does not produce the same deleterious effects on everybody. Some young girls are obviously benefited by periodical outings of this kind, but these are girls whose passion for music does not carry them away and exhaust their receptivity. While we are hardly prepared to endorse the alarming statements which have of late found currency as to the disturbing effects of addiction to musical pursuits, it may be conceded that girls whose nervous systems are in a state of unstable equilibrium are apt to be unduly fatigued by this form of excitement, and in such cases health must be placed before the mere indulgence of taste.

The Sexual Differences of the Foetal Pelvis.

While the existence of structural differences between the pelves of the male and female adult has long been recognised, the source and method of production of these differences are problems which have occupied the attention of many generations of obstetricians and anatomists. It has generally been assumed that the characteristic features of the female pelvis do not take shape until the period of puberty, and an immense amount of ingenuity has been expended in providing hypothetical explanations of the change. Matthews Duncan, for example, held that the special features of the male pelvis were due to the bones being thicker, stronger, and stouter than in the female, a further factor being their supposed earlier consolidation with each other. This, however, is more of the nature of a statement of appearances than an explanation of their causation, and this observer's theory of the action of natural, *i.e.*, muscular, forces, falls to the ground in view of the fact that such forces must act similarly, if not quite to the same extent, in both sexes. The obscurity which has hitherto surrounded the production of these differences has to a large extent been cleared away by the

painstaking investigations of Professor Thomson, of Oxford, who, in a demonstration at the last meeting of the Obstetrical Society, showed clearly enough, by the aid of numerous beautiful specimens of foetal pelves, that the distinguishing features which serve to identify the pelvis of the male and female respectively are quite well marked as early as the third month of intra-uterine life: It is highly probable, and by no means inconsistent with biology, that these differences exist *ab initio* though this obviously cannot be affirmed owing to the fact that at an earlier date the identification of sex is not possible. None, however, can doubt that a foetus is male or female from the very beginning, though evidence thereof is not as yet available, and it follows that if we could only check the observations the same differences would probably be met with coincidently with the formation of the pelvis as a definite structure. This important contribution marks an epoch in our knowledge of the development of the foetus and will greatly simplify the proper comprehension of the subject.

A Means of Rendering Tobacco Non-Toxic.

IN a recent number of the *St. Louis Medical and Surgical Journal* Dr. Stern calls attention to a procedure recommended some years ago by Professor Gerold, of Halle, but since forgotten, whereby tobacco is divested of the injurious effects due to the presence of nicotine and acrid empyreumatic products. Briefly described, the process is as follows:—fifteen grammes of tannic acid boil in 1,500 grammes of water until the volume is reduced to one kilogramme. Add thirty grammes of the essential oil of origanum vulgare, the solution is then removed from the fire, filtered, and allowed to cool after which it is sprinkled on to eight kilogrammes of tobacco leaves. Dr. Stern has made a number of careful observations with cigars prepared from tobacco thus treated, choosing in preference persons known to have an idiosyncrasy in the direction of intolerance of tobacco, and he invariably noted a complete absence of any of the accustoming unpleasant symptoms, even after three cigars had been smoked consecutively. If, as we are assured, the tobacco thus treated does not lose its characteristic aroma on the one hand nor gain an unexpected flavour on the other, there ought to be a ready sale for the product among our juvenile population at an age when even the now ubiquitous cigarette is apt to give rise to distressing sensations. We fear, however, that the toxic action of tobacco is as essential to the hardened sinner as is alcohol in his beer or champagne. There is nothing essentially attractive in either the taste or odour of the weed, indeed they are drawbacks which are put up with for the sake of the quasi-toxic effects. People do not drink whiskey or absinthe on account of their taste, but in order to obtain certain definite physiological effects, however detrimental these may have been shown to be. There is, however, a certain proportion of non-smokers who are such by reason of their intolerance of tobacco "as she is smoked," and these possibly

may be tempted by the prospect of immunity from undesirable after-effects.

The Axis Traction Forceps in Face Presentations.

PRACTITIONERS are familiar with the fact that when the forceps are applied for the purpose of effecting delivery in complete or incomplete face presentations they usually slip, thus, in many instances of deficient rotation, necessitating recourse to craniotomy. Dr. Lewers has done good service by calling attention to the value of the axis traction forceps under these circumstances, not, of course, in all such abnormal presentations, but when for some reason the head gets jammed and cannot come down far enough into the pelvis for the natural forces to determine rotation. He is careful to point out that it is not so much the axis traction action that overcomes the obstacle, but the fact that it is possible with this instrument to obtain a secure grip of the presenting part, thus enabling the accoucheur to pull down the head into a position where rotation can take place in virtue of the operation of natural forces. As these cases are among the most troublesome with which the obstetric practitioner has to deal he will be grateful to Dr. Lewers for a hint which may prove the means of saving many an infant life if judiciously employed.

The Dangers of Medical Practice in the East-End of London.

WE are not surprised to learn that medical practitioners whose lot is cast in the uninviting districts east of the City are displaying an indisposition to abandon the security of their hearths after dark in view of the frequency with which these ministers of mercy have of late been the victims of violent and unprovoked assault. It is much simpler to decline to expose oneself to this risk than to go about armed because the employment of lethal weapons, even for legitimate self-defence, is certain to entail a large amount of worry and trouble, in addition to much notoriety of an undesirable sort. If the inhabitants suffer in consequence, it will be for them to organise concerted measures to stamp out the gangs of human brutes whose exploits vary the monotony of life in the East End. The police are quasi-powerless unless supported by the public, and the drawbacks of medical practice in such quarters are obvious enough without exposure to unnecessary risks. It had always been understood that medical men were known to, and respected by, these nocturnal marauders, but either this immunity never existed or it has fallen into abeyance.

Hospital Appointments in the Naval Medical Department.

THE Government was taken to task last week in the House for having appointed a Deputy Inspector-General to the charge of the Royal Hospital at Haslar, when the services of no less than three Inspector-Generals were available. The reply, of course, was easy enough. Mr. Goschen stated that he had been

guided, not by seniority or etiquette, but by the desire to select the best man for carrying on of the administration of what he rightly described as one of the most important hospitals in the kingdom. This is a sentiment which cannot fail to command general assent, but we fear that these grandiloquent statements of policy are but too often used as a cloak for favouritism and jobbery. We by no means wish to insinuate that such was the case in respect of the appointment under discussion, though one must sympathise with the three senior officers whose claims to consideration have been so roughly overridden.

The Closing of Metropolitan Hospitals.

THE advent of summer has again rendered it possible for the committees of certain metropolitan hospitals to effect some necessary alterations in their institutions by closing them to patients. This year, however, the closing will be on a colossal scale. In the first place all but a small section of the out-patient department of St. Bartholomew's Hospital will be closed. Again, both King's College Hospital and St. George's Hospital will be entirely closed to all patients; furthermore, the out-patient department of St. Mary's Hospital, Paddington, and the West London Hospital will be closed for about two months. So far as the West London is concerned, the Committee have for long seen the urgency of increasing the accommodation of the out-patient department; at present it is quite inadequate for the needs of the patients who attend, and for the requirements of the post-graduate students. The necessity of proceeding with the enlargement of the departments has lately been strongly represented to the Board of Management by the medical staff, and the result has been that the alterations will be forthwith begun, and will be completed at a cost of £1,500. This will also include a new board room, as provided for in the architect's original scheme of the completed enlargement of the hospital.

The Spectacle Makers' Diploma.

A FEW weeks since the question was raised in these columns as to the attitude of the Ophthalmological Society towards those of its members who allied themselves with the granting of questionable medical diplomas to opticians. We now understand that the learned Society mentioned has decided to take no steps in the matter. That position is to be regretted in a body to which medical men naturally look for an outspoken expression of opinion in the interest both of the profession and of the public. There may be difficulties that render the Ophthalmological Society loath to enter into a public controversy, but that consideration can hardly be pleaded in a matter of internal discipline. In our opinion, the medical profession has a right to ask why a member of the Society is allowed to remain an examiner of the Spectacle Makers' Guild. Curiously, the gentleman in question seems to pose as a kind of expert examiner for lay bodies, for we understand his name appears in that capacity on the rolls of the British Optical Associa-

tion, a title that most of our readers will probably find resounding but obscure. By the way, the arms of the latter distinguished body consist of an ophthalmoscope and two lenses, investing a trial spectacle frame with that supreme simplicity that marks the highest flights of heraldic art. What have the Ophthalmological Society of the United Kingdom to say to the name of one of their members being appended to documents decorated with the foregoing fantastic trades' heraldry? But perchance the spirit of the coming millennium of entire tolerance has descended upon the Council of the Ophthalmological Society.

The "Barker" Anatomical Prizes.

THE Royal College of Surgeons, Ireland, as custodians of this prize, offer for competition a prize of £21, which is open to any student whose name is on the anatomical class list of any school in the United Kingdom. The preparations must be entered before March 31st, 1900. The prize is offered for a dissection of the pharynx from behind, with as many as possible of the nerves, &c., to be found in that region. No prize will be awarded unless sufficient merit be shown, 70 per cent. of the total marks being the minimum. The following is the scale of marks:—(a) For the merit of dissection, 60; (b) for excellence of setting, 20; (c) for originality, 20; total, 100. Those dissections for which prizes are awarded become the property of the College. This prize is awarded by the Curator of the College, the President of the College, and the Professor of Anatomy of the University of Dublin.

The Lay Press Announcement of a "Discovery in Cancer."

IT is stated on the authority of the *Daily Mail* that Dr. Lambert Lack has made a discovery, in the course of exhaustive investigations into the nature of cancer, which is certain to have very far-reaching results. The details of the discovery, we are informed, are not public property, and we are consequently not in a position to arrive at any conclusion as to their value. If it is a fact that the experiments so far have been pronounced by a select committee of the Pathological Society to be practically conclusive; we are not likely to be left long in the dark. The newspaper referred to speaks of the "English doctor's great achievement," and goes so far as to characterise it as "one of the greatest modern discoveries." Supposing this to be the case it strikes us as being somewhat strange that it should be communicated through the medium of the lay press. We learn from the *Medical Directory* that Dr. Lambert Lack is an M.D. of the University of London, and a Fellow of the Royal College of Surgeons of England. We gather, too, that he is an assistant physician to the Hospital for Diseases of the Throat in Golden Square, but we presume that his experiments were not made there. The number of physiological laboratories in London is small, and if his observations were made in one of them we may reasonably expect to receive before

long some official confirmation of such startling news. If Dr. Lack has really made an important discovery bearing on the etiology of cancer, we shall be among the first to congratulate him, but if on the other hand it turns out to be a mere newspaper puff, we shall not be backward in commenting on the somewhat unusual method of publication. Our minds are perfectly open in the matter, and it is for Dr. Lack to establish his contention and make good his claim.

The Ansell Poisoning Case.

SOME of the London newspapers have taken up the case of the unfortunate convict, Mary Ansell, who lies condemned to death for the murder of her sister. For our own part we see no reason to abate the demand we made immediately after the trial for a careful and exhaustive inquiry into the prisoner's mental state. The fact that her sister was an inmate of an asylum at the time of her death gives a clue of great importance in the family history. From other sources we gather that there has been insanity on both sides of the parental stock, and that Mary Ansell herself has shown marked eccentricity during her childish and school days. It is to be hoped that the Home Secretary will not allow any extreme penalty to be inflicted until he has convinced himself upon the most authoritative evidence obtainable that the unfortunate girl Ansell was fully responsible for her acts at the time of the murder. For most medical men the paltriness of the motive and the existence of a family taint would be enough to suggest the exercise of the utmost caution. In a case of this kind should there be a shadow of doubt, we venture to say emphatically that the Crown prerogative of mercy should be exercised without a moment's delay.

The Open-Air Treatment of Consumption in London.

A POPULAR movement is apt to reach a ridiculous stage when it comes to be overdone, and perhaps this criticism may be said to apply to the proposal to carry out the open-air treatment of phthisis in connection with one of the London hospitals for diseases of the chest. It is difficult, for example, to comprehend how the patients will benefit from the inhalation during many hours in the day of a smut-laden atmosphere, such as must be the case wherever such treatment is attempted in London. We do not wish, however, to say a word against the air of the metropolis, which is surprisingly healthy when all things are considered. But, despite its salubrity under general circumstances, we cannot see that to expose hapless consumptives to the continuous inhalation of solid particles of carbon would be especially calculated to improve their pulmonary condition. Better by far that each chest hospital should become affiliated with a sanatorium in the country, to which the phthisical patients could be sent for the outdoor treatment, rather than that valuable time should be wasted in attempting to cure them by following

the treatment in London. The point is really a very important one, because it raises the question whether, in view of the present results of the open-air treatment, provision should not be made for all phthisical Londoners to be drafted off to sanatoria in the country in order to undergo this new method of cure.

Death from Chloroform given for Ablation of Tonsils.

ANOTHER fatality, of a peculiarly regrettable kind, is reported from Winchcombe, where a lad, æt. 15, died under chloroform after removal of the tonsils. We were under the impression that the administration of chloroform for this purpose was generally regarded as undesirable in view of the danger of asphyxia supervening. The verdict of "death from paralysis of the respiratory centre" does not help us much, it is only a paraphrase of "death from want of breath." The question we are called upon to consider is the cause of the respiratory paralysis, and experience, both clinical and experimental, points to the inhalation of too concentrated a vapour as the source and origin of the evil. These deaths, as we are continually pointing out, occur, well nigh without exception, when chloroform is administered in the slipshod fashion still in vogue by the aid of a towel or mask. We are led to ask when will coroners and their juries cease to accept "slightly flabby heart," "respiratory paralysis," and "idiosyncrasy" as affording adequate explanation of what we are fain to regard as, for the most part, absolutely preventible catastrophes. The occurrence of such mishaps when a regulating inhaler is used is almost unknown, thus testifying to the greater safety of this more scientific method of administration. Of course it is possible to kill with such an apparatus, just as it is possible to give a measured but fatal dose of strychnine solution, but the chances of this happening must obviously be vastly lessened.

Sentence on a Blackmailer.

LAST week an exemplary sentence was passed upon a woman at the Lincolnshire Quarter Sessions for a barefaced attempt to blackmail Dr. Davison, of Gossberton. It appears that last May the accused consulted the medical man in question, who gave her some pills. Ten days later her brother-in-law brought the doctor the following letter:—"Sir,—The pills you gave me have done me no good whatever. Unless you send something, and do me some recompense for insulting me in the way you did at your surgery, I shall inform somebody else about it. It ought to be well worth £10 to you for me to say nothing about it. Unless you send the same amount to me, I shall summon you." In the course of evidence, it transpired that the prisoner, in spite of the alleged occurrence, was willing for the doctor to vaccinate her child. The jury found her guilty, and she was sentenced to twelve calendar months' imprisonment with hard labour. Dr. Davison is to be congratulated for his courage and determination in exposing a criminal attempt at intimidation, a base method of attack to

which medical men are peculiarly liable. A few more salutary sentences of the kind passed at Lincoln would make this sort of offender extremely chary of commencing operations. By the way, why was not Dr. Davison a member of the Medical Defence Union?

How Infection is Spread.

DURING the past week several instances have been recorded of the reckless exposure of infectious patients. In one case a father and mother presented themselves at the fever hospital in Belper, Derbyshire, with a child seven months of age, suffering from scarlet fever. They had been staying in a common lodging-house in Alfreton, and apparently resolved to go off straight to Belper without undergoing any such trifling formalities as admission orders and so on. They accordingly went to South Wingfield station and took train to Belper, whither they travelled in a compartment with other people. At Aberdare, four cases of wilful exposure of patients were heard before the local magistrates. In three instances fines were imposed, but the fourth was dismissed, as the bench held the defendant had been misled by the nature of the medical certificate. The practitioner in attendance, so it was explained, had notified the child to be suffering from diphtheria, but had filled in the form "tonsillitis" so as not to alarm the mother, who was in weak health. Such a course can hardly be commended, and any medical man who acted in so unwise a manner would not expect much sympathy if serious complications ensued. It is clear that the whole system of notification would be rendered useless by the exposure of infectious persons.

The Cheerful Doctor.

THE gravity which the public have learned to associate with the attitude of those engaged in practising the healing art is not inconsistent with a certain fund of cheerfulness and good humour. It may be necessary for some men to cultivate a depressing sobriety of verbal and facial expression in order to acquire a reputation of profundity, but the man who knows his work need be under no apprehension lest cheeriness of demeanour should be mistaken for frivolity. Of course, there are times and seasons when a serious demeanour is incumbent upon the doctor under penalty of appearing flippant or heartless, but in general the public appreciate cheerfulness and are grateful for the bright smile and humorous word which, for a brief space, distract the thoughts of the sufferer from the contemplation of his woes. Cheerfulness in the doctor begets confidence in the patient, inasmuch as it is inconsistent with grave apprehensions, and we have it on the authority of Galen that "confidence and hope do more good than physic." The sick are morbidly sensitive to impressions, and the grave face and solemn manners of the melancholic practitioner cannot but give a disastrous turn to his thoughts. Of course it is not given to everyone to be amusing, but we can all be cheerful, and the faculty of interesting one's patients in such a way as to rouse them from the apathy which enforced reclusion entails is

undoubtedly one of considerable value, therefore gaiety short of flippancy and humour apart from triviality are qualities to be cultivated instead of being smothered under the quasi-funereal garb which many medical men still hold to be most appropriate for those the success of whose ministrations is largely dependent on their power of raising the morale of the sick who look to them for comfort and return to health.

THE Committee of University College Hospital, London, announce that the institution will be closed during the month of August, with the exception of the maternity department.

THE annual general meeting of the West London Medico-Chirurgical Society will be held at the West London Hospital on Friday next, at 5 p.m., for the purpose of receiving the annual report and the election of officers and council.

PERSONAL.

MRS. FREDERICK SASSOON has sent a donation of one thousand guineas to the Middlesex Hospital for the Cancer Fund.

MR. E. A. MINCHEN, M.A., Fellow of Merton College, Oxford, has been elected to the Jodrell Professorship of Zoology in University College, London.

MR. WILSON NOBLE, Slieinghurst Grange, Cranbrook, has been elected president of the Röntgen Society, vice Mr. C. W. Mansell Moullin, whose term of office has expired.

MR. W. H. NETHERCLIFT, F.R.C.S.Ed., and Mr. G. M. HIRONS, L.R.C.P., L.R.C.S.Ed., have been appointed magistrates of the Boroughs of Canterbury and Bournemouth respectively.

THE position of Honorary Surgeon to H.M. the Queen, void by the death of Surgeon-General Maclean, has been filled by the appointment of Surgeon-General Colvin Smith, C.B., I.M.S.

DR. WACE CARLIER, Assistant to the Professor of Physiology in the University of Edinburgh, has been appointed to the newly-founded Chair of Physiology at the Mason University, Birmingham.

MR. HERBERT W. PAGE, F.R.C.S., of St. Mary's Hospital, Paddington, and Mr. THOS. R. JESSOP, of Leeds, were elected on Thursday last as members of the Council of the Royal College of Surgeons, England.

DR. JAMES BARR, of Liverpool, has been presented with an address and an honorarium of 150 guineas for past services as honorary secretary of the Lancashire and Cheshire branch of the British Medical Association.

LORD JAMES OF HERFORD was unable, on account of ill-health, to be present at the distribution of prizes to students of Charing Cross Hospital last Wednesday. His place was taken by the Solicitor-General, Mr. Robert Finlay, Q.C., M.P.

MRS. KANTHACK, widow of Dr. A. A. Kanthack, late

Professor of Pathology in the University of Cambridge has been placed on the Civil List for a pension, "in consideration of eminent services rendered to science" by her late husband.

MR. ROBT. S. KINNIE, L.F.P.S., Glasgow, has been presented with a cheque for £250, a silver salver, and a diamond brooch for his wife by the inhabitants of Saltcoats as a souvenir of the completion of fifty years practice among them.

THE many friends of Prof. C. A. Ewald (of Berlin), in this country will be interested to hear that he has recently completed thirty years as a teacher of Medicine, and will cordially join in the congratulations offered to him in Berlin by his friends and colleagues in celebration of the event.

WE are sorry to learn that Sir Thomas Grainger Stewart, Professor of the Practice of Medicine and of Clinical Medicine in the Edinburgh University, is not making such a rapid recovery from his indisposition as was generally hoped for, although he has made considerable progress towards good health latterly.

AT a meeting of the Cancer Society last week, it was resolved to send out Mr. Arthur C. Duffey, M.B., B.Ch., the son of Sir Geo. Fred. Duffey, late president Royal College Physicians, Ireland, to the United States to investigate what is being done in the State Laboratory at Buffalo with regard to the study of cancer.

THE Council of University College, London, has awarded a Research Medal to Dr. S. B. Schryver, of the Wellcome Chemical Research Laboratories, as one of the former pupils of the College who has most distinguished himself in research. Dr. Schryver received the medal at the official presentation of prizes at the College on Friday, June 23rd.

AT a meeting of the Manchester City Council, last Wednesday, it was announced that a "citizen" had offered to build a hospital for consumption, at a cost of £30,000, and to spend an additional £15,000 on the grounds. This is the second generous offer by an anonymous donor to Manchester during the past few months. Although the name of the donor is kept secret, a shrewd guess has been hazarded.

Scotland.

[FROM OUR OWN CORRESPONDENT.]

THE LATE PROFESSOR RUTHERFORD.—On Saturday last a bust of the late Professor of Physiology in the Edinburgh University was unveiled before a crowded assemblage of Professors and Students, in the class-room where he lectured for so long. The bust, which was subscribed for by the medical students of his class, is the work of Mr. John Hutchison, R.S.A., partly from a cast of the late Professor's features, made after death, is an excellent likeness of its subject. Sir William Turner, after Sir William Muir, the venerable Principal of the University, had unveiled the bust, spoke in high appreciation of his late colleague's attainments and merits.

H.R.H. THE PRINCE OF WALES IN EDINBURGH.—The Medical Buildings of the University of Edinburgh were the scene of a notable event on Thursday of last week, when H.R.H. the Prince of Wales was presented by the Lord Provost and Corporation of Edinburgh with

the Freedom of the City in its well-known hall, the McEwan Hall. The day was held as a general holiday from classes, and the function passed off with a maximum of success.

THE ASSISTANT PHYSICIANSHIP IN THE ROYAL INFIRMARY, EDINBURGH, rendered vacant by Professor R. L. C. Leith's translation to Birmingham, is to be filled up next Monday; applications to be lodged before 12 noon, Friday, 14th. The managers have taken a new departure in deciding to limit the number of testimonials sent in by each candidate to six only. The innovation is meritorious, but in this instance rather hastily adopted, especially as so short a time was allowed between notification of the vacancy and application for the post. Six testimonials require almost more care in obtaining and selection than sixty, and delays in acquirement are frequent. It, however, does away with the very considerable volumes which before now have been sent in by applicants for various of the hospital's posts, formed chiefly of a few score letters of credit.

Obituary.

SIR ALEXANDER ARMSTRONG, K.C.B., M.D.

THE news of the death of Sir Alexander Armstrong, late Director-General of the Navy Medical Department, will be read with much regret. He entered the Royal Navy in 1842, but his fame rests chiefly on his personal contribution to the cause of Arctic Exploration. He spent five years in Arctic regions searching for Sir John Franklin's expedition, and he was on the *Investigator* when the North-West Passage was discovered. He has since done much good work in Naval Hospitals in the Mediterranean and in England. He has written his experience in the North and his views on Naval Hygiene. Arctic explorations have advanced much in late years; and Nansen and his compeers are well aware that this advance was only made possible by the stepping-stones laid down by the great explorers of the past.

Sir Alex. Armstrong, who had retired from active service some years since, held the honorary appointment of Hon. Physician to the Queen and H.R.H. the Prince of Wales. His services were further rewarded by Her Majesty with the K.C.B. Trinity College, Dublin, elected him to the honorary distinction of LL.D., and the Royal Society bestowed on him its Fellowship. He also held the M.D.Ed., and the F.R.C.P. of London.

"THE CANCER FOG."

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Dr. Herbert Snow's address at the inaugural meeting of the Cancer Society, printed in your issue of July 5th, tempts me to send you a few remarks. The whole tone and style of the address, coupled with the fascination which the subject has for a long time exercised on me, are my excuse for troubling you; but another motive drives me. I once had, in the dim and distant reaches of the past, some ambition to be a scholar, and in the early days, when what little intellect I had, began to show its bent and direction I found myself driven noticeably in the direction of philosophy and also of logic. Now I see an appeal made in Dr. Snow's address both to the logician and to the philosopher. 'I greatly wish,' he says, "that some competent person would take the trouble to survey, purely from the philosopher's point of view the literature of cancer during the past century." Sir, my practical duties among the surgical and medical therapeutics of cancer for many years past have sadly thwarted any ambition I might once have had to be a philosophical

historian of cancer or of any other literature. But if the philosopher's function be to try to see principles, I have attempted to cultivate that function in the intervals of practical occupation, and the appeal to the logician sounded in this short address presents to my ears a call which I feel myself unable to resist. For such expressions as "constitutional origin, heredity, bacteriological origin, geographical distribution, cancer-houses, damp soils, vegetarianism, electricity," thrown together at haphazard by the writer, as well as others like diathesis, constitution, predisposition, mal-nutrition, hypertrophy, atrophy, ulceration, and the like, have always, since I became slightly acquainted with them, deeply impressed my mind. Now I do not know—I may be wrong, of course—but I rather incline to think that the lament which I see lower down in this address as to "the utter absence of co-ordination and organisation" in our profession is a little confusing in its effect. To appeal, as such a lament does by implication, to co-ordination and organisation is not, I think, quite compatible with the other appeal to the logician, the philosopher, and the philosophical historian which so attracted me in reading the earlier part of the address. I wonder if it will shock you, Sir, if I hint that in my opinion it is not more observations that we require in the study of cancer, but a better use of the observations we already have, if we are to gain any further knowledge of its causes, and therefore of its cure, and especially of its prevention. Surely a total of 24,443 deaths from cancer in 1897 (males 9,573, females 14,870) not to mention the thousands of former years, is sufficient for any man who is in search of materials for observation. "Co-ordination and organisation" would no doubt afford further observations, but when they had been got, what then? and how difficult to get them. How very difficult to get men and women doing the practical work of life to combine in any co-ordinated and organised way to put together new observations which shall promise to be any more instructive than those we have already. I scarcely think that more observations are required. There are plenty already, and the problem regarding them, if by co-ordination and organisation we had obtained them, would still be the very problem that the writer suggests should be grappled with now (or by implication suggests), viz., that we should compare our observations, reflect on them, reason about them, and see if we cannot come to some practical conclusions regarding them. I do not think that a lack of observations is a question with us now almost at all. It is certainly not a burning question. Dr. Snow mentions two respects in which our age differs from its predecessors. Let me mention a third—viz., that the reign of our present gracious Sovereign has been characterised by the accumulation of such a mass of careful and accurate observations as has never been known before. It threatens in fact to overwhelm us. No memory is so prodigious as to be able to carry it, for one is in great danger of failing to see the wood for the trees. It is of comparatively little importance to know that the temperature was 101 deg. F. or 101.5 deg. as compared with knowing that it was high, that it was above normal; or that it was low on the other hand. It is also of comparatively small moment to inquire whether a disease is epitheliomatous or papillomatous, as compared with the question is it hypertrophic or atrophic? And if atrophic, is it directly atrophic, or indirectly atrophic? I am afraid I shock you, Mr. Editor, but I am attempting to follow the most commendable lead in the direction of logical and philosophical inquiry and reflection pointed out by Dr. Snow. Because our ancestors reasoned justly from wrong premises is no reason why we should refrain from reasoning from correct ones. But it is very often assumed that it is. I repeat it; I think careful and accurate observations are not so much a desideratum now as sound reasoning, judgment, and reflection founded on them, and as the attempt to marshal our facts in order and method, and to see the law or laws that govern them, and give them that majestic sweep of orderly succession and methodised arrangement that fill the beholder with awe and wonder and admiration, in place of filling his down-struck imagination with no higher idea than chance, and no nobler conception than

chaos. I do not hesitate to say that I should expect much more benefit to accrue from a collection of observations by Dr. Snow himself, or by any other competent observer, and from logical and philosophical examination of them and reflection on them than from any number of co-ordinated and organised observations such as he suggests. There would be no harm, I daresay, in having both, but let us at least use the observations, alas too numerous, which we already possess, and see what we can learn from them.

Now if in the logical and philosophic and historic spirit which Dr. Snow recommends, we approach the examination of the thousands of cases of cancer in England occurring every year, certain reflections must occur to us. Unfortunately for that logical spirit, and for that philosophic attitude our very terms are not fixed. "Heredity," what does it mean? "Constitutional origin" and constitution itself, what is that? "Bacteriological origin," nay, origin at all, are we agreed as to these? I do not see that we are. But for many years past definitions of some of these expressions have been shaping themselves in my mind, and as Dr. Snow does not enlighten us, I must be pardoned for trying to focus and clear and define myself; which, with your kind permission I hope to attempt to do to some slight extent in my next letter. ♥

I am, Sir, yours truly,

PHILOSOPHUS IGNOTUS.

Laboratory Notes.

"CAFÉ VIERGE."

(Prepared by Messrs. Allen and Hanburys.)

THIS extract holds the first place for excellence among the many coffee preparations we have examined. The manufacturers have succeeded in what is no easy task, namely, in presenting in a concentrated form the characteristic principles for which coffee is valued. In both aroma and flavour "Café Vierge" is greatly superior to most others, and the analytical data given below will convince those who have examined coffee extracts that it is of real value, and contains the soluble constituents of genuine coffee in the true proportions in which they exist.

On analysis we have obtained the following results.—

Moisture	60.22
Mineral matter	4.25
Caffeine	1.98
Nitrogenous matter	4.00
Non-nitrogenous matter (by difference)	29.55

When it is remembered that in many coffee extracts the caffeine is below 0.4 per cent., and even lower, it will be seen that this preparation is of the highest quality.

THE "ALLENBURYS" TOILET SOAP.

(Prepared by Messrs. Allen and Hanburys.)

THIS is a very high-class toilet soap carefully prepared. We have analysed it, and our results are as follows:—

Free fat (by petroleum ether)	2.0 per cent.
Water	...
Soda (as Na ₂ O)	...
Fatty acids	...
Glycerine, &c. (by difference)	9.7

From these results and from the characters of the fatty acids we are enabled to thoroughly endorse the claim of the makers that this soap is prepared from pure fats, and is specially suited for tender and sensitive skins, inasmuch as it contains no free alkali, and is prepared from sweet and wholesome fats.

The percentage of water is remarkably low. That is to say, the purchaser is getting *real soap* for his money, whereas in the case of many common varieties an enormous quantity of water is incorporated by the manufacturer, even though the appearance of the soap may not disclose its presence.

Medical News.

Changes in the Catholic University Medical School, Dublin.

AN advertisement in our issue of to-day states that on October 19th two vacancies in the teaching staff will be filled up. First, that created by the resignation of Dr. James Campbell as Professor of Chemistry. For some time he has had the assistance of Jos. P. Frengley, M.B. Second, the Professorship of Ophthalmology, vacated now by Dr. Louis Warner on the lapse of his period of appointment. He is eligible for re-election.

Guy's Hospital Medical School.

GUY'S HOSPITAL and grounds presented a brilliant spectacle on Friday last, when the annual distribution of prizes was made to the successful students. The treasurer, Mr. Cosmo Bonsor, M.P., presided, and introduced another of the governors, Mr. Robert Gordon, who, besides presenting £1,200 towards the funds of the Medical School, had given a further handsome donation to the hospital during the past year. The latter gentleman then presented the prizes and certificates to the successful competitors. The following were the chief awards:—The Michael Harris Prize for Anatomy: C. H. Robertson. The Woodriddle Memorial Prize for Physiology: J. T. Hicks and A. E. Pakes. The Hilton Prize for Dissections (1898): C. Tessier. The Arthur Durham Prize for Dissections—First year's students: A. M. Webber; Senior students: C. H. Robertson and A. H. Wall. Dental Prizes—Second year's students (1898): P. S. Campkin; First year's students: C. S. Morris. Practical Dentistry Prize: C. S. Morris. Senior Proficiency Prizes: C. T. Hilton, E. B. Dowsett, G. N. Meachen. The Richard Bredin Prize for Clinical Study: R. H. Swan. The Golding—Bird Gold Medal and Scholarship for Sanitary Science: S. Copley. The Treasurer's Gold Medal for Clinical Medicine: G. S. Simpson; and the Treasurer's Gold Medal for Clinical Surgery: C. T. Hilton. This ceremony concluded, the treasurer moved a cordial vote of thanks to Mr. Gordon, which was seconded by Dr. Pye Smith, F.R.S., senior physician, and supported by Dr. Stevenson, senior lecturer in the medical school. With Mr. Gordon's reply the proceedings in the theatre terminated, and a garden party was then held in the picturesque grounds of the hospital, the band of the 2nd Life Guards playing during the afternoon. The hospital and school buildings were thrown open for inspection, many of the large company present availing themselves of the opportunity afforded.

Charing Cross Hospital Medical School.

IN the absence of Lord James of Hereford, Sir Robert Finlay, M.P., the Solicitor-General, distributed the prizes and certificates awarded during the summer session 1898, and the winter session 1898-99, to the student, at the above school, on Wednesday, the 5th inst.

In his report for 1898-99 the Dean (Dr. Montague Murray) announced that the winter session would be opened in October with an introductory lecture by Dr. Mitchell Bruce. He remarked that the school record this year had been one of steady and continuous progress. In 1897 the entries from all sources were 71. This year they were 82, and when the new Hospital Buildings are completed he had no doubt that the increased clinical attractions would result in a still larger number of entries. The New Dental Hospital of London, in which the Charing Cross School was much interested, had also progressed rapidly. Dr. Gallo-way had succeeded Dr. Arkle as Assistant Physician to the Hospital and Vice-Dean to the Medical School. Dr. Hunter had been appointed Lecturer on Practical Medicine and Physician to the Electrical Department, and Dr. Bosanquet had become Medical Tutor. Dr. Eden had been appointed Assistant Obstetric Physician and Tutor in Obstetrics and Gynecology. The Council of the Hospital had instituted the office of Bacteriologist to the Hospital; and to this appointment, as well as that of Lecturer on Bacteriology to the Medical School, Dr. Eyre was unanimously chosen. At the Hospital, Mr. Montgomery had been appointed Resident Medical Officer, and Mr. Daniel, Surgical Registrar.

Royal College of Surgeons of England.

THE following gentlemen having passed the necessary examinations have been admitted Licentiates in Dental Surgery:—

Edward Faulkner Ackery, Henry David Apperly, John Robert Shale Ash, Liston Wheatley Bennett, Alfred Harold Bowkley, Robert Victor Britten, Edward Cardwell, and Harry Whitmore Cutts, Percy Ernest Chandler, Samuel Sydney Doran, Frederick English, Harold Arthur Thomas Fairbank, M.R.C.S. Eng., L.R.C.P. Lond.; Emanuel Bower Marshall Frost, Archibald James Gwatkin, John Walton Gibbons, Edward J. Fabian Gillemand, Robert William Griffin and Cyril Henry Howkiss, Alfred David Hopkins, Ernest Robert Howlett and Arthur Hughes, Harold Samuel Huggins John D. Dawson Humby, Alfred de Betham Jepson, Sydney James Kaye, John Mahoney, De la Hay Moores, Major Percival Nathan, Stephen Holloway Oliver, John Gerdes McAlpin, Herbert William Morris, Percival H. Hayes Palmer, Frank Parlett, William de Courcy Prideaux, Herbert Quinton, Thomas Edward Regan, Alfred Ernest Rowlett, Thomas Francis Ryan, Richard John Russell, Frank Lyon Shelton, Ernest Shrubsole, Sydney Colvin Smith, M.R.C.S. Eng., L.R.C.P. Lond., L.S.A. Lond., Lionel Taylor, Edgar Preston Uttley, Frank Warlow, Eustace B. Lathbury White, John Albert Whittington, Charles Frederick Witcomb, Thomas Herbert Vaughan, and Herbert Gill Williams.

Twenty-eight gentlemen were referred to their professional studies for six months and one for one year.

University of Edinburgh.

THE following candidates have passed the final professional examination for degrees in medicine and surgery:—

Old Regulations.—John Brown, D. B. B. Hughes, Elsie M. Ingles, D. J. M'Adam, Marion B. Marshall, I. J. van der Marwe, A. L. Owen, Eather M. Stuart, Emily C. Thomson, Addie White.
New Regulations.—Ivie Aird, Tina M'ulloch Alexander (with distinction), W. J. Baird, C. A. J. A. Balck, W. J. Barclay, B.A. (with distinction), F. A. F. Barnardo, M.A., E. F. Bashford, J. G. Bell, P. J. Bodington, A. H. W. Boreham, G. A. Brogden, W. J. D. Bromley, E. A. Brown, G. H. J. Brown, Robert Bruce, J. M. Buist, D. A. Callender, H. G. Carlisle, J. C. Carr, Morden Carthew, Lillian Mary Chesney, C. S. Clark, H. E. Coghlan, W. J. Collinson, J. D. Comrie, M.A., B.Sc. (with distinction), B. J. Courtney, R. M. Dalziel, Wm. Darling, M.A., S. M. Dawkins, T. A. Diedjizian, B.A., David Ewart, William Ewart, W. B. Eytton-Williams (with distinction), R. R. Faison, H. Faulkner, David Ferrier, E. G. Ford, A. R. Fordyce, J. J. Galbraith, A. B. George, M.A., H. A. H. Gilmer, B. K. Goldsmith, J. H. Gordon, T. B. Gornall, F. J. Gray, St. L. H. Gribben, A. H. Griffith, George Maddow, P. W. Hampton, F. J. Hathaway, G. G. Hay, A. C. Heath, P. H. Henderson, W. E. Herbert, I. K. Hermon, H. T. Holland (with distinction), A. M. Holmes, James Husband, Alice M. Hutchison, J. G. Jack (with distinction), W. T. James, R. F. Gardin, John Jeffrey, W. J. Jones, J. W. Kerr, D. B. King, M. A., J. D. Laing, I. S. Lessing, T. H. Livingstone, E. A. Loch, J. L. Louis, James Luckhoff, George Lyon (with distinction), Elizabeth G. Macdonald (with distinction), J. M. Macdonald, M.A., P. H. Macdonald, P. N. M. Macdonald, W. J. M'Farlan, John Macgregor, Robina Macgregor, W. M. Mackay, Maxwell MacKellie, H. M. Mackenzie, T. C. Mackenzie, P. A. MacLagan, L. C. MacLagan-Wedderburn, T. D. MacLaren, G. C. M'Leavy, L. W. Macpherson, A. G. Martin, E. W. Martin, J. F. Martin, Ruth Massey, James Masson, M.A., B.Sc. (with distinction), J. W. Matthewson, B.Sc., E. T. Melhuish, E. G. D. Menzies, F. N. Menzies, G. H. Menzies, M.A., James Miller, B.Sc. (with distinction), J. G. Mitchell, H. A. D. Moore, J. B. Munro, J. A. Murray, B.Sc., W. A. Murray, B.A., A. W. Nankevis, A. C. Neethling, T. P. Oates, James Orr, T. S. Orr, William Park, M.A., F. M. Parry, W. M. Paul, M.A., A. S. M. Peebles, E. J. Peill, Arthur Preston (with distinction), T. Price, E. N. Pingle, S. C. Pritchard, J. M. Reid, William Reid, M.A., C. M. Robertson, Thomas Rogerson, R. M. Rowe, M.A. (with distinction), A. B. Shed, Sutherland Simpson, B.Sc., A. B. Slater, V. E. Sopaire, Stephen Southall, H. B. Sprot, Bernard Stracey, W. J. Stuart, M.A. (with distinction), W. W. Thom, G. N. W. Thomas, J. A. Thompson, W. G. Thompson, George Thomson, R. G. Thomson, A. K. Trill, E. B. Turnbull, Alexander Tweedie, C. S. Vartan, N. D. Walker, C. Heron Watson, M.A., C. H. J. Watson (with distinction), Arthur Whitcome, Angus Whyte, A. S. Whytock, M.A., H. D. Wilson, A. H. Wood, and E. M. Young.

Society of Apothecaries of London.

AT the Primary Examination, Part I., held July 5th and 6th, the following candidates passed in:—

Biology.—J. Cretin, G. W. N. Stevens.
Chemistry.—J. Cretin, D. J. Lewis, D. A. Stepney, M. L. Tyler, G. H. Watson, S. H. R. Welch.
Materia Medica and Pharmacy.—C. C. Bernard, G. A. Crowe, A. J. Nicholson, J. R. Pooler, D. W. Purkis, Z. Rowlands, H. M. Sejeant, E. N. L. Wilson.

Preliminary Examination, Part II., held July 3rd, 5th, and 6th. The following candidates passed in:—

Anatomy.—W. H. Cotton, G. M. Crockett, J. C. Curtis, K. A. Dawson, W. C. D'Eath, S. R. Dudley, K. C. Edwards, C. D. E. Forbes, B. H. Hirst, A. H. Hughes, M. E. Martin, T. G. Miles, H. Morrison, D. A. H. Moses, A. J. Parkhurst, C. M. Scott, L. G. Simpson, G. B. S. Soper, C. J. Taylor, C. M. Woods.

Physiology.—C. H. G. Atkins, J. A. Bartlett, C. W. S. Boggs, H. R. Coombes, G. M. Crockett, J. C. Curtis, K. A. Dawson, W. C. D'Eath, K. C. Edwards, B. H. Hirst, A. H. Hughes, J. A. Kilpatrick, J. M. King, M. E. Martin, H. J. May, T. G. Miles, A. C. Parkhurst, G. Raymond, L. G. Simpson, W. A. G. Stevens, R. W. Taylor.

Notices to Correspondents, Short Letters, &c.

✉ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

ACCEPTED PAPERS AND CASES.

THE following are unavoidably held over the present issue, and will appear in due course:—

HEMATURIA FROM HEALTHY KIDNEYS. By Thos. Myles, F.R.C.S. THE DE NOVO ORIGIN OF SYPHILIS. By John A. Shaw-Mackenzie, M.D. Lond.

MONISTIC PHYSIOLOGY. By Wm. R. MacDermott, M.B., T.C.D. CASES OF PROMAINE POISONING FOLLOWING THE INGESTION OF MEAT. By G. Burbridge White, M.D., F.R.C.S.I.

SLEEP, SLEEPLESSNESS, AND HYPNOTICS. Abstract of the Croonian Lecture. By J. B. Bradbury, M.D. Cantab., F.R.C.P. Lond.

THE INNERVATION OF THE HEART. By Prof. von Leyden, M.D. Translation by Wm. Dodd.

SOME RECENT MEDICO-LEGAL CASES. By W. J. Johnston, Barrister-at-Law.

PIREXIA DURING CONVALESCENCE FROM TYPHOID FEVER. By Prof. Potain.

RECOVERY AFTER THE INJECTION OF ANTISTREPTOCOCCUS SERUM. By Skene Keith, M.B., F.R.C.S. Ed.

CHELTENHAM.—In answer to your query, the hot air apparatus mentioned in our note last week on "Hot Air Baths in Work-houses" was Tallerman's. So far as we can learn all other apparatus upon the market are simply variations and imitations of his original patent. The therapeutic value of this form of heat appears to be scientifically established.

LONG v. STOCKER.

WE have received from Dr. Hugh Woods, Hon. Secretary of the London and Counties Medical Protection Society, Limited, a summarised report of the action for alleged malpraxis brought against the defendant, Dr. W. W. Stocker, of Kilburn, by a woman who had been treated by him for an injury to the hand. While we heartily congratulate Dr. Stocker on his successful defence we are unable to discuss the matter for want of sufficiently explicit details in respect of the case for the plaintiff.

G. P.—The taking of snuff has been highly recommended as a valuable means of stopping a persistent hicough, and the act of gargling has also been found very useful.

P. P. B. (Leeds).—Several communications and marked copies of newspapers have reached us referring to the subject of our correspondent's letter, and we shall comment upon the facts in our next issue.

A PARENT.—No sterilising apparatus can be trusted to render contaminated or decomposed milk a healthy article of diet. So-called sterilisation, it is true, will secure the destruction of all living germs, but it does not free the milk from the soluble toxins due to their presence, and such milk, even after sterilisation, is a fertile source of gastro-enteritis in infants. Sterilisation, in other words, may keep fresh milk sweet, but it will not make bad milk good.

R. O. M.—It is much simpler and better to send your specimens to a laboratory for examination and report. Bacteriological research requires much time and no small amount of skill and experience. Failing the latter your conclusions, whatever their tenour, will be untrustworthy. In respect of infectious diseases, many local authorities now undertake to defray the cost of the bacteriological control of the diagnosis.

Vacancies.

Brighton, Hove, and Preston Dispensary (Western Branch and Cottage Hospital), Queen's Road, Brighton.—House Surgeon. Salary £120 per annum, with board and residence.

Coleraine Union.—Medical Officer for the Protestant Dispensary District. Salary £75, exclusive of vaccination and other fees. (See Advt.)

County Asylum, Prestwich, Manchester.—Junior Assistant Medical Officer, unmarried. Salary commencing at £125 per annum, with apartments, board, attendance, and washing.

Durham County Hospital, Durham.—House Surgeon for one year. Salary £100 per annum, and board and lodging.

Fisherton Asylum.—Assistant Medical Officer. Salary commencing at £120 per annum, with board, lodging, and washing. Apply to Dr. Finch, The Asylum, Salisbury.

Govan District Asylum, Crookston, near Paisley, N.B.—Junior Assistant Medical Officer. Salary £100 a year, with furnished rooms, board, laundry, and attendance.

Great Northern Central Hospital, Holloway.—House Surgeon for six months. Salary at the rate of £60 per annum. Board, lodging, and washing provided in the hospital.

Great Yarmouth Hospital.—House Surgeon. Salary £90 per annum, with board and lodging. Wines, spirits, beer, &c., not found.

Liverpool Dispensaries, Moorfields, Liverpool.—Assistant Surgeon, unmarried. Salary £100 per annum, with board and residence.

London County Asylum, Bexley, Kent.—Assistant Medical Officer (male).—Salary £150 per annum, with board, furnished apartments, and washing. Applications to the Clerk, Asylums Committee, 6, Waterloo Place, London.

Lunatic Hospital, The Coppice, Nottingham.—Assistant Medical Officer, unmarried. Salary £150 a year, with apartments, board, attendance, and washing.

Roxburgh District Asylum, Melrose.—Assistant Medical Officer. Salary £100 per annum, with furnished quarters, board, washing, and attendance.

Royal Cornwall Infirmary, Truro.—House Surgeon, unmarried. Salary £120, with furnished apartments, fire, light, and attendance.

St. Pancras and Northern Dispensary, Euston Road, London.—Resident Medical Officer, unmarried. Salary £105 with residence and attendance. Applications to the Hon. Sec., 23, Gordon Street, Gordon Square.

West Sussex County Asylum, Chichester.—Junior Assistant Medical Officer, unmarried. Salary commencing at £100 per annum, with furnished apartments, board, attendance, and washing.

Appointments.

BATTEN, R. W., M.D. Lond., F.R.C.P., Consulting Physician to the General Infirmary and to the Eye Institution at Gloucester.

BUCHER, J. HOWARD, *pro. tem.* Medical Officer and Public Vaccinator for the No. 2 District of the Bodmin Union.

FORSTER, FREDK. C., M.R.C.S., L.R.C.P., House Surgeon to the Royal United Hospital, Bath.

FOSTER, P., M.R.C.S., L.R.C.P., Assistant Resident Medical Officer to the National Hospital for Consumption, Ventnor.

GRIFFITH, A., M.D. Lond., M.D. (State Med.), Medical Officer of Health for the Borough of Hove, Brighton.

HAGH, HAROLD, M.A. Cantab., M.R.C.S., L.R.C.P., Medical Officer to the Convalescent Home, near Huddersfield.

HANLY, JOHN JOSEPH, M.A. R.U.I., L.R.C.P., L.R.C.S. Ed., Medical Officer for the Second District of the Shepton Mallet Union.

HARRIS, H. ELWIN, M.B. Cantab., F.R.C.S., Surgeon to Out-patients at the Bristol Royal Hospital for Sick Children and Women.

HUTCHINSON, F. A. S., L.R.C.P. Lond., M.R.C.S., *pro. tem.* Medical Officer and Public Vaccinator to the Dunmow Union.

LUCY, RICHARD HARMAN, M.A., M.B., F.R.C.S., Honorary Surgeon to the Derbyshire Royal Infirmary.

MARKEY, HERBERT, M.R.C.S., L.R.C.P. Lond., House Surgeon to the Chester General Infirmary.

MORGAN, D. NAUNTON, L.R.C.P. Lond., M.R.C.S., Medical Officer for the new district of Gilfach Goch, Bridgend.

ROBERTSON, WILLIAM, M.D. Glasg., D.P.H., Medical Officer of Health for the Burgh of Paisley.

Births.

BROCK.—On July 6th, at 115, Adelaide Road, London, the wife of J. H. E. Brock, M.D., F.R.C.S., of a daughter.

FALLA.—On July 4th, at Adelaide Lodge Jersey, the wife of Walter Falla, M.R.C.S., L.R.C.P., of a daughter.

SMITH.—At Forres on July 5th, the wife of Colvin B. M. Smith, M.B., of a son.

Marriages.

BALLINGALL-BONNER.—On July 6th, at St. Paul's Church, St. Leonards-on-Sea, George Anderson Ballingall, M.A., M.D., of St. Leonards-on-Sea, and of Altamont, Blairgowrie, N.B., to Mary Lillian Elsie, youngest daughter of the Rev. J. Tillard Bonner, of St. Leonards-on-Sea, late Rector of Stanwick, Northants.

CORFIELD-BURN.—On July 5th, at St. Stephen's, Clapham, Edward Carruthers Corfield, M.R.C.S. Eng., L.R.C.P., and L.S.A. Lond., of Upper Tooting, to Helen Beatrice, only daughter of William Barnett Burn, M.D. Lond., B.Sc. Lond., of Balham.

JENNINGS-TOWARD.—On July 5th, at All Saints' Church, Margaret Street, London, W., R. E. W. Jennings, M.R.C.S., L.R.C.P. Lond., to Eileen, second daughter of the late W. E. Toward, of Newcastle-on-Tyne.

PILCHER SOTHAM.—On July 5th, at the Abbey Church, Shrewsbury, Cecil Westland Pilcher, B.A. Oxon., L.R.C.P., M.R.C.S., son of the late W. J. Pilcher, F.R.C.S., J.P., of Boston, Lincolnshire, to Evelyn Mary, daughter of S. Clement Southam, F.S.A., F.R.G.S., of Shrewsbury.

SHEPHERD-BRUSHFIELD.—On July 6th, at St. Luke's Church, Balham, Timothy Arundel Jordan Shepherd, M.R.C.S.E., L.S.A., of Moldgreen, Huddersfield, to Rosina Mary, eldest daughter of Thomas Nadauld Brushfield, M.D., F.S.A., of Budleigh Salterton, Devon.

WEDD-DRAPER.—On July 1st, at St. James's Church, Blackheath, Gilbert Wedd, M.A., M.D. Cantab., son of John Wedd, of Manchester and Wilmslow, to Bessie, daughter of George Draper, F.R.G.S., Blackheath, London.

Deaths.

CONGREVE.—On July 5th, at Hampstead, Richard Congreve, M.A., Honorary Fellow of Wadham College, Oxford, M.R.C.P. Lond., aged 80.

DAVIES.—On July 3rd, suddenly, at Caswell Bay Hotel, Mumbles, Swansea, Henry Naunton Davies, J.P., Surgeon, of Glyn Rhondda House, Porth, Rhondda Valley, South Wales, aged 71.

FLOWER.—On July 1st, at his residence, Stanhope Gardens, Sir William Henry Flower, F.R.C.S. Eng., K.C.B., aged 67 years.

GIRDLESTONE.—On July 6th, suddenly, at Sunningdale, Berks, T. Mountain Girdlestone, F.R.C.S., late of Melbourne, aged 76.

HEARD.—On July 1st, at Pentre, Hunmanby, Yorkshire, Charles Goodridge Heard, M.R.C.S., L.S.A., aged 47 years, eldest surviving son of Edward Goodridge Heard, J.P., of Truro.

RICHARDS.—On July 5th, at Collyhurst, Manchester, suddenly, Arthur Izod Richards, M.R.C.S., aged 36, younger surviving son of the Rev. G. Richards, D.D., of Ealing.

SLIFFER.—On July 9th, at Brighton, Thomas Clipper, M.R.C.S., L.S.A., of West Croydon, aged 87.

RECOVERY AFTER THE INJECTION

OF

ANTISTREPTOCOCCUS SERUM.

By SKENE KEITH, M.B., F.R.C.S.E.

THE recovery of a patient after the injection of the antistreptococcus serum is still probably of interest to many. In March last I was consulted by an Australian lady, æt. 46, an old patient of my father's, from whom he had removed an ovarian tumour some eighteen years ago. She said that she had been having for some time great monthly losses. On examination the cervix was found to be very hard, deeply lacerated, and slightly irregular on the surface. Visual examination showed a large, torn, and eroded cervix. As I was afraid that the case might be one of commencing malignant disease I asked her to come again. In the meantime she had a period so severe that the loss had to be checked by the injections of hot water. After it was over the cervix was found to be more healthy and softer, and a scraping from the interior of the uterus, examined microscopically, showed simply chronic catarrhal endometritis.

I advised curetting, and Emmet's operation, and performed the two operations on the 2nd of May. Both lips of the cervix were full of cysts, and I had to cut far up into the angles, but did not open into the cellular tissue.

The patient was perfectly well the next evening, but woke next morning feeling chilly. The temperature was 102.6 degs., pulse 120. These attacks, never being more than feeling cold, recurred once every day at gradually lessening intervals, until the sixth day when there were two within twelve hours.

The highest temperature was on the fourth day, viz., 105 degs. in the mouth. Between the attacks the patient felt very well, and the pulse and temperature came down. The "period" came on on the third day, there was no odour whatever.

On the evening of the sixth day the temperature was 103 degs., pulse 160, and the two drugs which had up to that time answered best—antitoxin and strophanthus—seemed to have lost their effect. The patient was evidently going to die, if nothing were done and the only two remaining possibilities were washing out the uterus or injecting the antistreptococcus serum. I was loath to wash out for fear of checking the "period." Instead, the serum, 10 c.c. was injected. The next bad turn was delayed for eighteen hours, it was not so serious as the previous one, 10 c.c. injected again. The patient kept well for sixty hours, when as there was a slight chill, a third injection was made. A fourth injection was given after an interval of eighty-four hours, making much improvement. This, my brother, who had watched the case with me, and I were not much surprised at, as we thought that absorption was now going on from the intestine, and a good result after a dose of calomel strengthened this view.

The life of the patient was undoubtedly saved by these injections, but she might also have lived if the uterus had been washed out, for though there was no

odour while she was very ill, there was a slight offensive discharge for one day at the end of the first fortnight.

While this leaves some doubt still it is certain that the serum saved the patient, and that it was very much safer treatment than washing out would have been under the circumstances.

DECIDUOMA MALIGNUM?

A CRITICAL REVIEW FROM A CASE SUCCESSFULLY TREATED BY

VAGINAL HYSTERECTOMY. (a)

F. W. N. HAULTAIN, M.D., F.R.C.P.E.,

Lecturer in Obstetrics, Edinburgh School of Medicine.

(Concluded from page 31.)

FROM the appearance presented by the specimen before us it must be evident that the term deciduoma is quite untenable. One is therefore constrained to consider whether we have to deal with an entirely different neoplasm from that originally described by Sänger in 1889, the designation of which has been adopted by many other observers, or whether we have to deal with a similar growth whose histogenesis is differently considered. Sänger has depicted (in drawings) cells bearing the spindle-shaped appearance of decidual elements, and there is also shown a slight intercellular fibrillar stroma. At the same time, however, he described large multinucleated protoplasmic masses, which have all the appearance of syncytial origin. If this be so we have a tumour derived from connective tissue (decidua) and epithelium (syncytium); in other words, a mixed sarcoma and carcinoma, which is improbable! Nay, more, if the latest histological descriptions of the origin of the syncytium be right, which I personally, from my own investigations, have no doubt of, viz., that the syncytium is of foetal origin; according to Sänger, we have to deal with not only a mixed tumour as regards structure, but the individual elements are derived from different sources, foetal and maternal. It is possible, therefore, that in Sänger's specimen the so-called decidual elements are merely the cells of Langhan's layer elongated and transformed by pressure, as shown by Teacher in his most able and complete description of a similar condition. Indeed, from the appearances presented by almost all succeeding observers one cannot help but maintain that the cases show a certain uniformity of structure which suggests a coincidence with the appearances presented in my case, whatever their origin may be considered to have been. All the earlier recorded cases suffered from the absence of chorionic villi, and naturally the origin of the cells was more or less hypothetical until Marchand was able (from a case which showed villi with actively proliferating epithelium) to demonstrate the origin of the malignant elements from these epithelial layers. The appearances he demonstrated are identical in every detail with the case I have described.

(a) Paper read and Demonstration given before the British Gynecological Society, June 8th, 1899. For discussion see page 6, No. for July 5, 1899.

Sänger's theory, that the new growth arose from placental tissue, and was a decidual sarcoma, at once gave rise to much discussion and diversity of opinion. The essential characteristic of the neoplasm asserted by him—viz., "that it owed its origin to an immediately pre-existing pregnancy," was at once assailed by some observers who considered the growth to be an ordinary sarcoma. In support of this opinion the following arguments were adduced:—First, pregnancy could not be proved to have pre-existed in each recorded case; secondly, sarcomata of similar structure with multinucleated masses were known to occur, and were demonstrated by Eden and Kanthack from a tumour of the testicle; and, thirdly, the rôle of the malignant cells corresponded with those of a sarcoma in so far as they tended to be disseminated by the blood stream. Each and all of these arguments may be fully met. In the first place, though it cannot be proved that all recorded cases had immediately previously been pregnant, neither can it be proved that they were not, in fact as yet no deciduoma has been described as occurring without the child-bearing period.

As regards the structure of the tumour, though it must be admitted that multinucleated masses are frequently met with in sarcomata, as yet in no other new growth but the deciduoma has there been shown branching reticulated processes of protoplasm as seen in Fig 6.

The rôle of the malignant cells in their dissemination by the blood stream, on first impressions disposes one to consider we have to deal with a growth of connective tissue origin, but if it be borne in mind that the special physiological feature of the chorionic epithelium is to burrow into blood spaces, an extremely strong argument is adduced as to the epithelial prototype of the tumour in question. Further, as has been shown by Teacher, there is undoubted evidence of lymphatic infiltration also. The main upholders of the sarcoma theory have laboured under the disadvantage of not having observed a case with proliferating villi, and have thus had merely the structural appearances of the malignant cells to rely upon; and if, as is well known, it is impossible to distinguish a given embryonic epithelial cell from that of connective tissue origin, arguments from this point of view must be of little value if not upheld by other influences which, so far, are wanting.

Veit, in supporting the sarcomatous origin of the growth, suggests its modification by pregnancy, but brings forward no arguments of weight in support of his theory.

Gottschalk has described the growth as a chorio-sarcoma, and believes it to arise from the stroma of the villi. So far he stands alone. His arguments on behalf of this contention are by no means powerful, and when taken in connection with his drawings and their descriptions do not lead one to seriously consider the hypotheses of much count.

Whitridge Williams has carefully described a case, and considers the growth to be formed by syncytium only. It is possible in his case this may have been so, other observers, such as Nové-Jossierard, and Lacroix, having described similar appearances. I have also noted in certain sections of my tumour a total absence of individual cells where the syncytium alone seemed actively proliferating.

Marchand, Gebhard and others have described tumours in every way identical with my own, and unhesitatingly ascribe the origin of the malignant cells from both layers of the chorionic epithelium. In this Teacher fully coincides, though in his case there was no evidence of villi in the tumour.

With such an array of divided opinions as regards the origin of the growth it is only to be expected that a universally accepted nomenclature is impossible.

The current of opinion of the most recent observers and authors on the subject, with the exception of Veit, seems to be towards its epithelial formation. But, again, a generally accepted nomenclature is frustrated on account of the vexed question of the origin of the syncytium from maternal or foetal structures. According to Gebhard, who believes in the maternal origin of the syncytium, the growth is a mixed carcinoma of maternal and foetal structures; while Marchand, who maintains that both epithelial layers of the villus are foetal, designates the tumour as a chorio-epithelioma. In this latter view I most unhesitatingly acquiesce, and agree with the opinion expressed by Hart and Gulland, and Peters, in their convincing and exhaustive works on the development of the placenta. From personal investigation I have based my opinion on the following grounds:—

1. The absence of syncytium everywhere, except in close relationship to villi, as, for example, its absence on the decidua vera and the decidua lining the uterus in ectopic gestation.

2. Its absence in the intervillous portions of the chorion.

3. The absence of general syncytial change in the glandular epithelioma.

Analogies from demonstrations of its maternal origin from the placenta of lower animals must be considered fallacious, when one recollects not only the absence of uterine menstruation in such, but also the variations in similar types of animals themselves.

The designations of the growth therefore, which to my mind seems most acceptable, are those of Marchand and Kanthack, viz., chorio-epithelioma and trophoblastoma, respectively; a nomenclature which, at least in my case, seems correct and conveys to the mind the true character of the neoplasm.

CLINICAL FEATURES.

From a clinical standpoint the disease may be said to show itself in the majority of instances by the appearance of extremely profuse intermittent uterine hæmorrhages, during the intervals of which there is usually a slight sero-sanguinolent ooze. These symptoms occur in most cases within a few weeks after the gravid uterus has been emptied of its contents, and more particularly should the gestation have been a myxomatous mole. In a few cases (Löhle, Runge, and others) the bleeding has not been noticed for many months after labour or abortion, but it is doubtful whether in these instances the patient had not, in the interval, been again pregnant and cast off an early ovum. As a rule the hæmorrhage is so severe as to reduce the patient to a condition of intense anæmia, and may even be immediately fatal. In due course there is an extremely foetid watery discharge, which may be associated with toxic constitutional symptoms of a septic nature, and give the patient a distinctly cachectic appearance. As the disease advances metastatic deposits may be found in the vagina, cervix, or surrounding pelvic structures, and in many instances death is directly due to pulmonary embolism from the dissemination of the malignant cells through the blood channels.

Naturally, as a disease associated with pregnancy, it is met with only during the child-bearing period of life, a point of considerable importance in the histogenesis of the tumour. A case at the age of 56 is recorded by Meyer, but here an undoubted myxomatous mole was expelled four months previously, and, as is well known, myxoma of the chorion is specially prone to occur in elderly women when sexual activity is on the wane. The youngest case recorded was in a girl of 17, the growth arising from a tubal pregnancy (Marchand). The average age of the cases recorded is 31 years.

In a few cases only has the growth followed a full

time pregnancy, the great majority being noted after abortion and myxomatous chorion. A clinical fact which might be inferred from a study of the histogenesis of the tumour, as it is an accepted fact that in the later months of pregnancy there is little or no activity in the epithelium of the chorion.

FIG. 9.—Pulmonary metastasis from Dr. Teacher's case showing both varieties of cellular elements. (P) Protoplasmic processes. (C) Individual cells.

Diagnosis.—In most instances, as has been shown, there are usually sufficiently early marked symptoms associated with the disease to warrant a suspicion of its presence and indicate a careful investigation. Thus the history of a pre-existing pregnancy (specially a myxomatous mole), followed shortly by profuse intermittent hæmorrhages and a persistent watery discharge, should in all cases demand not only a thorough curettage of the uterine cavity, but a careful microscopic examination of the removed fragments.

Should no evidence of malignant disease be found in the scrapings, and the hæmorrhages return, thorough dilatation of the uterus must at once be carried out, and the cavity explored by the finger. The growth in the earlier stages may be mistaken for an oedematous fibroid nodule but from the fact that it has a friable, ulcerated area which bleeds freely it can be easily distinguished. Portions of the tumour can be detached by the finger nail, and examined microscopically, but this is almost unnecessary, as the presence of the growth is sufficient to warrant a correct diagnosis. Microscopic examination of the scrapings will show large, nucleated cells, and multinucleated protoplasmic masses (Fig. 1), the latter are pathognomonic.

Cases with the marked symptoms recorded offer now no excuse for mistaken diagnosis, recurrent hæmorrhages after curetting must not be temporised with, and repeated curetting is to be earnestly deprecated. Unfortunately, however, there are recorded a few cases in which through the depth of the origin of the growth in the uterine wall, hæmorrhage as a symptom is totally absent, as in the case described by Whitridge Williams, where the first evidence of the disease was metastatic deposits in the vagina and lungs. Early diagnosis of these cases seems to be impossible, there being no uterine or pelvic discomfort to indicate any abnormality. Fortunately such cases are rare, and there are but few in which a prompt diagnosis cannot be made, which is so essential for the efficient treatment of the disease and upon which the patient's life hangs.

Prognosis.—Without treatment of a radical kind the prognosis is absolutely fatal, death occurring in

the majority of instances within six months. By reason of this rapidity it may be considered the most malignant of all known tumours. A few cases have been more chronic in their course, as for example in Löhlein's successful case in which the uterus was not extirpated till more than a year after the symptoms developed. The causes of death are excessive hæmorrhage, septic absorption and the development of metastases, which, in the majority of instances, are pulmonary.

Vaginal metastases are also frequently present. The presence of metastatic deposits, though seriously affecting the chances of the patient's recovery, are not necessarily of fatal moment. Thus, in the cases of Lonnberg-Manheimer and Freund, vaginal deposits were present, yet the patient remained well after hysterectomy. Cazin found a metastasis in the right ovary, yet the patient was well three years after removal of the uterus and ovary.

Even authentic cases have been recorded by Chrobak and Von Franke, where, in spite of evidence of pulmonary embolias shown by hæmorrhagic sputum and other symptoms, complete recovery has eventually taken place. These cases are undoubtedly difficult to understand, but may, I think, be accounted for by the peculiar character of the malignant cells, which, as examination of my tumour clearly showed, grow only in free circulating blood and rapidly degenerate and die in extravasated blood. It is possible, therefore, that the cells in the metastasis may, from giving rise to free extravasations cut off that free circulation which is so essential for their continued activity, and rapidly die. In this way only can Veit's interesting case be accounted where a secondary deposit developed in the right iliac fossa, and eventually disappeared. After complete removal of the uterus, before metastases have formed, the prognosis is distinctly favourable. I have been able to collect 30 recoveries out of the entire 90 cases I can find recorded, many of which were not operated upon.

After complete hysterectomy secondary growths have been known to form, and the patient die six to nine months after the operation as in Morison's case. These have, however, all been operated upon after a long period of temporising in the form of curetting, uterine plugging, and cauterisation. Naturally, the earlier a case is operated on the better the chances of success. There can be little doubt, therefore, that through profiting from the mistakes of others, to whom, as pioneers, we are much indebted, the diagnosis will, as a rule, be much more easily made, and prompt radical measures earlier pursued.

Treatment.—This may be summed up in the word hysterectomy, anything short of this is culpable. Repeated curettings cannot be too severely deprecated as has already been stated when referring to the diagnosis. Many recorded cases are a warning against indecision and delay. These are found among the earlier cases, and are excusable; now, however, with the light of experience, there is no excuse for similar records in future.

I must not conclude without expressing my deep sense of indebtedness to the Edinburgh College of Physicians' Laboratory, where I have been permitted to make these investigations, and from the officials of which I have derived much valued help, and in particular to Mr. Hume Paterson for the accurate micro-photographs he has made.

THE Japanese Government has decreed compulsory vaccination throughout the kingdom. We assume that the local Pooh-Bah will take care of the Japanese conscientious objector.

A COUNTRY HERBALIST'S CURE FOR THE "KING'S EVIL." (a)

By JOHN KNOTT, M.A., M.D., and Dip. Stat. Med. (Univ. Dub.); M.R.C.P.I.; M.R.I.A.; &c., &c.

(Continued from page 34.)

"OF MEDE-SWEET; OR QUEEN OF THE MEDDOWS.

"1. THE NAMES.—It is thought to be unknown to any Ancient Greek or Latine Authors: but later Writers calls it *Ulmaria*, a *foliorum Ulmi Similitudine*, from its likeness to Elme leaves; in English, *Mede-Sweet*, *Meddow-Sweet*, and *Queen of the Meddows*.

"2. THE KINDS.—There are two Species hereof, viz., 1. *Ulmaria Vulgaris*; *Regina Prati Dodonæi*: *Barba*, vel *Barbula Capræ*, or *Barba Caprina Tragi*; *Barba Capri Fuchsi*: *Barbi Capra Lobelii*: *Medesiusium Cordi*, our common *Mede-Sweet*, or *Meddow-Sweet*: some have thought it to be *Rodora Plinii*, but this cannot be positively affirmed: *Tragus* thought it might be *Picnocomon Dioscoridis*, as did also, *Gesner* in *hortis & Lonicæ*. 2. *Ulmaria Major* sive *altera*, *Potentilla Major Prima Anguillæræ*; *Argentina major Thalii*. The Greater *Mede-Sweet*, or *Meddow-Sweet*. *Lugdunensis* says, some took it to be *Melandrum Plinii*, and some call it *Drymopogon*. *Camerarius* says the Germans call the first *Worm-Kraut*, *Worm-Wort*, because, says he, the Root is often found as if it were eaten by Worms: but it is more likely, from its curing Horses of the Botte and Worms, for which purpose the Country people used it.

"THE DESCRIPTIONS.

"3. THE FIRST, OR OUR COMMON MEDE-SWEET.—It has a Root which is somewhat Woody and blackish on the outside, and brownish within, with several greater Strings, and lesser Fibres adjoining; of a strong smell, but nothing so pleasant as the Flowers or Leaves; it perishes not in Winter, but abides many Years, shooting forth anew every Spring. Its stalks are reddish and easy to break, rising to be 3 Feet high, and sometimes to 4 or 5, having at the Joints thereof large winged leaves, standing above one another at Distances; which are made of many somewhat broad Leaves set on each side of a middle Rib, being hard, rough, or rugged, and crumpled much like to Elme Leaves, from whence it took its Name; but having also some smaller leaves with them, like as *Agrimony* has, something deeply dented about the edges, of a sad green color, on the upper side, and greyish underneath; of a pretty sharp smell and taste, very like unto *Burnet*; and will no less give a fine relish to a Glass of Wine, if a few leaves thereof be put therein. At the tops of the Stalks and Branches, stand many tufts of small white Flowers, thrust thick together, which smell much sweeter than the Leaves, which being fallen, in their places come crooked and coloured Seed, crookedly turning or winding one with another, and so making a fine little Head.

"4. THE SECOND, OR GREATER MEDE-SWEET, OR MEDDOW-SWEET.—The Root of this is more woody than the former, with many blackish strings, which smell very strong, and taste somewhat harshly. This Plant grows higher than the former, with longer winged Leaves, set one above another upon the Crested brownish Stalks, having long foot Stalks supporting them; each being usually divided into three parts, the two lowest one against another; and every part also consisting of three or five smaller Leaves than the other, separate each from the other, being hard, crumpled and firmly dented about the edges, at the tops of the Stalks grow the Flowers in

longer Spikes, more sparedly and not so thick thrust together, turning down their Heads, which are white like the former, and smelling very sweet also, more nearly resembling a Goat's Beard (which Name some authors have given to it) than the first kind here described. Gerard says it has leaves of the bigness of Wild Angelica, and grows somewhat after the manner of Wild Angelica; that the stalks are crested and divided into several Branches, which carry long bending Spikes or Ears of white Flowers or Seeds, each single Flower and Seed being something like the former.

"5. THE PLACES.—The first grows in moist Medows which be much wet, or near Watercourses, as the sides of Rivers, and watery Ditches, almost everywhere. The second grows in Woods, Copses, and shady places in Germany and other countries, but here in England, only in Gardens.

"6. THE TIMES.—They are found in Flower through all the three Summer months, viz., June, July, and August, and their Seed is ripe in some short time after.

"7. THE QUALITIES.—Mede-sweet is temperate in respect to heat or cold, but dry in the first Degree. Abstersive, Astringent, and Traumatick or Vulnerary; Cephalick, Neurotick, Stomatick, and Hysterick.

"8. THE SPECIFICATION.—It stops Bleeding and cures Fluxes of the Bowels of all sorts, stops the Whites and Terms in Women, and gives ease in the Colick and Gripings of the Guts. And heals Wounds and old Ulcers.

"9. THE PREPARATION.—You may make from either Flowers, Leaves, or Root, or from all of them. 1. A Liquid Juice. 2. An Essence. 3. A Decoction or Infusion in Wine. 4. A Powder. 5. An Oil. 6. An Ointment or Balsam. 7. A Cataplasm. 8. A Distilled Water. 9. A Spirituous Tincture. 10. An Acid Tincture.

"THE VIRTUES.

"10. THE LIQUID JUICE.—It stops all sorts of Fluxes, Bleedings, and Vomiting, as also the overflowings of the Terms in Women, and the Whites. It is said to alter and take away the fits of Quartane Agues, eases the Gripings of the Guts and moves the Belly downwards. Outwardly applied it heals old Ulcers, which are cancerous or eating, and fills up fistulous or hollow Ulcers with Flesh, and cures Sores in the Mouth and secret parts. Dose from 2 to 6 spoonfuls Morning and Night, or oftner in any Convenient Vehicle.

"11. THE ESSENCE.—It has the Virtues of the Juice, and is more powerful to all the Intentions before specified, and is only to be given from 1 to 3 or 4 Spoonfuls in any proper Liquor, Morning and Night. It is Cordial and very much Cheers the Heart.

"12. THE DECOCTION OR INFUSION IN WINE.—They have the Virtues of the Juice and Essence, but may be given from 2 to 6 or 8 Ounces, sweetened a little with white Sugar: It is very Stomatick, strengthens the Bowels, and causes a good Appetite.

"13.—THE POWDER.—It has the Virtues of the former Preparations, taken from half a Dram to a Dram in any proper Vehicle; if mixt with Honey and taken, it is good against Coughs, Catarrhs, Colds, Wheezings, Hoarseness, Shortness of Breath, and difficulty of breathing. Strewed plentifully upon old, moist, and running Sores and Ulcers, it dries them, and induces a speedy healing; it is also said to kill Worms in Children.

"14. THE OIL BY INSOLATION OR BOILING.—It eases Pains being applied, and strengthens weak Joints, which have been lately Set, or when the Bones have been Broken.

"15. THE OINTMENT OR BALSAM.—It digests,

(a) An abstract of this paper was read in the Medical Section of the Royal Academy of Medicine in Ireland on Nov. 18th, 1898.

cleanses, and induces the healing of old running Sores, putrid Ulcers, Fistula's and the like, and breeds Flesh when it is wanting. Apply'd to parts or Joints pained with the Gout, it eases them.

"16. THE CATAPLASM.—Made of the green Herb and laid upon the Skin, it will in a small time (as Tragus says) raise Blisters thereon. Apply'd immediately to the Biting of a mad Dog, or Stinging of a Scorpion, Hornet, &c., it draws out the Poyson and gives ease.

"17. THE DISTILLED WATER.—It has the Virtues of the Juice, but nothing near so powerfull and being dropt often into the Eyes, it eases their pain, and allays their Heat and Inflammation. It may also serve as a Vehicle to take some of the other Preparations in.

"18. THE SPIRITUOUS TINCTURE.—It is Cordial, strengthens the Stomach and the Bowels, stops Fluxes of all kinds, causes an Appetite and good Digestion, and is profitable against inward Bruises, and gives present ease in the Colick.

"19. THE ACID TINCTURE.—It mightily strengthens the Stomach, and causes a good Appetite, and stops Vomiting tho' of long continuance. It may be taken in all the Patient Drinks, whether Ale, Beer, or Wine, so much at a time as to give the Liquor a pleasing sharpness; and that as well at Meals, as between Meals."

In the year 1735 there was published in Corke a small volume, "*Botanologia Universalis Hibernica*," the work of a western Irishman, J. K'eogh, who was born and educated in the same Shannonside district, and who cultivated the bye-paths of Medicine in the intervals of his professional duties as chaplain to Lord Kingston. This alphabetically arranged treatise contains the following paragraphs:—

"Ordinary Meadow Sorrell, Hib. Saugh boh. Sealgan, and Saveh. Lat. *Acetosa*, vel *Oxalis*. It grows in Corn Fields, and Meadows, flowering in May. The leaves are Antiscorbutic, Cordial, and Styptic, they Refrigerate, quench Thirst, Resist Putrefaction, and are good in Fevers, the seed is put in astringent Medicines.

"Field Sorrel, Sheeps Sorrel, or spear-pointed Sorrel. Hib. *Sauha* Keor-gh or Keirogh, and *Savachyragh*. Lat. *Acetosa Arvensis*. It is like the great Sorrel, but much smaller. It grows in dry barren soil, flowering in May. It has much the same virtues as the former, but not so strong in its operation. It brings to suppuration Imposthumes, and all kinds of Tumours, used inwardly it is Deobstruent, helps the Jaundice and quenbeth Thirst.

"Round Leaved, or Roman Sorrel, Lat. *Acetosa Romana* *Rotundifolia Hortensis*. It grows in gardens, and has the same Virtues and Qualities that the Common Sorrel has.

"Wood Sorrel, Hib. *Samsogy*, *Shamsoge*, Lat. *Acetosella*, *Lujula* and *Trifolium acetosum Vulgare*. It grows in Woody, and shady places, flowering in April. It is more powerful in its medicinal operations than Common Sorrel. It is Cordial, Stomachic, Hepatic, and Hydrotic, good against the Jaundice and Dropsy. It also modifies and heals rotten Ulcers.

"Meadow-Sweet, or Queen of the Meadow, Hib. *Airgid Lovaghra* or *Arigudlugher*, Lat. *Ulmaria* and *Regina Prati*. It grows in moist Meadows, and by River sides, flowering in June. It is Styptic, Alexipharmic, and Diaphoretic. The Decoction or powder of the Roots, stoppeth the Diarrhoea, Dysentery, and all kinds of Fluxes. The flowers in White Wine cure the Tertian Ague. It is also good in Fevers, and malignant Disorders."

(To be continued.)

SLEEP, SLEEPLESSNESS, AND HYPNOTICS. (a)

By JOHN BUCKLEY BRADBURY, M.D. CANTAB.,
Fellow of the College; Downing Professor of Medicine in the University of Cambridge; and Senior Physician to Addenbrooke's Hospital.

THEORIES OF SLEEP.

Those advanced up to the present time may be divided into chemical, histological, vaso motorial, and psychological. These theories are not necessarily antagonistic, as we shall presently see, but their promulgators differ in their mode of explanation and in the prominence which they give to an individual character. Let us first consider the cause of sleep in the abstract.

It is evident that consciousness, whatever this may be, is due to a certain definite condition of the nerve-cells or neurons and any departure from complete consciousness must be due to some change from this state. At the present time it is difficult to come to any other conclusion than that this state and its alterations are of a chemical nature—that consciousness is accompanied by, if not due to, a normal metabolism of the nervous cells, and unconsciousness or diminished consciousness to a chemical alteration in this metabolism. This so-called normal metabolism is the result not merely of the vital requirements of the cells but of this *plus* the alterations produced by the inflow of stimuli. Diminish the stimuli or make them constant both as to kind and intensity (monotony) and the metabolism may become constant though in changed conditions; a kind of acclimatisation occurs, and with it diminished consciousness. The same effect might be produced by the alteration of metabolism due to the application of a poison. It seems to me that the fundamental phenomena to be determined in dealing with psychical processes are the chemical changes occurring in the cells; molecular vibration and processes of a similar nature which have been speculated upon from time to time are, with our present knowledge, in the realms of the unknown. Even if they can be known it seems more philosophical to determine the gross chemical changes first, although there is not much likelihood of these being actually demonstrated in the near future. Admitting that chemical alterations are the causes or proportional concomitants of states of consciousness we shall be able to trace a connection in some of the various theories of sleep which have been propounded. Thus, it is very evident that the metabolism of the cerebral cell may be, and probably will be, altered by changed extrinsic conditions—e.g., by the blood supply—and that it may produce gross physical changes in the cell—e.g., retraction of the protoplasmic processes. The vaso-motorial and histological and in part the chemical theories are—or perhaps it would be better to say may be—thus brought into connection. But let us examine the theories in detail.

The Histological Theory.—The most fascinating of them all is what Duval has termed the *histological theory* of sleep. This seems to have been propounded in its most rudimentary state by Rahl-Rückhard who suggested that an assumed amoeboid motion of the neurons, and especially the dendritic processes, would account for various psychological phenomena. Thus sleep might be explained by a retraction of these processes and consequent inability of nervous impulses to pass from one neuron to another. The same theory was elaborated independently by Lépine and Duval. Lépine thinks this isolation of the individual neurons may be due to some chemical modification of the cellular protoplasm and he also states that the theory explains the extraordinary suddenness with which a state of wakefulness passes into one of sleep. Duval goes so far as to explain the action of medicaments on this theory and he draws comparisons between the action of drugs on the terminal dendritic processes and the effect of curare on motor nerve-endings. This is surely hypothetical. Moreover, he seems to ignore the body of the cell itself; everything is referred to the dendritic terminations. It is most unnecessary to

(a) Abstract of the first Croonian Lecture delivered at the Royal College of Physicians of London on June 20th, 1899.

point out that the theory of Rabi-Rückhard, Lépine, and Duval is dependent upon the conception of isolated neurons as independent units in the composition of the nervous system and that with the disproof of this conception their theory must fall to the ground. Kölliker has strongly criticised this (the amoeboid movement) theory. He says that Widersheim's observations on the movements occurring in the nerve cells of the supra-oesophageal ganglion of *leptodora hyalina* are not pertinent to the question, and he rejects the comparison to the action of curare as irrelevant. Widersheim did not observe movement in the processes of the cells; and in the transparent parts of living animals (the larva of batrachians, the head of the amphioxus, &c.), where nerve terminations have been observed, no movement has been perceived. Moreover, he thinks that if amoeboid movements occur physical conditions would tend to act in a constant manner and the same mental states under varying conditions would be impossible. Furthermore, he says that "it cannot be doubted that the essential function of the nervous system—i.e., psychical processes—is bound up with the nerve cells." In many of his criticisms he seems to me to lay too much stress upon the stability of the axis-cylinder process. The structure of this can hardly be compared with that of the more delicate dendritic processes; and stimuli without influence on the former might powerfully affect the latter. At the termination of his paper he expounds his theory of psychical conditions which although it is necessary to mention is one with which we have long been familiar. The essential factors of mental activity—sensitivity, consciousness, will, &c.—he says, are the nerve cells with their neuro-dendritic processes. These are affected by centripetal stimuli and in turn, through their processes, they act centrifugally on other motor, sensory, or psychical elements. Sometimes the pathway is simple, sometimes extremely complex, and in the latter case the degree of mental gymnastics to which the individual has been subjected is of considerable importance as facilitating the transmission along unusual combinations. He is thus an advocate of the view that facility in thought and action is due to diminished resistance in the pathways, but in what way this occurs he does not state.

Ramón y Cajal strengthens Kölliker's objections by the following. 1. The nerve terminations of the cerebellum, the olfactory bulb, the central auditory ganglion, and the optic lobe constantly show the same extension, form, and degree of approximation to the cell bodies, whatever may have been the mode of death of the animal (from hæmorrhage, chloroform, curare, or strychnine, &c.). 2. The nerve terminations of the retina and optic lobule of reptiles and batrachians (the only animals on which he experimented) show the same condition, whether the organ was hardened after continued rest, as after long retention in the dark, or other activity, as when it had been kept several hours in the sun. He therefore believes that the axites and dendrites possess a constant disposition. But in order to explain sleep and other psychical phenomena he brings in another factor. Under different conditions he found the processes of the neuroglial cells contracted or expanded and he suggests that a function of these cells is to act as an isolating medium between the two neurons. During sleep the neuroglial processes are introduced between the nerve ramifications and the cells or their protoplasmic processes, in consequence of which the passage of impulses is prevented or hindered. Apart from the seat of operation, Ramón y Cajal's theory differs from Duval's in that the processes (neuroglial in the case of Ramón y Cajal) are expanded when the brain is at rest and are contracted when in action. The contraction is usually automatic, but may be brought about by the action of the will. I do not, however, propose to follow Ramón y Cajal in his explanation of psychological phenomena on his theory, especially as his observations have not been confirmed by more recent investigators. His theory seems to me to endow the neuroglial cells with more nervous activity than they are capable of and to allot to them a function which, from their position and structure, I venture to think cannot be maintained. Moreover, if we accept the net-

work theory of Boll, Hill, and others, or Berkley's or Lugaro's modification of the usually accepted view, this explanation loses nearly all its significance.

Before leaving the histological theories of sleep I will briefly refer to a view recently advanced by Gotch to explain the conditions of hypnotism. He goes further than Duval in attributing a major influence to the periphery of the neuron, for he believes that the gaps between the terminations of the adjoining dendritic processes are of primary importance in the transmission of nerve impulses. These gaps determine whether an impulse shall pass or not; once it has passed Gotch believes nothing can hinder its further course. The gaps are capable of variation; in fact, he states that "the whole of modern physiology is inexplicable except on the supposition that the gaps are susceptible of alteration. What this alteration is we do not know; the gap consists of living tissue and, like all living structures, is constantly undergoing molecular change."

The most recent theory has been advanced by Lugaro. According to him unconsciousness is not due to a retraction of the terminal dendritic processes, but to an expansion. As I have already said, he believes that nerve impulses pass through the gemmules and that the passage is facilitated or inhibited by the closer or remoter relation of these to each other. During ordinary thought but few of these are in contiguity, the others are retracted. The latter are in a potential state—that is, they are capable of being approximated by any suitable stimulus. Lugaro's theory differs from that of Lépine and Duval in that expansion of the gemmules is regarded as the resting phase and contraction as the active one. Thus in sleep the gemmules are believed to be expanded, the paths for impulses are thus enormously increased, and this leads to confusion of thought and loss of consciousness.

In the unsettled state of the views of neurologists on the structure of the nervous system it would be impertinent to criticise these histological theories in detail. Further research alone can settle the present conflicting opinions, and on the result of this depends the probability or possibility of the minute changes which we have considered affording an explanation of psychical phenomena.

The vaso-motor theory of sleep is almost as popular as the histological theories which we have considered, and interest in it has recently been awakened by the experiments of Professor Howell of the Johns Hopkins University. It has, however, been a favourite theory for many years. Based upon direct observation of the cerebral cortex by Donders, Durham, Hammond, and others, and on the plethysmographic researches of Mosso, it seemed to possess a firm foundation, but of late this has been rudely shaken. The conditions of experimentation in these researches were not normal, and further investigations have shown the necessity of modifying our views on the matter. Thus Dr. Leonard Hill has proved that practically no change occurs in the cranial contents, that the brain at nearly all points is in contact with the cranial wall, and that the amount of cerebro-spinal fluid in the intact cavity is very small and incapable of gravitating to any appreciable extent into the spinal canal. Moreover, he has shown that the cerebro-spinal pressure equals the venous pressure, that it does not rise beyond it, and that the cerebro-spinal fluid does not normally function as a compensating mechanism for alterations in the cranial contents. "The volume of the blood in the brain," he says, "is in all physiological conditions but slightly variable." Therefore, cerebral anæmia, if we regard this as a diminution in the total quantity of blood in the brain, cannot exist to any extent. It is possible for an arterial anæmia, combined with venous congestion, to occur, and Dr. Hughlings Jackson's observations on the retinal vessels during sleep would render this not improbable. In view of Dr. Leonard Hill's researches it seems absolutely necessary to recognise the Munro-Kellie doctrine (the incompressibility of the brain and constant volume of the cerebral contents) in dealing with the causal factors of sleep. Cappie, on purely theoretical grounds, advocated this doctrine, and advanced a theory of sleep in harmony with it. The main feature of his view is that the arterial

anæmia of the brain is compensated by a filling of the pial vessels and an alteration of the normal pressure on the cerebral surface from an expansive to a compressive force.

Since Dr. Leonard Hill's investigations Professor Howell has advanced a modified form of the vaso-motor theory based upon personal experiments. According to him the anæmia of the cortex is counterbalanced by the dilatation of the vessels at the base of the brain. The causal factor of sleep is a fatigue of the vaso-motor centre, and particularly of that part of it supplying the skin area. This Professor Howell deduces from the fact that the volume of the arm increases (that is, the cutaneous blood-vessels dilate) just previously to sleep, and it usually contracts suddenly on awaking. He does not, however, ascribe the production of sleep solely to the fall of blood pressure, but he regards this as pre-eminent. The etiological factors he gives as follows:—1. A diminution of irritability caused by fatigue of large portions of the cortical area. 2. Voluntary withdrawal of sensory and mental stimuli involved in the preparations for sleep. 3. A diminished blood-supply to the brain owing to a relaxation of tone in the vaso-motor centres and the fall of general arterial pressure thereby produced. Recently Dr. Leonard Hill has criticised Professor Howell's results, or rather his deductions from his results. He finds that the fall of arterial pressure is concomitant with sleep, and he adduces confirmatory experiments. Thus he found arterial pressure "as low when lying in bed in the waking state in the morning as in the sleepy state in the evening"—a result evidently antagonistic to Professor Howell's theory. Moreover, it is not difficult to explain the fall of blood-pressure during sleep, or even previously to sleep, by the posture, the diminution of external stimuli, the extra clothing, &c., which we seek before endeavouring to sleep. The rapid rise of blood-pressure at the moment of awaking Dr. Leonard Hill explains thus:—"As the waking state is neared the turgescence of the limbs is lessened owing to the increased tone of the muscles and to the restlessness of the sleeper. Each movement or deep respiration expresses the blood and produces a lessening in the volume of the arm. This is shown to be so by an examination of Howell's tracings. Since each movement of the body momentarily raises the vena-cava pressure the brain is congested thereby, for the cerebral circulation passively follows every change in vena-cava pressure. The flushing of the brain is secondary to the external stimuli which provoke the external movements of the body, accelerate the heart, and increase the vaso-motor tone. At the same time these stimuli may awaken the dormant consciousness. Carefully reviewing all the above facts we must, I think, conclude that the anæmia of the brain is caused by rest of the body and the cessation of powerful objective and subjective stimuli. It is the cessation of the latter that produces sleep."

Chemical Theories—The various chemical theories which have been put forward seem to have been based on insufficient data. With the older theories of Sommer and Pfleger and others I do not intend to deal. But comparatively recently a new chemical theory has been advanced. Errera believed that the leucomaines produced by the normal activity of the body play a predominant part. He has based his view mainly on the experiments of Bouchard and his school, who found that during the night convulsant substances were excreted in the urine which were not present during the day. The toxicity of the urine during sleep was found to be much less than that of the urine passed whilst awake. On these experiments Bouchard formulated the theory that during the day the body formed a hypnotic substance which by its accumulation produced sleep and that during sleep a convulsant substance was formed which by inducing muscular movements produced awakening. Both Beck and Herringham have failed to corroborate Bouchard's experiments, but apart from this it is difficult from evidence of this kind to draw conclusions as to the cause of sleep. The urine is a complex body, it varies largely in composition with the kind of food, the amount of exercise, and other physiological and pathological conditions, and this variation is greater

with this than with other secretion. It does not seem right to compare the variability of the composition of the urine with the periodic alterations in the temperature and pulse; the limits of the first are much wider. Furthermore, as in the case of blood-pressure, it does not seem to me proved that this altered composition of the urine is not *post* rather than *propter*. I do not mean to imply that metabolic changes have no influence in the production of sleep, but what I do maintain is that sleep has not been proved to be due to any one substance or group of substances present in the urine. The chemical theory from another point of view I shall mention presently.

The Psychological Theory.—The fourth class of our division of the theories of sleep is the *psychological*. And here we enter upon difficult ground. We have seen that the physiological and psychological are two separate spheres with independent methods of analysis, that the elements of the two sciences are different, and that the connection between the two can only be one of parallelism. It may be that we shall never get beyond this stage—that the physical and the psychical even in their simplest forms are not comparable, but from a physiological point of view there seems nothing improbable in the idea that they may be correlated. Maria de Manacine, in a popular book on sleep published two years ago, defines sleep as "the resting time of consciousness," and perhaps from a psychological point of view no better definition could be given; but to me it is a mere statement of a psychological fact, not an explanation. We cannot account for sleep in such an immaterial manner. We may not be able, perhaps, to give any further explanation at present, but the acceptance of such a theory would deprive us of that most valuable aid to research, a working hypothesis. It is not improbable that the new schools of psychological physiology, and especially those which deal with it from the pharmacological side, may help us to a truer conception of the causes of sleep. Wundt and his pupils have already added something in this direction, and it is especially to his pupil Kraepelin that much of our knowledge in this department is due. In a recent paper from his laboratory a new explanation of the action of hypnotics is given. Working on the psychical influence of trional with Kraepelin's methods Hans Haenel found it to diminish the power of calculating and learning by heart, to increase the time in the choice-reaction, to diminish the erroneous reactions, to increase faults and omissions in reading and apprehension, and to diminish the rapidity of writing. He found it, however, to exert no influence on association and muscular work (ergographic curves) nor on the rapidity of repeating things previously learnt. The hypnotic action of the drug is explained, Haenel says, by the depression of apprehension and the increased difficulty in originating co-ordinate movements. He draws attention to the fact that these, and especially diminished power of apprehension, are present after all hypnotic drugs have been given, and the fact that morphine is not regarded as a hypnotic in small doses is due to the stimulant rather than to the depressing effect which it exerts on psychical processes. This in psychological terms is the condition produced by the action of hypnotics, but as an explanation of sleep it is not sufficient.

If, then, we feel obliged to discard psychological explanations—and with due deference we must do this—we can only return to physical and biological science. As we have said, the fundamental changes must be in the neurons themselves. I am inclined to believe that these are primarily of a chemical character. The differences observed between rest and activity and the changes resulting from the administration of various poisons, I think, support this view. But these differences are in no sense crucial. Before we could consider them such it would be necessary to know for certain what cells are concerned in the production of mental phenomena and what changes result from the action of hypnotic drugs upon them. The action of poisons on nerve-cells generally is, however, at least suggestive, as it shows that marked changes of a more or less transient character may occur during life. As many years ago as the year 1876 W. Ludwig, a pupil of Binz, described changes in the nerve-cells of excised and

teased cerebral tissue after the application of hypnotics, and came to the conclusion that these, even when well diluted, produce a kind of coagulation of the albumin of the nerve-cells which is not produced by other and closely allied bodies devoid of hypnotic powers. A year later Binz himself described the effect of morphine on isolated nerve-cells. After a time a kind of coagulation-necrosis was produced, which did not occur after the application of atropine or cocaine. Strychnine and quinine, however, produced the same effect, so that the action is not limited to hypnotics. More recently the action of poisons has been investigated by means of Nissl's method, and a great number, including many metals, alkaloids, and toxins, have been found to produce distinct changes. Nissl believes that this action is characteristic for the same poison and the same kind of cell, but as yet there is a want of unanimity on this point. That decided morphological changes may be produced by the action of poisons all are agreed, and that these changes may be rapidly produced has been shown by Goldscheider and Flatau in some recent interesting researches. The function of Nissl's bodies is unknown, and their existence under normal conditions has even been doubted. From investigations by Nissl's method, however, there can be no doubt that visible changes, often of a very marked kind, are produced in nerve-cells by the action of poisons, and these we can only regard as of a chemical nature. Changes, too, are produced in the dendritic terminations of the cells, and usually these appear earlier and are more marked than those in the cell-body. But in the dendrites more than in the cell observers differ as to the exact conditions present. Thus after the administration of morphine Demoor describes nodosities on the dendrites which in extreme cases are reduced to mere moniliform filaments, while Lugaro observed expansion of the gemmules and very slight thickening of the processes. Alterations of the dendrites have been noticed by various observers after hypnotic drugs, and there can be little doubt that transmission of nerve impulses through these must thereby be markedly retarded, if not prevented.

Owing to the differences of opinion of observers regarding the exact condition produced by hypnotic drugs it is impossible to draw a satisfactory conclusion regarding their mode of action or the cause of sleep. I am inclined to believe that hypnotics act chemically upon the neurons both upon the cell-bodies and their dendrites, and I think histological observations support this view. Retraction of the terminal processes or gemmules, if such occur, I believe to be secondary. But what part is played by the cell-body and what by the terminal processes it is difficult to say. The finer dendrites are probably more exposed to external influences, and any modifications in them must affect the transmission of nerve impulses, but the cell-body is the seat of metabolic activity, and this, too, must be readily affected by changes in the environment. At the present time there is a tendency to regard the functions of the cell-body as purely nutritive, but, although this may be the case with such cells as those of the posterior root ganglia, it is probably not the case with the cortical cells of the brain or even with the cells of the spinal cord. But a discussion of this would lead us too far afield, and in the end we should have once more to confess our ignorance. Lugaro's view of the action of hypnotics and the cause of sleep I have already noticed. Demoor, as a result of his histological researches, desists from any attempt to formulate a theory of sleep. "Regular and periodic sleep, like the sleep produced by chloroform and morphine, and the inactivity succeeding exaggerated work, finds," he thinks, "its application in part of the facts studied in this work," but the cause of the appearance of sleep he "lays aside, like many others, without a solution," and as regards its intimate nature we with little more knowledge must do likewise.

THE old established firm of Weiss, the surgical instrument makers, has been converted into a company, with a capital of £10,000.

Transactions of Societies.

ROYAL ACADEMY OF MEDICINE IN IRELAND. SECTION OF ANATOMY AND PHYSIOLOGY. MEETING HELD FRIDAY, JUNE 2ND, 1899.

The President, Dr. D. J. COFFEY, in the Chair.

DISTRIBUTION OF THE GLANDS IN THE HUMAN ŒSOPHAGUS.

THE PRESIDENT (Professor Coffey) said that the œsophagus, after fixation and hardening, was divided into twelve segments of equal length, and then sectioned. The glands appeared isolated; they were large enough to be distinctly visible to the naked eye, and lay imbedded in a fairly close-textured fibrous submucosa. Each one was formed of a close cluster of alveoli, lying a short distance below a well-defined continuous and rather broad band of muscularis mucosæ. Sometimes a detached strip of this muscular layer extended below the gland. In the transverse section, of which a complete set had not yet been made, the glands occurred in interrupted vertical rows. The whole arrangement contrasted remarkably with the thick, almost unbroken stratum of glands which occupied the whole submucosa in the dog. The number of glands in any one vertical section through the whole length of the tube was about thirteen as a rule. They were placed in the successive segments, in the following order from above down—three in the upper four segments, four in the next two, the succeeding two segments were devoid of glands, then followed four glands, and lastly, two in the remaining segments. The examination of the junction of the tube with the stomach was as yet unfinished. The upper half of the mucous membrane was therefore better supplied with glands than the lower half. Other features of the histological structure investigated showed that the unstriped muscle in the circular coat extended almost to the upper extremity of the tube.

THE HISTOLOGY OF THE HUMAN VERMIFORM APPENDIX.

THE PRESIDENT said that the general arrangement and structure of the layers of the tube corresponds with that of the large intestine. The muscular layers are, however, pretty thick for a tube of such dimensions, the external or longitudinal being complete, and containing almost as many rows of cells as the circular layer. Most interest attaches to the submucous coat. It is almost wholly occupied by lymphoid nodules arranged in a thick ring. Each one is conical in form, base outwards, and surrounded by a capsule lined with endothelial cells, which thus constitute a lymph sinus drained by the lymphatic. The solitary follicles, which in the intestine lie mainly in the mucosa, are here crushed out into the submucosa altogether. This determines a condensation of the proper areolar constituents of this layer into a band of dense fibrous tissue, lying outside the nodules and separating them from the muscular wall. One or two thick bands, however, remain in the radial direction, and run inwards from the muscular to the mucous coat. The lymphoid nodules vary much in size, and a few large ones appear to be projected inwards from the ring, invading the mucous coat and reaching to the epithelial surface. These differ in shape from the submucous nodules, being pyriform, with the broad end inwards. They might be described as a sort of second ring pushed inwards from the crowded outer set. The want of uniformity in the size of the nodules is apparently associated with the irregularity of the lumen of the tube. The glands of the mucous coat are of the normal character and are fairly numerous. The muscularis mucosæ is thin and badly defined, it is broken into strips and lies immediately internal to the apices of the conical lymphoid nodules.

Professor PURSER said that the finding of unstriped muscular tissue so high up in the œsophagus was very interesting, and a new fact to him. He had often in examining pathological specimens been struck with the absence of glands in the œsophagus, but that may have been owing to the pathological condition. The distribution of lymphoid tissue in the vermiform appendix was

very interesting; in the rabbit it was the rule that two or three layers of adenoid tissue were present lying over each other.

Professor BIRMINGHAM said that a striking picture of the structure of the appendix was given in Testut's "Anatomy," but it represented the muscularis mucosæ as lying outside the lymphoid structures. Evidently the true muscularis mucosæ, which is very faint, was overlooked.

THE FORM AND POSITION OF THE THORACIC AND ABDOMINAL ORGANS IN THE LEMUR.

Dr. C. J. PATTEN read a paper on this subject. The communication was illustrated with lantern slides, and dealt more especially with the relations of the viscera to the vertebral column in the lemur as compared with some other animals. The value of the method of preserving and hardening the viscera with formalin was indicated, and the form which most of the solid organs assumed was brought out.

The PRESIDENT remarked that the methods of classifying vertebrate types came to little more than dentition, and some few features about bones, with most meagre facts about viscera. Regarding lemurs, which are so doubtful in position, it was very useful to show exactly the relations of their organs, and Dr. Patten's work was very carefully done in this respect.

Professor D. J. CUNNINGHAM said that Dr. Patten's work was most carefully done. It was another evidence of the value of formalin. It was very unsafe to found any classification on one or two characters. The animal must be investigated from top to toe, and recently, even the muscles which had been thrown into disregard for a long time, are being utilised for this purpose.

SERIAL SECTION OF THE ADULT HUMAN BODY MADE WITHOUT FREEZING.

Professor FRAZER exhibited serial sections of the entire head and neck, several from the thoracic region, and the entire lower limb, from a subject which he had cut in the transverse vertical direction, and serially at intervals of about one inch, from the crown of the head to the soles of the feet. The subject had been injected from the femoral artery with a modified formalin solution under a pressure of about eight feet; it had then remained exposed to the air without covering in the preparation room, when it was removed to the dissecting room, and cut serially at intervals with an ordinary amputating knife, and a small saw without a back, the latter being applied to the bone wherever that became necessary. The sections were perfect, both as regards the hardening and the colour of the various tissues, and could be used with great freedom. They could be handed round the class, and examined by each member; they could be left exposed to the air for days; they could be left under water also for days, or they could be finally mounted in a preservative fluid. It was desirable to have an alternative method of making useful and instructive serial sections of the adult to that which had hitherto been employed, which was the ordinary mixtures of ice and salt, or snow and salt, in the absence of proper refrigerating chambers, which were not, as a rule, attached to anatomical departments in Great Britain or Ireland. The meeting could say whether the sections now exhibited would not bear favourable comparison with any that had ever been made by the method of freezing.

The PRESIDENT said that the sections were of great value for teaching purposes, and showed the natural appearances very well.

Professor BIRMINGHAM complimented Professor Frazer on the beauty and usefulness of the specimens.

Professor BIRMINGHAM exhibited a formalin specimen of the abdomen, prepared to show the lines of reflection of the peritoneum.

This was the last meeting of the Session.

SIR J. CRICHTON BROWNE, M.D., F.R.S., has promised to deliver the introductory address at the opening of the winter session in the medical department of Owens College, Manchester, on Monday, October 2nd.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, July 15th, 1899.

At the Society for Psychiatry, Hr. Henneberg showed preparations illustrating a

CONDITION OF THE SPINAL CORD IN CHRONIC NEPHRITIS.

Two preparations were shown. In one there were smaller and larger sclerotic patches. In one place softening of the grey matter had taken place, which was a rare occurrence in the spinal column. There was a complication of patchy disease with systematic degeneration of the columns. Both were dependent on the same etiological condition, distinct disease of the vessels. In the second case this was not so widespread. There were both ascending and descending degenerations. All the diseases were due to disease of the vessels, which had set up disturbances of circulation.

Hr. Oppenheim considers the significance of the changes as correctly given, the changes in the vessels played the leading rôle. Such conditions were met with even in arteriosclerosis. He had also seen similar changes in a case of chronic lead poisoning.

Hr. Goldscheider confirmed the rôle of the blood vessels in disease of the cord. The cases brought forward he held to be contracted kidney. He had diagnosed clinically a case of nervous disease in a case of arteriosclerosis. The symmetrical disease of the long tracts was interesting; it was doubtful if this had any connection with the nephritis. In Bright's disease the cerebral symptoms predominated over the spinal.

At the Medical Congress Hr. Escherich, Gratz, read a communication on

BACTERIUM COLI.

He had never seen production of gas in decomposition of albumen by bacterium coli. The bacilli present in stools were not an heterogeneous mixture with those introduced into the intestines with the food. The bacterium coli from even normal stools had pronounced toxic and infection properties. But an organism that could harbour those numerous poison-forming bacteria without injury had been supposed by some authors to possess auto-immunising properties as they protected it against the invasion of toxins. He considered this hypothesis as unlikely, also on his own investigation. He was opposed to the view that the pathogenic action of the bacterium coli could be exercised from the intestinal canal. He believed that infection must be caused by the entrance of virulent coli bacilli from without. Quite lately it had been held that dysentery was caused by a bacillus similar to the bacterium coli and the serum reaction had been made. In a house infection it had been observed that the nurses were attacked by dysentery-like symptoms. The word dysentery was now a comprehensive term for a large number of diseases.

Hr. Jacobi, Berlin, reported on a case of typhoid in Gerhardt's klinik, in which an attack of pneumonia came on, in the sputum of which the bacterium coli was found.

Hr. Gans, Carlsbad, said that 2 to 4 days' pure cultures of bacterium coli increased the sulphuric ether considerably without any indication of indican; 4 to 7 days' cultivation of the proteus vulgaris increased the excretion of indican. Once the sulphuric ether was nominally

increased, another time it was absent; 2 to 4 days' cultures of bacterium acidilactia sometimes increased the ether and sometimes not. Indican was not excreted. Ten grammes of yeast suspended in 200 of water caused excretion of indican without influencing the sulphuric ether.

Hr. Pribram discussed the

INTERMITTING ALBUMINURIA OF ADOLESCENTS.

It was a striking fact that frequently in youthful and normal individuals at some parts of the day albumen might be found in the urine, and especially after bodily exertions. There were variations in this tendency. Movements of the upper extremities generally had less influence, for example, being less in violin playing excepting when the player stood. If such cases were observed long enough, it would be seen that with the intermitting growth of the youthful body the tendency diminished and increased in the periods when growing persons began to make awkward movements, got large hands and feet, and gradually disappeared when the lengthening of the body made them of adequate size. How far the albuminuria was physiological was undecided. Cylindruria was not observed for years. In one case severe scarlatina was not followed by nephritis. With proper treatment and gradually developed movements, no albumen was traceable even after dancing, tennis playing, &c.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, July 15th, 1899.

IMMUNITY.

THIS obscure subject was again the object of discussion at the annual meeting of the Bohemian "Verein." Pelnar introduced it with a review of its past history. Every advocate and partizan, he said, had ample scope for dogmatizing and speculation in this department of medicine owing to our very great ignorance of the whole subject, apart from a few empirical results, which had often as many exceptions as cases that conform to any rule. The different forms of immunity may be briefly enumerated—hereditary, acquired, congenital, previous attack, vaccination, toxin injections (active), and serum injections (passive immunity). There may be added to this list the bacterial immunity and the bacterial product or toxin immunity.

The hereditary or congenital immunity is clearly demonstrated *in vitro* by Metschnikoff's experiments, where the infected body can be seen defending itself against the invader. The bactericidal property resides in the blood, probably in the serum, as recently confirmed by the experiments of Swatschenko.

The antidote theory assumes a natural protecting property on the part of the organism, which we are not yet in a position to prove beyond empiricism, but it is believed that all vital tissues have a self-resistance peculiar to the organism, although different parts have more resistance than others, as, for example, rats are quite immune against the toxin of tetanus from external causes, yet when injected so as to act on the nerve centres the poison acts violently, according to the testimony of Roux and Borrel.

Hereditary immunity is supposed to be transmitted by the blood, or milk of the mother, in the form of a

paralysing substance that has not been isolated, but the effect whereof has received the happy appellation of "passive immunity."

The artificial methods are by means of living or dead cultures, or extracts of the dead cultures termed "plus-minen." These in recent years have been much criticised, sometimes praised as potent agencies, at other times totally discredited. It is admitted that a large number of phenomena have been produced by these artificial preparations, but none can demonstrate to our satisfaction that the bactericidal action, "agglutination" power, or the bacteriolyses of Pfeiffer will prove a potent immuniser. The same may be said of these as preventives, so that sero-immunisation and serotherapy are not yet rational methods of treatment. The minimal dose theory is equally unreliable, as a lethal dose must be given to immunise, although some few cases on record would seem to point to good results.

He next entered into a long criticism of Kruse's modified "Retention" theory, Wassemann's "Seitenketten-Immunität," and Centani's "Stomo-oisinen-theorie," all of which he asserted were absolute failures.

MYXÆDEMA.

At the same meeting Prochaska exhibited a young male dwarf, æt. 20, who had every appearance of infantile myxœdema. There was no history of heredity; he was late in walking, his first teeth appearing when three years of age, and is quite idiotic. His somatic appearances before treatment was commenced are described as follows:—Height 101 centimetres (39·76 inches), cranium asymmetrical, sutures irregular, features distinctly cretin-physiognomy with macroglossia, the gums thick, pharyngeal mucous membrane swollen, and the teeth carious. By palpation the thyroid cannot be distinguished. The body short, skin distinctly thickened by myxomatous infiltration of the deep cells. In the clavicular and axillary regions were tumours about the size of the fist, and the abdomen showed an umbilical hernia. Temperature averaged about 98·8 degs.; daily quantity of urine passed 1,000 grms.; number of erythrocytes three millions; weight of body 28·4 kilos or 62·48 lbs. After eleven weeks treatment with thyroid tabloids, each containing 0·10 gramme = 1·5 grains of the thyroid substance, the following condition was observed:—Macroglossia had disappeared along with the infiltration of the skin and the swellings in the clavicular and axillary regions. The previously subnormal temperature rose one degree, while the number of pulsations and diuresis were distinctly increased. During the period of treatment the patient grew 3 ctm. in length, and distinctly improved in intelligence, spoke more, was active in movements, and ate and drank heartily, while the body weight increased 6 kilogrammes—13·2 lbs.—in the same period. No bad effects were observed throughout.

He concluded by reviewing the collateral changes, and was convinced of the efficacy of the thyroid therapy.

A MURAL tablet has been placed in the main reading-room of the Edinburgh University Union. It bears the following inscription:—"In memory of James Robert Hunter, M.A., who died January 24th, 1899, during the term of his Presidency of the Union. This brass, and the set of volumes in the library known as the 'Hunter Memorial,' were subscribed for by his many friends in the University."

Continental Notes.

SUMMER SAUNTERINGS IN VALAISAN VALLEYS.

[FROM OUR OWN CORRESPONDENT.]

NO. I.—FROM GENEVA TO ZERMATT.

THE most direct route from London or Paris to Zermatt is by the Paris, Lyons, and Mediterranean railroad, *via* Dijon, Pontarlier, Vallorbes, and Lausanne. We, however, came through Geneva. Leaving Geneva, the Jura-Simplon Railway for about three hours skirts the lovely Lake Leman. After passing Coppet and Nyon, and dropping many passengers at each of these stations for the Divonne Baths, we had at Morgues a superb view of Mont Blanc, Coleridge's "Kingly spirit throned among the hills."

Lausanne came next, with its grand old cathedral, and its reminiscences of Gibbon and his (as one of Dickens's characters phrased it) "Decline and *Fall* Of the Roman Empire." At Lausanne we picked up a throng of tourists who had travelled thither direct from Paris *via* Dijon. Leaving Lausanne we rapidly passed Vevey, looking verdant, cool, and homelike; Montreux, sultry and nowadays "too much bricks and mortar;" the celebrated Castle of Chillon, recalling Byron and his chequered career; and here we left the lake-shore for the Rhone valley, and shortly entered the Canton of Valais by a defile, passing on to Martigny, where passengers bound for the Dranse Valley (Great St. Bernard) and Chamounix alight. Soon Sion looms in sight, with its curious cathedral and formerly fortified rock. We are now in a truly mountainous region, and, as in such places, legends and tales of the supernatural abound. Sion has its full share of them. The church bell is ringing, and one of our company tells the tale of Sion's saintly first bishop and his cock outwitting Satan.

We change carriages and dine at Viège (or as usually called, Visp) to take the narrow gauge Alot railway for twenty-two miles up the Viège Valley to Zermatt; five of these miles, at different intervals, are cog work. Zermatt has an altitude of 5,315 feet, and thus we ascend one of the loveliest railroad routes in all Switzerland. At the end of our journey we instal ourselves at a very comfortable resting-place at the Grand Hotel Mont-Cervin, one of the half-dozen good hotels of the well-known Seiler family. Zermatt is in gala attire, for its "season" is now in full swing. Its hotels and shops are brilliant with electric lights and its one long street crowded with visitors and tourists from many countries. Music, merriment, and cosmopolitan talkings resound everywhere; dancing on various verandahs. Although 5,300 feet above sea-level, on this bright July evening its atmosphere, pure and bracing, is most enjoyable; and in the clear starlight we behold, greatly uplifted above the village and valley, the unique peak of the majestic Matterhorn which seems "to pierce the heavens with its proud point."

Zermatt itself is 5,315 ft. above the level of the sea; the Matterhorn summit is 9,390 ft. above Zermatt. In Tauscher-Geduly's words, "It commands all the horizon; the neighbouring summits seeming to voluntarily efface themselves before it. All other hills around carry a *cuirasse* or a *casque* of ice; not so the Matterhorn. The

winds and the sun suffer no ice to gather on its superb shoulders and sides. After a snowstorm it appears as if only sprinkled with a powder of silver. Regarded attentively it seems not stationary, but to mount, mount ever higher into the ether."

It is not the highest of the summits in Valais, the Taschhorn, Weisshorn, Lyskam, Dom, Monte-Rosa excel it in height. Yet none other so vividly appeals to us.

The name of Seiler seems inseparably linked with that of Zermatt; for to the Seiler family Zermatt owes much of its present prosperity, and visitors to this Viège Valley most of their comforts. Before 1839 there was neither any accommodation nor any welcome whatever for strangers in Zermatt. Dr. Lauber opened a very small Inn here that year. In 1852 another was established, the *Hotel du Mont Cervin*. Two years later, the late Mr. Alexandre Seiler acquired the Lauber Inn, and changed its name to *Hotel du Mont Rose*. With the very efficient aid of his excellent wife, this Mont Rose House became popular, for both Mr. and Mrs. Seiler thoroughly knew "how to keep an hotel," a compliment, our American friends say, more to be valued than an election to their Presidential chair! The Seilers had, however, for a dozen years no easy task before them. Zermatt was almost utterly unknown, and its grand Matterhorn mountain considered inaccessible. The disaster to the Hudson-Wymer party in 1865 spread its fame far and near. The number of tourists began to increase, and they who came appreciated the constant courtesy and indefatigable attentions of the "Mont Rose" hosts. In 1867, Mr. Seiler acquired also the "Mont Cervin Hotel," and soon afterwards the "Riffelhaus," over 3,000 feet above Zermatt, the earliest inn at so high an altitude in this locality. In 1884, he built the handsome Riffelalp Hotel (7,307 feet altitude), which remains to-day deservedly the most popular house in the whole of this part of Switzerland. The Seiler reputation became world-wide, and many flocked to his hospitable houses from all lands.

Mr. Seiler died in July, 1891, and his wife four years later, rich in the esteem of all who knew them. The hotels he established on so firm foundations continue under the able management of his sons "prospering and to prosper." Zermatt has prospered and must prosper with them. In a lovely valley, environed by glorious hills and grand glaciers; endowed with an atmosphere invigorating and salubrious in the highest degree, as Professor Jung says:—"There is, in this little corner of the earth, that which excites the curiosity of the scientist and satisfies the aspirations of the artist, rouses the activity of the inert, and consoles the mind of the despondent. In this time of universal unrest thousands flock hither year by year; sufferers from ennui and pessimists lose here their moral lassitude; they, whose bodies are alone feeble, recover vigour in the vivifying air of these heights; all take away with them a store of new energy, a capacity to feel better, to understand better, in a word, *to live better*."

SCARLET fever in a somewhat bad form is prevalent at Cheltenham College. The annual cricket match between the College and Marlborough College which should have been played on the Marlborough ground on two days last week, did not take place

The Operating Theatres.

ROYAL FREE HOSPITAL.

OPERATION FOR UNUSUAL CONDITION OF THE GALL-BLADDER.—MR. BATTLE operated on a stout man, æt. about 54, a stable-helper, who was suffering from severe abdominal pain. The patient stated that he had been quite well until two evenings before, when he was taken with severe pain in the right side of the abdomen; this had continued since, so that he had been unable to leave his bed or even sleep. There had been no vomiting, and he had had no rigor. The pain had not been paroxysmal, but had remained of the same intensity, so that he was eager to have anything done. On examination he was a very stout man, with a dusky face and a tendency to bronchitis; he also had hard arteries with a little albuminuria. Examination of the abdomen showed it to be distended, and to contain a considerable amount of free fluid. Just below the right lower ribs, below the usual situation of the gall-bladder, was a hard, very tender swelling, which was dull on percussion; it was not the shape of the gall-bladder, being more irregular in outline, and not moving well with respiration. He had never had any difficulty with the bowels, which had acted freely after medicine the morning before. He remembered that three months before there had been pain in the same situation, but he had not been obliged to knock off work, and it had only lasted four or five days. An incision was made over the swelling through the upper part of the right rectus. The swelling proved to be matted omentum of considerable size, about the gall-bladder; the condition of the latter was very unusual. When the omentum had been separated, the gall-bladder was found under the liver (which was slightly enlarged); it was of a deep red colour with splashes of a whitish yellow on it, very tense and hard; it could be brought to the surface only by pushing the liver up under the ribs. A trocar and cannula pushed into the apex after the peritoneum had been protected with sponges and gauze, gave exit to a large quantity of thick bile, which shot from the tube, showing that it had been kept in at a considerable tension. The gall-bladder was pulled up and sutured to the wound; various small gall-stones escaped when an incision was made to enlarge the puncture. The lower part of the wound was sutured, whilst through the middle portion the ends of strips of gauze were brought, which completely shut off the gall-bladder from the peritoneum. A drainage tube was placed in the opening of the gall-bladder, but little appeared to come through it. A good deal of fluid escaped from the peritoneal cavity, but it was not purulent nor in any way offensive. Mr. Battle said it was difficult to account for the patient's symptoms as they did not correspond to the ordinary symptoms of obstruction of the cystic duct, and although the operation had relieved the man the exact cause of the condition of cholecystitis remained to be proved. There had been no evidence of calculus before operation, and those found at the time of the operation were too small to block a normal duct. It was considered that the blockage had not been relieved, but the main condition did not admit of further treatment. Excision of the gall-bladder would most likely have proved fatal.

WEDNESDAY, JULY 19, 1899.

THE TEMPERANCE QUESTION.

FOR some years there has been a general tone in the medical profession of neutrality upon the question of temperance. There is no doubt but that alcohol was pushed too far some years ago, when Dr. Todd's authority had weight. When a man broke his leg and was taken to a hospital the first thing to do was to give him some brandy. Such was fashion, even in the practice of medicine and surgery. Common observation brought about a reaction, and doubt began to influence the minds of many. We have now reached a condition in regard to the temperance question something like that which has occurred in politics. There are a few holding strong views on both sides, but the great majority is in *medio*. The evils of excess in some are not very clearly proved to be curable by total abstinence in others. Prayer and total abstinence may be regarded by some with great confidence as curative or preventive agents; but experience does not bear out the view that maladies are much benefited by such treatment, for alcoholism is a malady, and must be dealt with scientifically and not sentimentally. As with the opium question in the East, there is much to be said on both sides. When we recall Bishop McGee's declaration that he would rather see England free than sober, and compare this with the active crusade carried on by some of the best of our clergy to enforce total abstinence, the doubt arises naturally in the mind whether religion ought to have any influence whatever in dealing with the question, if regarded from a social or political standpoint.

The most important point which the medical profession ought to debate is the cause or causes to which alcoholic excess may be referred, whether in the individual or the people. There is a curious condition of religious emotion which creates prejudice against science; and to this it is we must refer the injury done by some ministers of all religious denominations to the advance of scientific knowledge and civilisation. It is not the fault of those who feel this fear; it is their misfortune, and may prove a trouble to others. If we consider the temperance question purely from a medical point of view, as we ought, and if we have the energy and character to educate those who cannot study it in the same way as the physician is entitled to do, we may assist the politician when the difficult question of Legislation is interesting the great jury of our country. If we were asked the apparently simple question, What is the value of alcohol as a medicine? we should not find it an easy one to answer. Alcohol may be a poison, but "poison heals in just proportion given;" and if we find a friend asserting that he would rather die than touch alcohol whatever its value may be if used properly, it is of no use trying to discuss the matter with him. If we look a little closely into the way in which alcohol is obtained we are compelled to draw the line very distinctly between that part of the process which is not the work of man, namely, fermentation, and that which is, namely, distillation. It looks as if Nature had provided us with the means to change certain substances from one condition to another by which change they are made more suitable for the human body. What does bread owe its great value to but fermentation? and to what extent are we acting wisely in extracting from the fermented juice of the grape or other liquid one of the products of the singular series of changes effected by the fermentation and which can possibly be used so variously for good or ill? If we are going to adopt the principle that nothing which Nature provides us with should be used for good if it can be possibly used for ill, where should we be? Virtues may merge into vices, and *vice versa*. We cannot but respect those who practise self-denial for the benefit of others, and though this virtue may not possibly become a vice, its value as an agent for good may be practically *nil*. If there is a virtue in eating unleavened bread for a few days in the year, some may think it would be a greater one to eat it always. It looks as if one of the lessons to be learnt when we compare the practical use of fermentation with the refusal of it, is the difference between knowledge and ignorance. We can understand the view

Of Man's first disobedience, and the fruit
Of that forbidden tree, whose mortal taste
Brought death into the world . . .

though we could not agree with it. The time has come when this temperance question fairly falls within the territory of sanitary science, and if the profession will treat it in the spirit it demands the public will be glad, and good will follow.

THE METROPOLITAN ASYLUMS BOARD.

It is always a matter of some difficulty to realise the progress of contemporary history. In recent years, however, the task has been lightened to a considerable extent by the modern practice of issuing systematic reports of official work. Among such records those of the Metropolitan Asylums Board are worthy of careful attention, marking, as they do, one of the chief avenues of advance of the great modern art of preventive medicine. The annual report of the Asylums Board for the year 1898, which has just been published, contains a mass of information of first importance. Instead of being issued in the form of a chairman's report, it has this year been entrusted by Sir Edwin Galsworthy to the Statistical Committee, who have accordingly issued a report of the Board in two volumes. The total expenditure was £719,128, or an excess of about £53,000 on the previous twelve months. The increase is strictly in keeping with the tradition of the Board, which has steadily and without a single exception increased every annual outgoing since its comparatively modest start at £66,469 in 1867. At the same time, it is only fair to remember that during the period mentioned the population has greatly increased, and the available accommodation has gone up by leaps and bounds. But in spite of a higher rateable value subject to taxation, the rate for 1898 was higher than any yet made. The Asylums Board, however, have never professed to cultivate the humble virtue of thrift, and money has always been bestowed on them by the ratepayer with unstinting hand. The chief complaint has been that in spite of lavish expenditure the necessary accommodation has not been forthcoming for the housing of the infectious sick of London. In the year under report we are happy to find official evidence that the reproach of inadequate equipment has been removed. This satisfactory result appears to be attributable mainly to two causes—first, a decrease in infectious diseases; and, secondly, an increase in hospital accommodation. With regard to the former point, the committee report that the number of cases of infectious disease notified under the Public Health (London) Act, 1891, during 1898 amounted to 37,316 and showed the substantial reduction of 8,101 as against the previous year. Bearing upon the second point is the fact that the percentage of the total number of legally admissible cases actually admitted has touched 65·5 per cent., as against 58·5 in 1897, and 33·6 in 1890, the first complete year in which compulsory notification was in force. Although it is, of course, impossible to found any trustworthy conclusion upon the figures of a single year, it is nevertheless impossible to avoid altogether the hope that the days of general decline in infectious diseases may be at hand. Preventive medicine by the aid of vaccination, isolation, and general sanitation has reduced small-pox to vanishing point. Why should not an equally happy result be attained in the rest of the specific diseases as our knowledge of cause and effect is carried ever deeper and deeper?

The following figures are most encouraging: The admissions from scarlet fever fell from 15,113 in 1897 to 12,125 in 1898; "fever" from 1,481 to 1,417; and small-pox from 70 to 5. It is to be hoped that some day the reduction of those diseases will be so great as to furnish the Board with spare accommodation enough to enable them to attack the terribly fatal maladies, whooping-cough and diarrhoea. To a sanitarian nothing is impossible, especially if unlimited funds are forthcoming. Little is mentioned in the report about the troubles that have arisen with regard to the Brook Hospital. In the space at command it is impossible to do more than glance in a brief and general way at the leading features of this excellent report, which will be found to repay perusal by those interested in Public Health administration. The mass of carefully-arranged statistics and the clearness of statement more than justify the relegation of the task of reporting to a committee. It is too much the tendency of a one man report to run on the lines of the special pleader, a principle that is hardly favourable to healthy growth in public departments. We purpose dealing in a further article with the extremely important question of the housing of Poor-law children under Mr. Chaplin's Order. Meanwhile the Metropolitan Asylum Board may be congratulated on the addition of one more year to their records of solid achievement.

THE GOVERNMENT AND THE DEATH-RATE FROM CANCER.

THE Government have refused the request of the Cancer Society to appoint a Royal Commission to inquire into the causes of the increase of cancer. They allege that the attention of the Local Government Board has been called to the large increase in the number of deaths from the disease, and that as opportunities had arisen, they had caused scientific inquiry to be made into the natural history and causes of cancer. Moreover, they assert that the President of the Local Government Board has been advised that in the present state of our knowledge on the subject, no useful purpose would be served by the appointment of a Royal Commission. In view of the booming which is taking place, both officially and individually, of tuberculosis, the refusal of the Government to have anything to do with cancer is, perhaps, natural enough. The tubercle bacillus has become quite an aristocratic microbe ever since it was discussed in the royal presence at Marlborough House, and the aristocracy as well as the Lords, spiritual and temporal, are now vying with each other in their efforts to show the interest that they take in everything belonging to it. All this, of course, cannot be without benefit to the public, and upon these grounds we have nothing to complain of, but it is obvious that until the public interest begins to wane in tuberculosis there cannot be much chance of a hearing for cancer. Nevertheless, as we have repeatedly pointed out in these columns of these two

fatal maladies cancer is the one in the investigation of the etiology and natural history of which the State should take some active part. It is not a sound argument to advance that the subject of cancer belongs at the present too much to the domain of science to make a Royal Commission upon the subject either necessary or expedient. In assuming this position a morning contemporary altogether misjudges the condition of affairs. The writer of the article adds truly that the disease has for years been the subject of incessant study and that something has been done to elucidate its nature. But he then proceeds to discuss the various hypotheses and opinions which have been expressed regarding its origin and frequency, and in the end makes out as strong a case as possible for a State Inquiry, despite the fact that he opposes State interference in the matter. Clearly a Royal Commission on Cancer could not fail to be productive of good. In the first place it would be able to collect and sift the evidence bearing upon the increase of the disease; next, it might deal with the disputed points relating to its geographical distribution in England; again, much valuable information might be obtained, through its means, regarding the so-called "cancer-houses." All these are matters respecting which differences of opinion exist, and concerning which there is, of course, a great deal that can still be said. Under the circumstances, therefore, it is absurd to state that the study of cancer entirely belongs to the domain of science; a State inquiry into its natural history, as apart from its pathology, we again repeat, is urgently called for. The scientific side of the disease may be safely left to the pathologists and bacteriologists, but, we maintain, that it is the duty of the Government to ascertain the true facts regarding its increase, climatology, and prevalence in England. Quite possibly, however, the subject of cancer is never likely to command the same public attention as that which belongs to tuberculosis, mainly, perhaps, for the reason that it deals with a disease the mere reference to which carries with it to many persons the recollection of fateful scenes of human suffering. Nevertheless, painful, and in some respects repulsive, as a national inquiry into a terrible disease like cancer might be, it should not be shirked upon grounds of sentiment. Sentiment should not be allowed to weigh in the balance against expediency in such a case. The Cancer Society is still in its infancy, and we feel certain that it has a great future before it, and its initial step in bringing under the notice of the House of Commons the necessity of having a Royal Commission appointed to inquire into the disease was admirable in every way. Although its advances were met with a rebuff from the Government, no great importance need be attached to this. We believe that this is the first occasion on which such a suggestion has been made in the House; it was, therefore, hardly to be expected that a favourable reply would have been

given. Meanwhile, by "pegging away" the Cancer Society may find in a few years that the public will join them in insisting upon a State inquiry into cancer, the necessity of which was urged last week.

Notes on Current Topics.

Photographed in Grave Clothes.

A CURIOUS professional incident is reported from New York with all the gravity and detail that betoken fact, but all the same one is accustomed to accept stories of this stamp from the New World with some amount of reserve. The tale is that Dr. Mary Walker, a well-known citizen, was desirous of finding out what her appearance would be when dead. She accordingly had herself photographed when laid out as she would be for the grave. This strange picture is now being published broadcast over New York, so says the *Morning Leader*. The information is added that flowers are strewn over the dress in which she lies, and on the lapel of her jacket is a bronze medal, which Dr. Walker says was presented to her by Congress shortly after the Civil War. Of course, as everyone knows, on this side of the Atlantic any attempts to attain publicity by methods that savour of self-advertisement are rigorously condemned by an unwritten code of laws. In America, however, there are no such restrictions, and we must confess to a certain sense of admiration for the daring originality of the idea, supposing it to have been actually carried out with all the pomp of gruesome circumstance described by the newspaper correspondent. One is reminded of the ancient saw that whatever is worth doing at all is worth doing well. To be photographed as a corpse is "going one better" than eccentrics of the Sarah Bernhardt type, who travel about with and occasionally sleep in a coffin.

The Rating of Hospitals.

THE London County Council have decided, by a small majority, not to recommend, for the present at any rate, the exemption of hospitals from rates. Sir Arthur Arnold and Dr. Collins urged the Council to express a favourable opinion, but their eloquence was without avail. In the course of the discussion it transpired that churches and chapels, voluntary schools, literary and scientific societies, Sunday and ragged schools, and Volunteer buildings are all exempted under various Acts of Parliament. In the face of those facts it seems an extraordinary and unaccountable thing that the medical charities, which are not less directly essential to the welfare of the mass of the community than many of the institutions mentioned, should be grievously mulcted of the funds subscribed to them by charitable donors. The amount of taxation levied from the hospitals yearly is no less than £21,000. Here is the opportunity for the Prince of Wales's Fund to step in and render a solid service to the Metropolitan hospitals. Let them bring the whole weight of their immense social influence to bear upon Parliament to redress this

grievance, for it is nothing less. The total debt of the London medical charities reduced by £21,000, for that would be the practical outcome of a special exemption Act, would lessen the enormous burden that the Prince's Fund has undertaken. The chief objection raised in the County Council was that they should do nothing towards exempting hospitals until they had something to do with the management of them. How does that principle apply to churches, chapels, learned societies, Sunday-schools, and Volunteer buildings?

Fined for Non-Notification.

A MEDICAL man in practice at Kington, Herefordshire, has recently been fined for failing to notify the District Medical Officer of Health of a case of infectious disease within the meaning of the Notification Act, 1889. From the evidence it appeared that a child was attacked with what defendant himself openly admitted to be scarlet fever, both to the Inspector of Nuisances and to the Medical Officer of Health. Notwithstanding that fact, the case was never formally notified. A serious feature of the affair was that a girl in the employ of the infected household was allowed to enter the patient's bedroom. She went home and communicated the disease to five persons, among them being her mother, who had been recently confined. The prosecution seems to have been conducted in a most candid and temperate way, and the only defence offered was that there had been no attempt at concealment on the part of the defendant. The Medical Officer testified that the latter said in the course of conversation that he preferred "to wait for the peeling before he notified." Such a course must be not only absolutely unnecessary, but full of danger in the vast majority of cases. Here and there a doubtful attack may come under observation, but even then it would be wiser to run the risk of sending in a mistaken diagnosis, rather than spread a dangerous disease broadcast by delay and inexcusable timidity. The defendant in this instance was fined £1 and costs, and by his unwisdom has placed himself in a most unenviable position. It seems almost incredible that any medical man should allow himself to incur such an amount of vexation and notoriety by neglect of a simple legal formality.

A Threatened Water Famine.

THERE seems to be some foundation for an ugly rumour that has lately been in circulation as to the possibility of a general water famine in the metropolis. May and June were very dry months, during which a far smaller amount than the average flowed over Teddington Weir. While Londoners draw their water from the Thames they will always have to run the risk of a scarcity of water in time of drought. The peculiar danger of the present position, however, arises from the fact of the connections that have been made between the mains of the various companies. Supposing that the East London Water Company glide into their usual summer failure then the Thames-fed Corporations, called upon as they

would be to make up for the shortcomings of the Lea, would be likely to find themselves in serious distress. While one has no wish to meet trouble half-way, yet, on the other hand, it were indeed foolish not to look ahead in a matter so important as the water supply of a vast community. Should any such complication as a general water famine arise, Londoners, as a whole, will perhaps be induced to consider things seriously, for a failure affecting north, south, east, and west alike would not be taken so complacently as one that threw its brunt on the great labouring quarter of the Metropolis. The Government can hardly be congratulated so far on the handling of the London water question, and a failure of supply this summer would cause a good deal of heart searching, both inside and outside the Houses of Parliament.

The Relations of Public Vaccinators to Private Practitioners under the Vaccination Act.

THE following sensible suggestions are offered by the Bradford and West-Riding Medical Union for the guidance of public vaccinators in their dealing with the patients of other practitioners. If honourably adhered to it is claimed they will not interfere with the official duties of the public vaccinator, and will protect the interests of private families and family practitioners. 1. The public vaccinator before entering a house should ascertain whether there is in fact, as reported to him, an unvaccinated child in the house. 2. In the event of his being informed that there is not an unvaccinated child in the house: or if there is, that arrangements have been made for its private vaccination, the public vaccinator should then at once retire. 3. Should the public vaccinator be informed that the child is too ill to be vaccinated, he should retire without entering the house. It is not his duty to require a certificate of unfitness to be supplied, that is the duty of the vaccination officer. 4. It is not the duty of the public vaccinator, nor is it compatible with the dignity of his profession to endeavour to persuade the parents to let him perform the vaccination for which he is to receive a specified fee from the public funds. 5. The public vaccinator as such should not proceed to examine any child as to its state of health, unless he has been requested to vaccinate it, and unless he is *bona fide* under the impression that the child is fit to be vaccinated. In any other case his duty is to abstain from all interference with the child. 6. Any reference as to the superiority of his methods or his vaccine, made with the view of being allowed to vaccinate, would be most unworthy, and could only be exceeded in this respect by any attempt to decry the methods or the vaccine employed by other practitioners. 7. If he is required to vaccinate a child belonging to a family who are the patients of another practitioner, he is in honour and in self-respect bound to avoid any act or word which might tend to prejudice the professional interests of the family medical attendant, or which could be regarded as an attempt to induce the

family to employ him as their family doctor. 8. The public vaccinator is not authorised to call, for the purpose of vaccinating a child, until after the expiration of the twenty-four hours' notice which he is required to give.

Medical Cromwellianism in America.

A MEDICAL paper issued in Philadelphia has published a most satisfactory account of the moral character of the recent annual meeting of the members of the American Medical Association at Columbus. Indeed, every one in the profession in the United States must feel delighted that the editor of the journal in question has found himself in the position of being able to give such a good report of the conduct of the members. He says that "even in such a matter as personal ethics and dignity there was at Columbus a most noteworthy absence of what has previously been an altogether too conspicuous presence of the guzzlers and all-nighters. There were even strange stories of 'Nothing stronger than lemonade, please,' this year, and the banquets, even of the so-called American medical editors, were free from stories in which the delight in witless filth has often been an astonishing element of attractiveness. There is plainly to be an end of the 'dry smoker' and the 'roysterer.'" The members of the British Medical Association who intend visiting Portsmouth for the annual meeting should take these remarks to heart, and make a point while there of drinking nothing stronger than water, going to bed punctually at ten o'clock at night, limiting their conversation, except at the sections, to philanthropic schemes relating to the parochial clergy, and of observing an entire abstinence from tobacco-smoking—otherwise they might expose themselves to the accusation of being roysterers and "all-nighters." Has the spirit of Cromwell been acting upon the feelings of the members of the American Medical Association, or are the remarks above quoted merely imaginative sallies of the editor of the journal in which they appeared?

The Liverpool School of Tropical Diseases.

MR. CHAMBERLAIN is evincing quite a paternal interest in the progress of the Liverpool School of Tropical Diseases. In commending the enterprise of the authorities to send a research expedition to West Africa, he has written to say that he has learnt with satisfaction that the expedition of the Liverpool School is being sent, and that he appreciates the energy and public spirit shown by the committee of the school in the matter. He also adds that the authorities at Sierra Leone will be instructed to give every facility to the work of the expedition. After the expedition has completed its work at Sierra Leone it will proceed to Accra, where further investigations will be carried out. The Belgian Government, attracted by the excellent organisation now existing at the Liverpool School of Tropical Diseases, have despatched an officially appointed delegate to visit the Institution and report to the Government. Altogether, it would seem that

the Liverpool School will ultimately take the lead in providing for the study of tropical diseases in this country.

The London Hospitals and the Anti-Vivisectionists.

THE Honourable Sydney Holland is well known to be one of the most zealous and successful managers of hospital charities in London, and his reputation in this regard has been gained by a devotion to service on their behalf which has won for him unstinted praise from all who are interested in the same work. One of the hospitals upon the success of which he has expended much energy, and which in consequence now occupies quite a unique position among the smaller institutions of the kind, is the Poplar Hospital for Accidents. Owing to Mr. Holland's advocacy of its claims this hospital enjoys a large measure of public support, but in a fair and open manner Mr. Holland has shown that the charity is worthy of the support which it has received. Despite this, however, we feel it our duty to draw Mr. Holland's attention to a circular letter which has been issued by the Honourable Stephen Coleridge in which the latter seeks unfairly to disparage another hospital for the purpose of alienating subscriptions in favour of the Poplar Hospital for Accidents. The facts are as follows: Mr. Bird, the chairman of the West London Hospital, wrote a letter to the *Times* stating that the Pathological Laboratory which had recently been organised by the Staff of the Hospital in connection with the West London Post-Graduate College, had not been licensed for the performance of experiments upon animals. Whereupon the Honourable Stephen Coleridge drafted a letter, a copy of which was sent to every subscriber to the West London Hospital, in which he stated that two members of the Staff were licensed under the Vivisection Act, by which they were enabled to dispense with the obligation to kill the animals by anaesthesia after the experiments had been performed. The inference which the Honourable Stephen Coleridge evidently intended should be drawn from his statement was that the two members of the Staff in question made use of the West London Hospital laboratory for the prosecution of their researches. Whereas, of course, nothing of the kind is the case. Despite, however, the obvious unfairness—to use no stronger word—of this attack upon a well-known and excellent charity, the Honourable Stephen Coleridge used it as a plea to urge the subscribers to the hospital to transfer their subscriptions from the West London Hospital to the Poplar Hospital for Accidents, where, as he states, an undertaking exists not to appoint or retain licensed vivisectionists on the staff. It is difficult to believe, despite the interest which he takes in the Poplar Hospital for Accidents, that the Honourable Sydney Holland would desire to see his institution made the means of impoverishing another hospital for the reasons advanced by the Honourable Stephen Coleridge. Indeed, we feel sure that Mr. Holland would be the first to repudiate such a method of raising funds for his hospital. However, the matter is one which so

largely affects the interests of the medical charities in London that we trust public steps will be taken to discount the efforts and statements of the Honourable Stephen Coleridge upon each occasion that he attempts—unwarrantably—in this way to interfere with their concerns.

The Fellows' Meetings at the Royal College of Surgeons, England.

AFTER the annual election of members of Council at the Royal College of Surgeons, on the 6th inst., the president and two vice-presidents of the Council attended in the theatre of the College in order to hold the annual meeting of the Fellows. But for the third time in succession, at the Fellows' meetings, the necessary quorum was not obtained, and consequently no business could take place. The president, Sir William MacCormac, in alluding to this fact, expressed his regret that not more than twenty-one Fellows had attended, inasmuch as the Council had hoped that a discussion would have taken place at the meeting upon the question of the proposed supplementary charter. But there is no disguising the fact that at the present time College politics are dead, so far as the Fellows are concerned, and if the Council were to decide to abolish the Fellows' meetings entirely there would probably be no one who would complain of their action. That this state of affairs now exists does not prove a prevalent apathy among the Fellows concerning the affairs of their College; it merely is an indication that the old body of reformers have ceased to be active, and that the Fellows generally have for the time being come to the conclusion that the present government of the College does not call for their interference. It would now seem to be the case that if the Council are desirous of obtaining the opinion of the Fellows upon the question of the proposed new charter, the expedient will have to be resorted to of calling a special meeting of the Fellows for this express purpose. However, in view of the fact that there cannot be two opinions as to the desirability of applying for the new charter, there does not appear to be any sufficient reason why the Council should approach the Fellows upon the subject.

German Practitioners in England.

WE are informed that Dr. Pagenstecker, the ophthalmic surgeon of Wiesbaden, has taken time by the forelock and made a bid for practice in London. He has established in Wimpole Street a German assistant who will represent him and see confiding British patients on his behalf. The state of the law is such that without an English medical diploma any German can establish himself in medical practice in England, and provided that he was not called upon to sign a death certificate no one could interfere with him. There is but little danger of a practitioner who confines himself to ophthalmic surgery being required to sign a certificate of death, and thus the assistant of the Wiesbaden surgeon may be regarded as secure from interference by the law. Verily, the "law is a hass" in this instance, and nothing could

more plainly show how ill-protected English practitioners are in their own country against the invasion of competing aliens.

Another Case of Total Extirpation of the Stomach.

On the 9th ult., Dr. Kocher, of Berne, Switzerland, removed the whole of the stomach of a woman, æt. 40, for carcinoma of the pylorus. The duodenum and œsophagus were united, and the abdominal wound was sutured, a small glass drainage-tube having been inserted. The patient lived three days and a half and then suddenly died. At the post-mortem examination some peritonitis was found as the result of necrosis of a small portion of the wall of the transverse colon.

Union Analysts for Ireland.

THE recent order of the Irish Local Government Board, which defines the qualification of the Analyst to a Board of Guardians has created a good deal of effervescence among pharmacutists. It was quite necessary that such an official definition should be provided, inasmuch as a number of Boards of Guardians had already availed themselves of the new appointment to "job" in their own friend the local chemist, but it appears to us that the definition is unsatisfactory. It, for instance, makes Fellowship of the Institute of Chemistry a qualification *sine qua non*, and, in other ways, it indicates the appointment of a pure chemist, not of a pharmaceutical expert. In our opinion the Public Analyst should embody both specialities. His chemical knowledge will be indispensable for analysis outside the region of drugs, but, within this area, it will be insufficient for the desired object. The purity of pill masses, compound liniments, and such-like therapeutic mixtures can be ascertained by laborious and prolonged analysis, but, be it said with respect, the purchasing public would, for this purpose, have more confidence in the educated nose, tongue, and eye of the experienced drug buyer than in any analyst, however eminent. We suggest that the Local Government Board should try to make a definition which would combine the scientific and the pharmaceutic qualifications, and should revise its rule accordingly.

The Liverpool Skin Hospital.

THE Liverpool medicine profession can hardly be congratulated on the latest phase of the "scandal" at the Hospital and Skin Diseases in that town. After the two members of the staff had been hurriedly dismissed by faggot voting, the vacant posts were forthwith advertised. It has since been publicly stated that about thirteen doctors have applied for the vacancies, in addition to three others who have been nominated by "a professional man of high standing." Supposing the latter statement to be true, most of our readers will agree that the height of the status of the gentleman in question is likely to undergo a reduction to vanishing point. As matters stand, two members of the staff have been dismissed for bringing charges of a grave nature

against their senior, who has taken no steps to establish his *bona fides* by bringing an action for libel. How any committee of honourable men can be induced to make themselves responsible for such a proceeding must puzzle the average human intelligence sorely. However, similar mysteries are not unknown in the hospital world. It is not so many years since that a notorious skin hospital in the metropolis defied public opinion in much the same way. Three of its medical staff resigned because of the failure to clear the management of various charges. Their places were at once filled up by other medical men, some of whom hold to the present day the posts obtained in a manner that the keenest competition could not justify. There seems no prospect of things being settled yet awhile at the Liverpool Hospital.

The Case of Dr. Lamont.

GREAT satisfaction is expressed in Scotland by members of the profession and others as to the generous and kindly speech of the leader of the House of Commons in reply to the statements made by a number of Scottish representatives, descriptive of his unjust and malicious treatment. The Lord Advocate, of course, had to do his best to whitewash the officials of his department, a work of no little difficulty even in his hands; but it was only when Mr. Balfour intervened that Dr. Lamont received complete exoneration, and notice was given that he would be compensated for out-of-pocket expenses. The most important result of the discussion on this case lies in the public exposure of the wrongs which may be done, and frequently are done, by local authorities to their medical officers, without these officials having any power of appeal or of obtaining redress through the Local Government Board for Scotland. The virtuous indignation of members of the Opposition at this state of affairs contrasts peculiarly with their former attitude, which, if we mistake not, was the converse.

Instruction in Pharmacy.

THE Senate of the Royal University of Ireland has intimated to the Pharmaceutical Society that it will, in future, recognise instruction only in a regular medical or pharmaceutic school, not in a chemist's establishment. We are aware that the existence of pharmacy departments in medical schools is owing to the fact that when the certificates of chemists and hospital dispensers were accepted, those documents could be bought for a sovereign across the counter as readily as a seidlitz powder. Therefore the Colleges thought it necessary to ensure *bona fides* by establishing their own pharmacy schools. Without suggesting that the school courses in this subject are not as genuine as the assiduity of the teacher can make them, we have no confidence whatever in them as proofs of pharmaceutic education. We do not believe in the possibility of communicating a sufficiency of such knowledge in a few prelections in a lecture theatre, and we would sug-

gest that the Licensing Bodies should surmount the difficulty by abolishing the pharmacy certificate altogether, and leaving the candidate to "get up" the subject for examination any way he can.

"Closed for Repairs."

THE spectacle of so many of the large hospitals, special and general, evacuated of their suffering contents for the purpose of "alterations and repairs," excites a feeling of curiosity as to the fate of those who would otherwise be enjoying (?) their hospitality. Although some sort of arrangement is usually attempted in respect of the more serious cases there can be little doubt that much hardship is inflicted on the suffering poor by the lack of concerted measures between the various hospital authorities. It is one of the drawbacks of the "voluntary" system of hospital maintenance that the managers of these institutions escape any sort of official control, otherwise no hospital would be permitted to close all its wards at once, just in order to give the staff a holiday. Apart from the hardship to patients, the present system causes much heart-burning among the junior members of the medical staff, who, the surgeons especially, look forward to their seniors' holidays to enjoy positions of responsibility and experience which they are yearning to fill. The senior man, on the other hand, appears indisposed to gratify his junior's aspirations, and gladly falls in with the proposal to shut up the hospital as a whole. The occasions when such a course can be justified by the magnitude of the alterations contemplated must be rare indeed, and obviously it must be as easy to whitewash and disinfect wards *seriatim* as altogether. This is a matter to which subscribers to hospitals would do well to direct their attention, for only a little judicious inquiry is required to bring about a desirable reform.

A Reverend Quack.

A SINGULAR career was unfolded, in part, on Saturday last, at one of the Metropolitan Police Courts, where one, Maguth, was brought up on a coroner's warrant charging him with manslaughter. It appears from the evidence that the accused started adult life in holy orders, but left the church in 1879 to take up with "medical botany," on the strength whereof he described himself on a brass plate as "Dr. Maguth, LL.D., Scientific Medical Botanist and Hygienic and Dietetic Adviser in all Ailments. Advice Gratis." In the exercise of his unauthorised functions Maguth attended a child, æt. 7, who was suffering from "ulcerated throat," which, however, he failed to identify as due to diphtheria, and the child died. Obviously there is hardly a disease in which a prompt and correct diagnosis is of greater importance than diphtheria, for on its recognition and early treatment the ultimate result must, in most instances depend. Moreover, an unrecognised case of diphtheria is a standing form of infection, the more potent for evil by reason of its nature not being suspected. We trust due prominence will be given to these points when the

case comes up for trial. The accused has been liberated on bail pending further inquiry.

Infectious Diseases in London.

It is disquieting thus early in the season to be confronted with a notable increase in the number of infectious cases in the hospitals of the Metropolitan Asylums Board. It is, moreover, very disappointing to find that all the money spent in notification or isolation seems to be without effect in restricting the spread, for instance, of scarlet fever, and in attenuating its effects. The seasonal rise and fall recur with tedious monotony, and the numbers, as compared with those of previous years, invariably show a steady increase, an increase which renders necessary the building of another palatial edifice every year or two for the accommodation of the sick. This result may, to a not inconsiderable extent, be attributable to the fact that the public are getting accustomed to the idea of transference to hospital and offer less opposition when removal is suggested. The laxity of the Board in enforcing payment from those in a position to pay may possibly explain this change of front, and one of these days the Board's policy in this respect will have to be taken into consideration.

A Midwife's View of Infantile Bronchitis.

Now that the subject, midwives' registration, is so much before the public, it is with more than ordinary interest one turns to cases that illustrate their potential medical capabilities. From this point of view the evidence of a midwife given last week at Stroud is not without its instructive and suggestive aspects. The occasion was a coroner's inquiry into the death of an illegitimate infant of a farmer's housekeeper in the district. The midwife deposed that she attended the mother who was confined of twins. One was born at four o'clock in the morning, the other twenty minutes later. Witness did not expect either of them to live, but everything was done for their comfort. The second child was very weakly, and could hardly breathe. It appeared to be suffering from bronchitis, and died about nine or ten hours later. She thought the child died from bronchitis and weakness, and that no blame was to be attached to anybody. She left no one in the room, but the farmer's daughter was downstairs. The attention of those who are agitating for the registration of midwives should be drawn to this incident. The gross ignorance that attributes weak breathing in a newly-born infant to bronchitis is just what may be looked for from women untrained in medical matters. If that sort of view were accepted a vast number of infants would die simply for want of a little artificial respiration. What had the coroner to say to the fact of the mother being left alone with these ailing twins within a few hours of their birth?

DR. PARRY, of Pont-y-Cymmer, Wales, has recovered £5 damages and costs against a local newspaper, a writer in which had charged him with neglecting his patients for yachting. It subsequently

transpired that the newspaper had been "hoaxed," and could not trace their anonymous correspondent.

MR. KEARLEY'S Food Products Bill, the Midwives Bill, Mr. Boulnois's Conscientious Objectors Bill, and Mr. Begg's Companies' Act Amendment Bill have all been dropped within the past week.

THE occurrence of Carytes in various districts in Ireland has been brought to the notice of the County Councils by the Irish Industrial League with the view of having it ascertained whether the deposits will pay to work.

THE present century has not produced, and is not likely to succeed in giving to the world a second Lawson Tait. Nevertheless, at the annual meeting of the Liverpool Samaritan Hospital for Women, held last Wednesday, "Dr. Lawson Tait was elected Consulting Surgeon to the hospital." Would that our late distinguished *confrère* were in the flesh to accept the honour. The hospital committee evidently does not keep itself posted in the everyday affairs of this mundane existence.

Medico-Legal Notes.

By W. J. JOHNSTONE, B.L.,
Dublin.

THE ROYAL COLLEGE OF SURGEONS, ENGLAND, AND THE INLAND REVENUE DEPARTMENT.

THE English Court of Appeal has been considering in an important case the position and history of the Royal College of Surgeons of England. The immediate object of the case was to get a decision of the Court as to whether the property of the Royal College of Surgeons, England, was subject to duty within Section 11 of the Customs and Inland Revenue Act, 1885, but incidentally some interesting legal light was thrown on the objects and history of the College. The facts were very simple. The section above referred to imposes duty upon the annual value of all property belonging to any body, corporate or incorporate; but there is an exemption from duty in the case of "property which, or the income or profits whereof, shall be legally appropriated and applied. . . . for the promotion of education, science, or the fine arts." It appeared that the annual value of the real property vested in the College during the year ending June 24th, 1894, was £7,200. The total value of the vested personal estate of the College on the same date was £187,195 17s. 11d., the income from which amounted to £5,833 5s. 7d. The College was assessed by the Commissioners at £3,161, and required to pay as duty the sum of £158 1s. The Commissioners allowed exemption in respect of the museum, and that part of the property which consisted of laboratories; but no exemption was allowed in respect of the library, the conservator's residence, the general offices, and the hall used for examinations. Sir Edward Clarke argued that the whole of the property of the College was "legally appropriated and applied" for the promotion of science, and was, therefore, not liable to duty. An alternative claim was put forward that, at any rate, the library of the College in Lincoln's-Inn-Fields, and the official residence of the conservator of the museum came undoubtedly within the exception in Section 2. The Court of Appeal, however, decided that no part of the property in question was legally "appropriated" for the promotion of science, and that the duty must be paid.

THE PURPOSES OF THE ROYAL COLLEGE OF SURGEONS, ENGLAND.—The judgment of Lord Justice Romer in the case is a valuable document from a historical point of view. He began by referring to the Act of 18 George III. c. 15,

which made the surgeons and the barbers of London two separate and distinct corporations, and he traced the history of the College of Surgeons from its incorporation by a charter of George III. in 1800 to the present time. From an examination of the various Acts of Parliament and the bye-laws of the College, he came to the conclusion that the objects and purposes of the College have a dual nature; firstly, the promotion of the science of surgery, and, secondly, the promotion and encouragement of the practice of surgery and the promotion of the interests of surgeons. No part of the College property was "legally appropriated" for the objects and purpose of the science of surgery. That is, there was no legal obligation on the part of the administrators of the College to apply their property for the first purpose and object as distinguished from the second; and, as a consequence, it was held that none of the property in question came within the exemption of Section 2. In the judgment it was assumed, of course, that property applied for the purpose, of the practice of surgery, as distinguished from the science of surgery, did not come within the exempting clause.

THE LAWS AS TO BAKERS AND BAKEHOUSES.

The decision of the Queen's Bench Division in *Schwerzerhof v. Wilkins* (19 Cox C. C. 22) is an interesting illustration of the construction of Acts of Parliament and the administration of statute law. It was considered necessary for public health and safety to pass the Factory and Workshop Act in 1895, Section 27 of which contains certain provisions as to bakehouses and bakers. Sub-s. provides that a place underground shall not be used as a bakehouse unless it was so used at the date of the passing of the Act—namely, January 1st, 1896. Certain underground premises were occupied by *Schwerzerhof* as a bakehouse. A complaint was preferred against him on behalf of the sanitary authority of the district, when the following facts were proved. The premises in question were fitted up as a bakehouse in 1879, and were occupied by a baker down to December, 1894. The tenancy ended then, and the landlord had the premises put into repair. In February, 1896, they were let to *Schwerzerhof*, who began to use them again as a bakehouse, and was so using them when he was summoned. On the facts the magistrates convicted, and fined the appellant. The Queen's Bench Division, however, thought otherwise. That court was of the opinion that one tenant going out and another going in did not stop the premises being used as a bakehouse, even though the premises happened, as in this case, to be untenanted on the crucial date, January 1st, 1896: that the place was being used as a bakehouse at the passing of the Act, and that *Schwerzerhof* ought not to have been fined. It never was the intention of the legislature that the vested rights of any owner of a factory or manufactory should be injured by the passing of the Act of 1895, and it seems that the above decision is clearly in accordance with that intention.

THE ABUSE OF HOSPITALS.

A SPECIAL General Meeting of the Bradford and District Medico-Ethical Society was called some months ago for the purpose of considering the question of Hospital Abuse. Several meetings were subsequently held, and the Committee now report that the following resolutions were passed, and seem of so much value as bearing on this important question, that we reproduce them in full:—

1. MEDICAL RELIEF IS CHARITY.—"That in the opinion of this Society, it is of the first importance that the Boards of Management of Public Hospitals, and the public generally, should recognise the principle that medical relief is charitable relief, and that the hospital funds are provided in trust for the benefit only of the sick who are unable to pay, when suffering from serious ailments, and that it is not only dishonourable but dishonest for other persons to take any part of these funds."

2. WAGES SCALE.—"That the Bradford and District Medico-Ethical Society approve the following Wages Scale for use in our hospitals:—For one person, when

in work, 18s. per week; for two persons, when in work, 23s. per week; for three persons, when in work, 28s.; for four persons, when in work, 31s. per week, with 3s. for each additional member of family. That cases of long-continued illness or cases for serious operation should be considered exceptional and should be recommended by their medical man."

3. INQUIRY OFFICER.—"That the necessary inquiries as to the inability of applicants for medical charity to pay for treatment at home cannot be satisfactorily made except by a special inquiry officer, and that all cases should be inquired into by such an officer."

4. SERIOUS CASES.—"That no patient who is excluded by the wages scale ought to be entitled to receive medical charity unless suffering from an ailment of so serious a nature that it cannot be properly treated except in hospital."

5. NO SMALL PAYMENTS TO BE TAKEN.—"That the acceptance of small payments from patients in receipt of medical charity, whether as a contribution towards the cost of maintenance or in return for medical treatment, is highly undesirable. This is not intended to interfere with voluntary contributions by grateful patients after the treatment in hospital has been finished."

6. RECOMMENDATIONS.—"That the system of giving recommendations to subscribers is objectionable, is greatly abused, and should be abolished."

7. CASUALTY PATIENTS.—"That casualty patients should receive first-aid and then if above the wages limit be referred to private medical men."

8. DENTAL EXTRACTIONS.—"That cases of simple extraction of teeth should be inadmissible."

9. OUT-PATIENTS.—"That out-patients shall be admitted to the hospitals without charge, subject to inquiry as to their monetary suitability. That patients sent by their medical men for a second opinion, but not for hospital treatment, shall be eligible without inquiry by the inquiry officer."

10. IN-PATIENT DEPARTMENT.—"That in-patients shall be admitted according to the wages scale, exceptions being made when operations are required, or when other extraordinary circumstances obtain. That no paying patients shall be admitted as such."

11. HOME-PATIENTS.—"That the home-patient department, as carried out in connection with the Bradford Royal Infirmary, is much abused, objectionable in principle, and should be abolished."

Correspondence

We do not hold ourselves responsible for the opinions of our correspondents.

THE "CANCER FOG."

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In pursuance of the promise in my previous letter I proceed now, with your permission, to offer a suggestion or two regarding the definition of a few of our terms, which may perhaps throw some light on the subject. Constitution, then! Is not constitution the resultant at any moment of the reaction between the organism and its environment from birth till the moment in question? Is not constitution, therefore, always in a state of flux, mobility, change, as the environment changes? I think so. Then heredity, on the other hand, is not that fixed and determined? Would not a good definition of heredity be that it was the state of the individual as determined by ancestors? It seems to me it would. And, therefore, the heredity remains fixed; what it was and is, that it remains, while the constitution is always altering and changing every moment. Constitution is the state of the individual as determined by environment. But to say that a constitution is altering and changing every moment, is equivalent to saying—is it not?—that a constitution may be non-cancerous at one period of its history, and cancerous at another. It seems so. A constitution may certainly be sound at one time, and damaged, broken, unsound at another, and this no doubt in response to changes effected on it by the envi-

ronment. A rheumatic fever will or may damage¹ a sound heart. The philosopher indeed may see that it was not so much the rheumatic fever which damaged the heart, as the previous course of events which led up to the occurrence of the rheumatic fever and of the heart damage which was one of the steps in the train of events. And similarly we have to inquire: May not long continued unsuitable and improper environment render a sound constitution epitheliomatous? Make it take on epithelioma? Make it cancerous? Why not?

This kind of question raises, of course, that other of predisposition. Well, what is predisposition? Is not predisposition at any moment very much the same as weakness? You sit in a draught and get a bronchial catarrh, but the draught was very slight and lasted for a very short time, and it ought not to have given you cold. But your predisposition was great; otherwise your resistance was low. Predisposition, therefore—is this a good definition?—is inverse resistance. But how did the predisposition become great? How did the resistance become weak? Not through heredity, for that is fixed and determined, and yet at one time you would not have taken cold from so slight a cause, while you do now. If not through heredity then, has not the change been effected by environment, otherwise by life history? And among facts of life history, what so important as relations to work, to air, and to food? and especially to the last?

Then as to what is inherited. Is it not so that organisation is inherited rather than disease? It seems to me it is. In a wide sense organisation is inherited; in a narrower sense, humanity, bovinity, vulpinity, felinity, are transmitted and inherited. Will it not depend on how humanity, bovinity, vulpinity, felinity are respectively treated—what conditions of environment they are subjected to—how or from what diseases they will suffer? Humanity will not suffer from bovine diseases nor from vulpine, though some diseases may be common to all forms of organisation. In fact, the possibility of using the term organisation at all implies some common qualities? From which considerations emerges a definition of the heredity of disease, viz.:—"Like causes acting on like organisms in succeeding generations induce like effects." How would that do? So that if a woman has cancer at 56, and her mother had cancer at 56, and her grandmother had cancer at 56, it would not at all follow that the grandmother transmitted it to the mother, and the mother to the daughter. We must first inquire how grandmother, mother, and daughter respectively lived, what environment they were subjected to, or what environment they subjected themselves to, before we can answer whether it was likely that each in turn transmitted cancer to her successor. Then as to the kinds of cancer. Is not one form far commoner than any other? Epithelioma, for instance. Suppose, for a commencement, we confine ourselves to that. Now, following the philosophic spirit so justly commended by Dr. Snow, let us ask a question or two here. Is not cancer, epithelioma, an overgrowth of tissue? It seems to me so. Where did it come from? It must have come as an exudation from the blood. It seems so. Where did the blood get it, or the stuff out of which it made it? Did, or could, the blood create it? Can the blood or the body create anything? We have no knowledge that it can or does. The body and the blood can convert, indeed, but so far as we can see they have no power to create. They must then have converted the epitheliomatous exudation or growth out of something else? Out of what did they convert it? What goes into the blood? Air, no doubt, or gases, and food. But especially food. Gases, as we know, pass in and out, but is it likely that solid growths are made out of air? They may be, of course; but is not food a far larger and more bulky entrant into the blood than air?

No doubt in the vegetable kingdom solid growths are made from the air. It seems as if trees and shrubs obtain the material for their large bulk, greatly from the air and particularly from the carbon which it contains. But do animals? Theoretically they might, of course, but practically animals do not live on air. They certainly appear to obtain nearly the whole of the material which goes to form their bulk from the food which they con-

sume. If, for instance, a man ingests half a pound of carbon daily with the expired air, and if he takes in a large amount of oxygen which he inspires, does he not obtain much more material for his body from the 2 lbs. or 3 lbs. or 4 lbs. of food which he consumes daily, and which, or much of which, he passes into his blood? It seems so. How would it do then, or would it not promise well, if we examined the food of those persons who form epitheliomatous growths, which reason and observation alike tell us they cannot create, but which they, no doubt, convert out of something else? As air is, no doubt, an entrant into the blood as well as food, I have no wish to withdraw attention from air, but for the present let us think of the food, and then, if we have not a sufficient answer, let us consider the air as a possible source of cancer. Well, now following up this line, we find that women suffer from cancer more than men. Half as many more women had cancer as men in 1897. Formerly, the proportions were greater. In 1868, the proportion of women to men suffering from cancer was more than two to one. In 1892, the preponderance of women over men suffering from cancer was only as five to three, not as six and seven-tenths to three, as in 1868; and in 1897, as Dr. Snow says, the preponderance was still less. Now, two or three questions arise here. First, is the preponderance of cancer in women over men due to their sex or to their habits? If to sex, it cannot be due to sex alone, because, though sex is not altering, the proportion of cancer is altering. Suppose we turn then to habit. In what respects do the habits of women differ from the habits of men? Would not every one say that they eat oftener? I think so. And that they take by preference dainty things like cakes and bread made up in various tempting ways, and confectioneries? It seems so. And that while they do not eat so much as men they eat oftener. And that looking at the habits of women in general as regards this question of the incidence of cancer does it not look as if pollaki-siteism, if not polysiteism is, or may be, a cause of cancer among them? It seems so. And that while pollaki-siteism is the principle, the property, amylo-siteism and glycho-siteism are the detail, the accident? It seems so. And if in each generation of women we see these food habits strengthening rather than weakening, is there not in this a sufficient cause, and true cause, apparent for the increase of cancer without betaking ourselves to the theory of hereditary transmission? It seems so. Besides that, if heredity is the cause, should we not expect that hereditary disease would appear early in life rather than late in life, since the nearer we are to our ancestors the more influence they must be supposed to exert on us? and the more remote we are from our ancestors the less the influence they will be likely to exert, and the greater the influence of our own environment? It seems so. But children scarcely suffer from cancer at all. Out of 20,358 deaths from cancer in England and Wales in 1892, only 103 occurred among children under five years of age. It does not seem as if heredity had very much to do with it.

These seem to me to be some of the questions which the logical and philosophic spirit, commended so justly by Dr. Snow, raise regarding this question of the incidence of cancer. There are more of them, many more; but your space and my time are limited. Let me ask one. The same logical and philosophical bent causes one to inquire why are men now suffering from cancer more than they did? Why is the preponderance of the proportion of female cancer continually diminishing? Why is the proportion of male cancer increasing? Well, are not the habits of men approximating to those of women? Are men much more in the open air now than women? Are they not more in offices, in factories, on the exchange than before? I think so. So that men's habits in offices and women's in houses are fairly comparable and not very different in principle? And what about food? Are not men's habits in this respect altering somewhat? Are they also not tending to poly-siteism and to pollaki-siteism like the women? What about their breakfast at eight, their crust of bread and a glass of beer at eleven, their dinner at one, tea at five, and supper about nine? Is not that pollaki-siteism as compared

with the three meals of their ancestors, who led an active out-door life which oxidised the material off in the fields, and in the open air much more than their more penned-up successors? And even, when three meals only form the diet-habit of men, is not digestion slower now, owing to the absence of abundant exercise than it used to be in former times? And is there not in the inquiry regarding food a very promising line of investigation regarding the causes of cancer?

And if poly-siteism and pollaki-siteism seem possible causes of epithelioma, what is the direction in which hope for cure is to be looked for? In the surgeon's knife? Is that likely? Is it likely that the effects of causes acting three, four, five, or six times a day for many years are going to be undone by a surgical operation, however brilliant and however extensive? That long acting vital causes involving changes in nutrition are going to be undone by a few bold strokes of the mechanical and skilful knife of the surgeon? Is it compatible with the logical and philosophical spirit commended to us to expect that? After the brilliant and skilful operation, will not the same causes continue to act? and to re-induce similar changes in other parts of the body, even if the bold and extensive operation has succeeded in removing all the disease? Is not, in fact, too much dependence on such methods the main reason why the lament of Sir William MacCormac is so mournfully in evidence, and why there has been so little progress in the treatment of these affections since the days of Hunter? Suppose that the methods of treatment are wrong? Does it not seem as if they are, since the progress is so little—since, in fact, the disease is increasing, as Dr. Snow says, both in incidence and mortality? Prosecuting the logical and philosophical method further, if we see some evidence that poly-siteism and pollaki-siteism are a main part of the cause of epithelioma, would it not be likely that oligo-siteism or even asiteism for a time might have some influence in preventing the spread, perhaps even in undoing the process of epithelioma? Of course the philosopher sees that this may or may not be. The causes may have been acting for too long a time for such a change to happen. A knowledge of causes may or may not enable us to cure a process. But it is essential to prevention, and it is a very hopeful line of inquiry that oligo-siteism, dis-siteism or mono-siteism properly quantified may perhaps or possibly be the means of preventing cancer.

I have said more than I meant, but not more than I think, nor so much by a good deal. The importance of the subject, the hopeless way in which it is regarded, a hopelessness which I by no means share, the mystery of it and the fascination of it must be my excuse.

I am, Sir, yours truly,

PHILOSOPHUS IGNOTUS.

THE IRISH "SCALE" FEE SYSTEM.

To the Editor of THE MEDICAL PRESS and CIRCULAR.

SIR,—The able article in your last issue bursts the bubble of special fees for poor people as a remedy for the abuse of the dispensary ticket system. Certainly no person having any practical knowledge of medical practice and medical remuneration in rural districts in Ireland could have expected it to be a success. As you clearly show, the Irish peasant argues that inasmuch as he pays a portion of the doctor's salary (one fourth part only under the new regulations), he is quite entitled to demand his services without further remuneration, however small, and in the few cases where dispensary doctors have been weak enough to agree to a reduced scale of fees, I fear they will soon find such fees will be the highest obtainable.

It is a matter for congratulation that the necessity for meetings to discuss these matters with each other seems at last to have roused the Poor-law medical officers to the need for combination, and in a good many Unions they have so combined to demand an adequate minimum remuneration for extra services. I regard such local combinations as the first and most necessary step towards obtaining a reform of those grievances of which they most justly complain.

I have long been of opinion that only two remedies

exist for the use of dispensary medical relief. Either pay the dispensary medical officers adequate salaries, and give every person in their districts the right to their gratuitous services, or else adopt the English system of preparing lists of those persons in the union whom the guardians should agree to be fit persons for free medical relief.

I cannot see that such a system would entail any hardship upon the poor, because the medical officer, would only have a consultative voice in the selection, and I believe it would save much heartburning and sense of injustice.

As I am not a dispensary doctor, my opinion is quite disinterested.

I am, Sir, yours truly,

T. H. MOORHEAD, M.D.

INTERNATIONAL CONFERENCE ON SYPHILIS AND VENEREAL DISEASES AT BRUSSELS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have just received a letter from Dr. Dubois-Havenith, secretary of the congress on venereal diseases to be held in Brussels from September 4th to 8th, asking me to write to the medical journals to enlist their sympathy in making the congress a success. The medical men who are at the head of this congress, viz., Professor De Smit, Dr. Janssens, and Dr. Bayet, are well known to many of your readers, and are a guarantee that the discussions are likely to be of service. Medical men, lawyers, and public functionaries are invited to take part in the congress, and I have but little doubt that many British medical practitioners will be anxious to give their opinion as to how syphilis might be prevented.

It is hoped that all shades of opinion may be expressed, and all difficulties candidly discussed, for it is lamentable that such an amount of preventible contagion should exist in civilised countries.

I am, Sir, yours truly,

CHARLES R. DRYSDALE, M.D.

Consulting Phys. Metropolitan Hospital of London, formerly Physician to the Rescue Society's Hospital.

London, July 14th, 1899.

Literature.

DE MERIC'S ENGLISH-FRENCH MEDICAL DICTIONARY. (a)

THE author of this new dictionary is to be congratulated on having filled a gap in medical literature, which has been felt for many years past on both sides of the Channel. There must necessarily be a large number of medical readers who require to have occasional recourse to a technical dictionary in a foreign language; yet, so far as our experience goes, no one previously has had the courage to tackle this difficult task, at any rate, in this form, for Maxwell's "Terminologie Medica Polyglotta," though very useful of its kind, cannot well take the place of a dictionary specially devoted to English-French medical terminology.

In criticising a work of this sort the reviewer is met with the difficulty that the scheme of the work may or may not meet with his approval. It may appear too brief or, as in this instance, unduly comprehensive. Perhaps the safer plan is to accept the author's scheme, and to criticise within the lines he has traced for his own guidance. In a dictionary proper we are only entitled to expect the corresponding equivalent in the other language of the selected terms, not an explanation of the meaning of the terms. Consequently, when we are given an explanatory phrase instead of an equivalent term as in the work before us we are to presume that no corresponding term exists in the French language. Fortunately, this is only needed in the case of terms little used

and less understood, such as *cataractem*, *catacleisis*, *celiopyosis*, &c., &c., but even here there are sometimes analogous French words—cataphoresis, for example.

No one is perhaps better qualified by virtue of parentage and natural associations to compile an English-French medical dictionary than Mr. de Meric, as one language is as much his mother tongue as the other. It is doubtless owing to that fact that we have been unable to detect orthographical or orthographical errors in either language. If it can be said to be a fault, there is perhaps a little hyper-sensitive anxiety regarding diphthongs, and also in describing or translating operations introduced by French surgeons or *vice versa*; but, taken as a whole, the author has performed his task conscientiously and well. We have no fault to find with the accuracy of the renderings which, without being copious, are sufficiently comprehensive. The labour which this work entailed must have been enormous, and when Part II. (French-English) has been published, the author will have deserved the thanks of medical readers on both sides of the Channel for the trouble he has taken to minimise, in some measure, the hindrance to the dissemination of scientific ideas created by the divergence in language.

ALLBUTT'S SYSTEM OF MEDICINE. (a)

THIS is certainly a most puzzling volume. It is divided into three parts:—1. Diseases of the Circulatory System continued from a previous volume. 2. Diseases of Muscles. 3. Diseases of the Nervous System, obviously incomplete and probably to be continued in the next instalment. Why one volume could not have been devoted to Diseases of the Heart and Lungs and another to Diseases of the Nervous System we do not know. A classification pretty much on these lines was adopted in the case of Reynold's System of Medicine, and was a success. Many people who are neurologists care very little about diseases of the circulatory system, and to have them all jumbled up in the same volume is not convenient. As originally planned, the System was to have been completed in five volumes and here we are, in the sixth volume, apparently almost as far off the end as ever. Whether it will be completed in one, two, or three more volumes we do not know. The editor is reticent and tells us nothing. But, although we complain, and we think not without reason, of editorial deficiencies, we have not a word to say against the individual articles, most of which are of a very high order of merit.

After an article by Dr. Newton Pitt on right-sided valvular diseases, based chiefly on the records of Guy's Hospital, we come to the subject of angina pectoris, which has been entrusted to Sir Richard Douglas Powell. It is a careful, scholarly, and painstaking article, but it is not very practical. He tells us nothing about treatment that we did not know before, and what little he does tell us is not quite up to date; in fact, the article might well have been written a couple of years ago. He seems to be very hazy as to the relative value of the vaso-motor dilators, and gives us no idea as to which to select in different stages of the complaint. He mentions erythrol tetranitrate incidentally, but says not a word about its explosive properties, or the dangers from its preparation or dispensing in a tabular form. More than one accident has attended its use, and even in a system of medicine something might well be said on the subject. Probably the author's best point is when he speaks of the Nauheim treatment as being so "boomed" into popularity for every conceivable form of heart disease and imaginary heart ailment as to discredit its use in appropriate cases.

The articles on Thrombosis and Embolism, by Prof. W. H. Welch, of Johns Hopkins University, are excellent, and were, perhaps, worth waiting for, although we do not think that the diagnosis between these two conditions is given very clearly.

Dr. F. W. Mott deals in a characteristically able manner with arterial degenerations and diseases. It is certainly

(a) "Dictionary of Medical Terms, Vol. I., English-French." By H. de Meric, M.B.C.S., Surgeon to the French Hospital, London, &c. London: Baillière, Tindall, and Cox, 1899. P.p. 304. Price 5s.

(a) "A System of Medicine." By many Writers. Edited by Thomas Clifford Allbutt, M.D., F.R.C.S., F.R.S. Vol. VI. London: Macmillan & Co., 1899.

a very good bit of work, and is one of the best in the volume.

The article on Aneurysm of the Aorta by Sir W. T. Gairdner is in the author's very best style, and is a credit to the Glasgow University. He speaks favourably of the Macewen method of introducing pins rendered aseptic into the sac so as just to touch the opposite wall, basing his opinion on an examination of his colleague's preparations. Professor Gairdner has evidently no high opinion of "Filipuncture," and we almost regret that he has not condemned so barbarous a method of treatment in more vigorous language. The modern surgeon who would treat an aortic aneurysm by the introduction into its sac of yards of wire or watch-spring would deserve severe condemnation, and would justly be accused of experimenting on his patient. A good account is given of the Tufnell treatment, or Bellingham and Tufnell treatment, as it is sometimes called, and the principles of the method are admirably stated. The claims of iodide of potassium to be regarded as something more than a palliative in cases of aneurysm receive full consideration, and credit is given to Dr. George Balfour for so persistently advocating the employment of large doses of this drug. A brief reference is made in a note to Professor Whitla's suggestion that chloride of calcium, from its marked influence on the coagulability of the blood, might be found useful in these cases. It would have been interesting to have learnt something of Sir William Gairdner's experience of the method of treating aneurysms in general, and of aneurysm of the aorta in particular by the subcutaneous injections of a gelatinous solution advocated by Lancereaux and Paulesco.

"There is a brief account by Dr. Hale White of Myotonia Congenita, a malady, the chief feature of which is that upon the execution of any voluntary movement the muscles brought into play remain contracted for some seconds. It is sometimes known as Thomsen's disease, after a Danish physician who suffered from it and first described it. Dr. Hale White seems to have had one case under his care, and Dr. Herschell some time ago showed at the Medical Society two brothers suffering from this disorder.

Dr. Beevor contributes the article on Idiopathic Muscular Atrophy and Hypertrophy, accepting as synonyms the terms primary progressive myopathy and progressive muscular dystrophy. He does not accept in this connection the name pseudo-hypertrophic paralysis which Sir William Gowers employed in his well-known lecture on the subject published in 1879, but recognises three principal varieties or groups, which he describes under the headings of (1) Pseudo-hypertrophic paralysis. (2) The juvenile form of progressive muscular atrophy. (3) The facio-scapulo-humeral form, an arrangement which somewhat complicates matters. It is curious that an article of such value and originality should not have been illustrated, as children suffering from the affection lend themselves readily to photography, and the results are usually most characteristic.

The article on the General Pathology of the Nervous System by Dr. Bevan Lewis, is admirable, and will be found of the greatest possible value to readers who are unfamiliar with the most recent discoveries in the physiology of the nervous system. He explains very fully and clearly the modern conception of the neuron, axon, dendrons, and other matters which are essential to a clear understanding of the pathology of the nervous system. This article alone is a liberal education in the study of diseases of the nervous system.

The article by Dr. Turnay, on Trophoneurosis or neuro-pathic affections of bones and joints deals fully with osteopathies, arthropathies, and osteo-arthropathies, and is a useful contribution.

The editor touches lightly on Adiposus Dolorosa, a disorder characterised by irregular, sometimes symmetrical deposits of fatty masses in various portions of the body preceded by or attended with pain. It is simply a clinical curiosity or "freak," and hardly merits serious consideration.

Dr. Barlow is a well-known authority on Raynaud's disease or symmetrical gangrene, and his contribution

will be read with interest. The credit of having first described this disease is usually assigned to Maurice Raynaud, whose original thesis and a subsequent paper were translated by Barlow and published in 1888 by the New Sydenham Society. Cases are by no means uncommon in this country, and one or two typical examples are usually to be found in most of our London hospitals. The article on Erythromelalgia has also been entrusted to the same author, and we are glad to find that he has taken the trouble to give the derivation of the word, an example which might have been followed with advantage by other contributors.

The subject of Tendon Reflexes has been dealt with by Dr. Sharkey, who has made the most of a very interesting and practical subject. The article on Diseases of the Spinal Nerves by Dr. Gibson and Dr. Fleming is accompanied by a useful table of the spinal segments with their nerves and muscles. In conclusion, we can only repeat that the individual articles are of a very high order of merit.

EASTBOURNE AS A HEALTH RESORT. (a)

This small work is well printed and got up, and cannot fail to interest and instruct anyone contemplating a visit to Eastbourne. Those who dread the easterly winds of Eastbourne must remember that these are not dry and harsh; but coming down the Channel are tempered by passing over the warm sea water.

The water-supply of Eastbourne appears now to be pure and wholesome, though hard, as waters from the chalk always are.

The author clearly explains the cause of the Eastbourne water being at one time under suspicion. He does not slide over the matter in a way likely to leave the reader in doubt and suspicion, but explains all in a way that is clear and reassuring.

Tables of temperature, &c., of course, are to be found in this as in all local works on climate. We often wonder which, after all, is the place that really does enjoy most sunshine on the South Coast.

Eastbourne, like Hastings, has a strongly marine air, and this most certainly is in its favour as a health resort in tuberculous disease of the lungs.

HOGG ON THE MICROSCOPE. (b)

THE value of this work, the first edition of which appeared in May, 1854, is sufficiently evidenced by the fact that the edition now under review is the fifteenth. The present work is divided into two parts and an appendix.

Part I. begins with an interesting account of the early history of the microscope. Chapter I. is devoted to the theories of light in their application to the subject in question; Chapter II. gives an up-to-date synopsis of the various types of microscope, not omitting the most modern developments of the instrument; in Chapter III. we find excellent accounts of those most essential microscopic accessories, such as achromatic objectives, condensers, finders, &c., together with an account of micro-photography, the polarisation of light, and the micro-spectroscope. Chapter IV. is devoted to an account of the practical execution involved in preparing, examining, and preserving all kinds of microscopic objects.

Part II. is divided into six chapters, and comprises an account of practically every possible kind of microscopic object that can attract the attention of the student, the medical practitioner, or the analyst. The portions dealing with the various parasites attacking members of both the animal and vegetable kingdom are remarkably comprehensive and lucid.

The work throughout is most lavishly illustrated both

(a) "Eastbourne as a Health Resort." By Charles Roberts, F.R.C.S., &c. Eastbourne, J. Pulsford. 1899.

(b) "The Microscope, its History, Construction, and Application." By Jabez Hogg, M.R.C.S., F.R.M.S. George Routledge and Sons, Limited, London and New York. 15th edition, re-written, revised and enlarged throughout, 704 pp., with upwards of 900 engraved and coloured illustrations.

with engraved drawings and with coloured plates, and apart from the intrinsic value of the information afforded, is written in so readable a manner that it presents a powerful attraction for every intelligent lover of nature.

A melancholy circumstance in connection with this last is the fact that its distinguished author, who was for many years on the staff of this journal, died suddenly within a few days after revising the proof sheets of the work for the press.

Medical News.

Royal College of Surgeons in Ireland.

THE following is a list of prize winners in the school of the Royal College of Surgeons of Ireland during the Summer Session, 1899:—

Carmichael Scholarship.—Miss M. J. Shire, £15. **Mayne Scholarship.**—D. A. Fitzgerald, £15. **Gold and Silver Medals in Operative Surgery.**—C. E. Boyce, gold medal; C. Myles and J. F. Peart (equal), silver medal. **Practical Histology.**—E. Evatt, first prize (£3) and medal; A. Charles, second prize (£1) and certificate. **Practical Chemistry.**—E. C. Byrne and J. E. H. M'Manus (equal), first prize (£2) and medal. **Public Health and Forensic Medicine.**—J. P. Byrne, first prize (£3) and medal; E. Evatt, second prize (£1) and certificate. **Materia Medica.**—J. S. Ashe, first prize (£3) and medal; T. A. Dillon, second prize (£1) and certificate. **Practical Pharmacy.**—Miss J. C. Hargrave, first prize (£3) and medal; W. Ormsby, second prize (£1) and certificate. **Biology.**—J. R. B. Buchanan and Miss J. C. Hargrave (equal), first prize (£2) and medal.

The preliminary examination for the commencement of medical study will be held on Wednesday and Thursday, September 27th and 28th.

ON the list of Fellows and Licentiates of the Royal College of Surgeons in Ireland, just issued, are living at the present time 382 Fellows, 11 Honorary Fellows, 2,746 Licentiates, 84 Diplomates in Public Health, 7 Honorary Diplomates in Public Health, and 517 Licentiates over different parts of the world. Several hold commissions in the Medical Department of the Royal Navy, and in the Home and Indian Army. A considerable number enjoy a European reputation. Amongst those holding titular honours are one peer, four baronets, two K.C.B.'s, eleven knight bachelors, thirteen military C.B.'s, two C.M.G.'s, one K.C.V.C., eight D.S.O.'s, and two hold the Victoria Cross, awarded for "conspicuous bravery in the presence of the enemy," their names are, Major J. Crimmin, of the Indian Army; and Lieutenant Colonel W. Temple, of the Royal Army Medical Corps.

Oral Instruction for the Deaf.

THE annual meeting of this Association for the Oral Instruction of the Deaf was held on the 11th inst. under the presidency of Mr. Brudenell Carter, F.R.C.S. A public examination of the pupils was given, an illustration of the system given, and prizes distributed to the successful students. The Association has been doing a most useful work for the past thirty years under the direction of Mr. Van Praagh, but its efficiency has been much hindered by want of funds. It would appear that because deaf and dumb children are not ill, the public do not look on them as needing pecuniary support, hence a very deserving charity which carries on its work in an unobtrusive way is left to starve. An appeal is now earnestly made for assistance to the extent of £1,000, and we sincerely hope this sum may be obtained. The school is carried at 11, Fitzroy Square, London.

Society for Relief of Widows and Orphans of Medical Men.

THE Quarterly Court of the directors of this Society was held on Wednesday last, July 12th, the Treasurer, Dr. Potter, in the chair. Four new members were elected and the deaths of three reported (one an honorary member). There were no fresh applications for grants, and it was resolved that a sum of £1,201 10s. be distributed, as recommended at the last courts, to the forty-nine widows, ten orphans, and the six recipients

from the Copeland Fund. The expenses of the quarter were £49 8s.

West London Medico-Chirurgical Society.

THE following officers and members of Council of this Society for 1899-1900 were elected on Friday last July 14th:—President: *Dr. J. Barry Ball. Vice-Presidents: Mr. C. M. Tuke, Mr. L. A. Bidwell, *Dr. Seymour Taylor, *Mr. Neville Wood. Council: Dr. Andrew Elliot, Dr. F. H. Low, Dr. J. Harper. Mr. C. Andrews, Dr. F. J. McCann, Mr. F. R. Mallard, Mr. F. Savery, *Dr. L. Dobson, *Mr. E. Bartlett, *Dr. D. R. Pearson, *Mr. H. W. Chambers, *Mr. G. E. Twynam. Treasurer: Mr. T. Gunton Alderton. Secretaries: Dr. G. D. Robinson, *Dr. G. P. Shuter. Librarian: M. C. B. Keetley. Editor of Journal: Mr. H. Percy Dunn. Editorial Secretary of Journal: Mr. McAdam Eccles. *Did not hold similar office last year.

The Surgical Aid Society.

THIS unobtrusive but very useful society continues to extend its sphere of usefulness, and has once again enlarged its premises in Salisbury Square. The opening of the enlarged premises was last week the occasion of a little fête which was presided over by Lord Aberdeen.

Death Under Chloroform.

THE death of a young collier under chloroform, while undergoing an operation for appendicitis, is reported from Cardiff Infirmary. Death seems to have been due in great measure to the man's condition, which was exceedingly grave.

Relics of the Late Mr. Ernest Hart.

THE late Mr. Ernest Hart was a born collector, and among other things he went in for the now fashionable "picture posters." His collection is announced for sale this week. *Adis aur amateurs!*

The Plague at Alexandria.

THE Sanitary Officials are still on the alert at Alexandria. Up to the end of last week the total number of cases amounted to 69, with 28 deaths. There were, however, only three new cases during the preceding week.

Manila Medical Statistics.

ACCORDING to the official report just published regarding the medical condition of the army in Manila there are no less than 1,388 soldiers down with malaria, dysentery, typhoid, and wounds. The total number of wounded up to date is put at 1,586, exclusive of 292 dead. The total number of men in hospital is 1,889. Our cousins will have learned ere this that colonial wars are not all beer and skittles, and they will learn to appreciate the importance of an efficient army medical department.

The Paris International Medical Congress, 1900.

A MEETING of the National Committee for Great Britain and Ireland, which has been formed to further the interests of this Congress, was held at the rooms of the Medical Society, 11, Chandos Street, Cavendish Square, W., on Tuesday, July 4th, 1899, Sir William MacCormac, Bart., K.C.V.O., President of the Royal College of Surgeons of England in the chair. The rules, regulations and preliminary agenda of the Thirteenth International Congress were presented, and were ordered to be distributed among those likely to be interested in the meeting. It was decided, after some discussion, that Messrs. Thomas Cook and Co., tourist agents, be asked to arrange for the conveyance of intending members of the Congress, and, failing any satisfactory arrangements by the local committee in Paris that the same firm be invited to find accommodation. The honorary secretaries (Dr. A. E. Garrod, 9, Chandos Street, Cavendish Square, W., and Mr. D'Arcy Power, 10a, Chandos Street, Cavendish Square, W.) were authorised to receive the fee (£1) for membership, and they were directed to inform those members who wished to make a communication to the Congress that papers should be sent straight to the sectional secretaries in Paris.

Notices to Correspondents, Short Letters, &c.

✍ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

LOCAL REPORTS AND NEWS.—Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sending them to the Editor.

ACCEPTED PAPERS.

To the list published in our last issue should be added the following:—

CHRONIC FOLLICULAR PHARYNGITIS. By Robert H. Woods, M.B., F.R.S.

THE OUTDOOR TREATMENT OF CONSUMPTION IN LARGE CITIES. By David Somerville, B.A., M.D.

AGGRIEVED.—If you will supply us with data on which we can found an opinion we shall be pleased to give it. The purchase of a practice is at all times a hazardous business, and where possible should not be determined until a qualified accountant has checked the books and figures. The calculations of interested agents should never be relied on.

THE OFFICIAL SCHOOLMASTER ABROAD.—A Government officer in Burma recently wrote the Chief Vaccination Officer at Rangoon as follows:—"Please send sharp a *cast* of 'vaccine lymph.'"

A MISCONCEPTION.

"I CAN'T conceive," she archly cried,
"Wherein you men can longer pride
Yourselves from female rivals free,
For surely we have grown to be
Your peers in every human stride."

"That is a truth that none may tride;
So why you men will not decide
To recognise the new degree,
I can't conceive."

"Now *entre nous* won't you confide
And tell me true, all jokes aside,
What difference the world can see
Between your manly self and me?"

"To tell you truly," he replied,
"I can't conceive."

New York Medical Journal.

HYPONOTIST.—The communication should be sent to the Chief Commissioner of Police, New Scotland Yard, S.W.

ANASARCA (Birmingham).—The subject was fully discussed in our pages at the time, and no good purpose would be served by reopening it just at present.

M.D., M.R.C.P.—Our correspondent has failed to enclose his card.

WHAT THE HUMAN BODY WILL YIELD.

A FRENCH statistician has calculated that the average human body contains enough fat to produce thirteen pounds of candles; enough carbon to make sixty-five gross of "lead" pencils, and sufficient phosphorus to tip 820,000 matches. Perhaps he will complete his observations by calculating how many bone-handled knives one body would furnish, how many watch-springs could be made from the iron in the blood, and how much mortar could be made from the lime contained in the tissues. When he has done this we will suggest sundry other as yet unsolved problems.

Appointments.

BARROW, GEORGE A., M.R.C.S., L.R.C.P.Lond., Assistant Medical Officer to the Manchester Hospital for Consumption.

BOYD, Dr. F. D., Assistant Physician to the Edinburgh Royal Infirmary, vice Prof. Leith resigned.

BLOOD, J. F., M.D., Surgeon-Major, I.M.S. (retired), Surgeon to the Birkenhead Borough Hospital.

CATLEY, F. P., L.R.C.P.Lond., M.R.C.S., Assistant Medical Officer for the Workhouse of the Parish of St. Pancras, London.

DRAKE, E.C., L.S.A., Medical Officer to the Tudhoe Sanitary District of the Durham Union.

DU BUISSON, E. W., L.R.C.P.Lond., M.R.C.S., Medical Officer for the Dewchurch Sanitary District of the Hereford Union.

GARMAN, F. W., Assistant House Surgeon to the Dental Department at Guy's Hospital.

HALL, ARTHUR J., B.A., M.B.Cantab., M.R.C.P., Professor of Pathology in University College, Sheffield.

HARRISON, H. F. E., L.R.C.P.Lond., M.R.C.S., Medical Officer for the No. 3 Sanitary District of the Fulham Union.

HAYDON, HILLYARD, WILLIAM, L.R.C.P.Lond., L.S.A., M.R.C.S., Medical Officer of Health for the Wadebridge Urban District.

HORNE, W. JOHNSON, M.B., B.C.Camb., Surgeon to the Metropolitan Ear, Nose, and Throat Hospital, Fitzroy Square, London.

LAKE, RICHARD, F.R.C.S.Eng., Surgeon to the Metropolitan Ear, Nose, and Throat Hospital, Fitzroy Square, London.

LANDSOWN, C. E., M.R.C.S., L.R.C.P.Lond., Surgeon to the Hospital for Sick Children, Cheltenham.

LAWRENCE, H. GWYNNE, L.R.C.P.Lond., M.R.C.S., Medical Officer of Health for Chepstow.

LAWSON, THOMAS CORNELIUS, M.R.C.S., L.S.A., Medical Officer for the Coleford District of the Frome Union.

LEAF, CECIL H., M.A., M.B.Cantab., F.R.C.S.Eng., Assistant Surgeon to the Cancer Hospital, Fulham Road, Brompton.

MORISON, F. H., M.D.Edin., D.P.H.Irel., Medical Officer for West Hartlepool.

OLVER, S. H., L.D.S.Eng., House Surgeon to the Dental Department at Guy's Hospital.

RECORDON, R. B., Assistant House Surgeon to the Dental Department at Guy's Hospital.

REID, J., M.D., C.M.Glasg., Medical Officer for the No. 1 Sanitary District of the Fulham Union, London.

Vacancies.

Borough Asylum, Portsmouth.—Junior Assistant Medical Officer. Salary commencing at £120 per annum, with board, lodging, and washing.

Bradford Poor-law Union.—Resident Assistant Medical Officer for the Hospitals and Workhouse of the Union. Salary £100, with rations, &c. Apply to the Clerk to the Guardians, Bradford.

County Down Infirmary. Registrar, Assistant-Surgeon, and Apothecary. Salary £63, with board, lodging, washing, &c. Applications to Dr. Tate (See advert.).

Durham County Hospital, Durham.—House Surgeon for one year. Salary £100 per annum, and board and lodging.

Galway Hospital.—House Surgeon. Honorarium £30, with apartments, board, washing, and attendance. (See advert.).

Govan District Asylum, Crookston, near Paisley, N.B.—Junior Assistant Medical Officer. Salary £100 a year, with furnished rooms, board, washing, and attendance.

Hertford Union.—District Medical Officer for Second and Third Districts. Salary for the combined districts £79 16s., exclusive of usual extras. Immediate applications on forms supplied by the Clerk to the Board. (See advert.).

Lunatic Hospital, The Coppice, Nottingham.—Assistant Medical Officer, unmarried. Salary £150 a year, with apartments, board, attendance, and washing.

Metropolitan Asylums Board.—Assistant Medical Officer at the New Grove Hospital, Tooting, S.W., unmarried. Salary commencing at £160 per annum, with board, lodging, attendance, and washing. Applications to the Clerk to the Board, Norfolk Street, Strand, London.

Ramsgate and St. Lawrence Royal Dispensary, and Seamen's Infirmary. Resident Medical Officer, unmarried. Salary £100 per annum, with furnished apartments, board, and attendance.

Roxburgh District Asylum, Melrose.—Assistant Medical Officer. Salary £100 per annum, with furnished apartments, board, washing, and attendance.

Somerset and Bath Lunatic Asylum, Wells, Somerset.—Junior Assistant Medical Officer, unmarried. Salary commencing at £120, with board, washing, &c.

Staffordshire County Asylum, Stafford. Junior Assistant Medical Officer, unmarried. Salary commencing at £120 per annum, with furnished apartments, board, &c.

Surrey County Asylum, Brookwood, near Woking.—Temporary Assistant Medical Officer for about four months. Salary at the rate of three guineas per week with apartments and all found. Apply to the Medical Superintendent.

Swinford Union.—Medical Officer, for a month, for the Lowpark Dispensary District. Applicants to state remuneration expected. (See advert.).

West Sussex County Asylum, Chichester.—Junior Assistant Medical Officer, unmarried. Salary commencing at £100 per annum, with furnished apartments, board, attendance, and washing.

Births.

BAKER.—On July 12th, at 5, Bedford Square, London, the wife of John H. Baker, M.D., of a daughter.

ELGOOD.—On July 14th, at Windsor, the wife of Charles Elgood, M.D., B.Ch.Lond., of a daughter.

HOUSEMAN.—On July 14th, at Houghton-le-Spring, Durham, the wife of J. G. Houseman, M.D., of twins.

Marriages.

COLCLOUGH-JAMES.—At Broadbentbury Church, near Honiton, W. Frank Colclough, B.A., M.B., B.C.Cantab., &c., Medical Officer to the British Hospital, Oporto, Portugal, to Florence Irene, fourth daughter of the late W. Rhodes James, of Pinhoe, near Exeter.

FAWCETT-BAXTER.—On July 15th, at St. Paul's Church, Hampstead, John Fawcett, M.D., M.R.C.P., Assistant Physician to Guy's Hospital, to May Fleming, younger daughter of H. Fleming Baxter, of Hampstead.

WALLIS-MILNES.—On July 11th, at St. Martin's Church, Werrington, Albert William Wallis, M.R.C.S., of Brentwood, Essex, to Ada Fannie, eldest daughter of the late William Stert Milnes, of Yeolmbridge, near Launceston, Cornwall.

Deaths.

ADAMS.—On July 14th, at the Lawn, Martock, Somerset, Annabella, wife of I. Dixon Adams, M.D.

BAILEY.—On July 8th, at his residence, Bromley, Kent, George Hewlett Bailey, M.R.C.S., &c., late of 43½ Queen Anne Street, W., London, aged 71 years.

NEWHAM.—On July 12th, James Newham, M.R.C.S., of 80 Gloucester Place, Portman Square, London, and Doddington, Cambs., aged 74.

A Clinical Lecture

ON

DISEASES AFFECTING THE NAILS.

DELIVERED AT THE LONDON HOSPITAL.

By JONATHAN HUTCHINSON, F.R.C.S., F.R.S.,

Consulting Surgeon to the London Hospital, and to the Royal London Ophthalmic Hospital; Senior Surgeon to the Hospital for Skin Diseases, Blackfriars.

GENTLEMEN,—I have chosen to approach this subject from the point of view taken in my title rather than from that of the nail disease as the starting point, as tending to clearer views of this perplexing subject, and because I believe that a large proportion of such diseases are merely extensions to the nails of processes beginning in other parts of the system and regions of the skin. And the first rule which I wish to lay down is that the character of nail-lesions will depend not only upon the original disease of which they are an extension, but also upon the thickness and strength of the nail itself. The thicker the nail the more distinct usually are the lesions.

I wish first of all to call your attention to certain marks and grooves upon the nails which mark the date of some severe attack of illness, because here the problem is of the simplest and the causation unquestioned. These vary, as you will see by these portraits from transverse, white lines curving across the substance of the nail, to deep grooves and even hæmorrhagic stripes, due to the effusion of blood into the nail-substance. Here is a water-colour drawing of the hand of a young man who had a number of similar attacks, causing the development of broad transverse grooves across all his nails, most clearly seen on that of the thumb, and which invariably followed curious "bilious" attacks, which came on with headache, loss of appetite, bad tongue, and all the symptoms of hepatic catarrh except actual jaundice. These produced a curious form of muscular stiffness in his limbs, almost amounting to paraplegia in certain groups of muscles. This would last for a week or more, and each one be followed by these broad marks across the nails. This is one of the first cases in which I had observed the occurrence of actual deformation of the nail substances from such a cause, and illustrates admirably the profound disturbance of nutrition produced in that portion of the nail-root which is growing most actively at the time of the attack of illness.

Here is another drawing which illustrates the formation of white lines across the nails as a result of illness, in this case most marked upon the little finger. These are by no means uncommon, especially after febrile or gouty attacks, but appear to bear no relation to the severity of the illness. In both these conditions the occurrence of the lesion appears to depend largely upon the structure of the nail, as in most cases it is only upon thick, strong nails that they appear at all, thin, brittle nails seeming to be largely exempt.

* This drawing shows a very striking case of pigmental lines across all the nails, due to hæmorrhage into the nail substance consequent upon successive

paralytic or extension of paralysis attacks in a paralytic woman. These originally developed at the root or growing portion of the nail in or near the lunula, travel down the nail as this cross-level "grows out" to the free edge, which they ultimately reach, and are shed. This may be easily seen in injuries or trappings of the base of the nail severe enough to produce hæmorrhage, the resulting mark steadily travelling along the nail till it "grows out." Any severe disturbance of the circulation may cause these discolorations. Then there are certain forms of disturbance which result in the formation of longitudinal markings or ridges down the middle of the nails, though as to the nature and causation of these we are quite in the dark. A red central elevation begins at the edge of the lunula and travels down the nail so that an elevated central ridge results, then the nail becomes thin and brittle at its edge and borders and begins to crack and scale off, and ultimately is entirely destroyed. The disease persists for years and is quite uncontrollable, and while it causes no pain, is most annoying on account of the hard unsightly red tips left upon the fingers after the destruction of the nails. I have here several drawings illustrating this annoying condition, two of them showing a curious variation in which the longitudinal ridge takes a wedge or fan-shape with the apex forward, and which I have ventured to term on this account "pterygium" of the nail. Both of these occurred in young people, who also suffered from lupus and eczema, but the disease ran its usual course, and destroyed the nails almost completely.

The two great groups of skin diseases which we term psoriasis and eczema have each their characteristic mode of affecting the nails. These may be roughly distinguished by saying that psoriasis usually attacks the free border and nail-bed and under surface of the nail and spares the upper surface, while eczema generally attacks the root and folds of the nail and roughens and pits the upper surface.

In these drawings you see there is inflammation of the nail bed extending under from the free or distal margin, loosening the nail at its tip and often accompanied by an accumulation of epidermal scales beneath the nail so that a pin or fine probe can be pushed up easily under the nail half or threequarters of an inch. The top of the nail remains smooth, and its substance is little affected.

Although not an uncommon symptom in the course of general psoriasis, this form of nail disturbance may be the only symptom of the disease, and its nature is then proved by its yielding promptly to arsenic. I have frequently seen this condition, the only symptom in a patient, other members of whose family had well-marked psoriasis of other parts of the skin. Only recently a girl was brought to me with this as the only lesion, and upon inquiring as to her father's condition, he pulled up his sleeve and showed me well-marked scaly patches on both elbows.

In eczema, on the other hand, the disease begins at the root or folds of the nail and affects its substance and surface much more severely. Longitudinal thickenings and furrows are often produced, the nail is opaque and dirty-looking, and its surface rough, often stippled all over as with a series of shallow pin-pricks. It is a much more serious and

disfiguring disease than psoriasis of the nail, but the two conditions not infrequently co-exist, especially in those cases in which both eczema and psoriasis are present upon the body, the so-called "mixed" cases of skin-disease. Here is a drawing of the nails of a young lady who presented this "mixed" condition. As you see, the nails are rough, thickened, opaque and marked by longitudinal furrows. In this disease it is again most important to estimate the original condition of the nail, as it is a most influential factor in determining the character of the changes. The thick nail suffers more severely than the thin.

There is a form of senile psoriasis of the nails, fortunately quite rare, which is extremely severe. Spreading from the nail-bed, it causes ulceration of the finger-tips and even leads to gangrene. It also affects the toes, and in two cases the degree of soreness produced was so great that patients were quite unable to walk. Indeed so violent is it, that we could hardly believe it to be psoriasis, were it not for the characteristic scaly patches upon the body and limbs which usually precede it.

In clubbed fingers the nails are greatly enlarged, both in length and breadth, while in acromegaly the fingers are enlarged, but the nails are unaffected. This may be used as a diagnostic point in discriminating between the two conditions.

Of syphilis of the nails the chief thing to be said is that it presents an infinite variety of forms. There is no disturbance of them which it will not imitate. It often produces thick, fibrous ribbed nails; again, it imitates psoriasis and, in other cases, superficial erosions, like the pitting of eczema develop. They seldom permanently injure the nail substance or deform the nail, and they yield, though slowly, to mercury.

There is a pustular disease, of unknown origin, which attacks the nails of children. Red spots appear in the nail substance, form minute abscesses, and break through the surface of the nail. These pustules appear in crops, and are quite liable to recur several times. Ringworm affects the nails at times in a very similar manner, painful spots appear in the nails, and then pustules form which break through the surface. As a rule, only one nail is affected at a time, and the disease spreads slowly and obstinately from one nail to another. This, when it does occur, is so constantly associated with characteristic ringworm of the scalp or body, that I feel quite sure as to its nature, although I have always found the greatest difficulty in discovering or demonstrating the fungus in the nail substance itself. But this in my experience, is true of all parasitic diseases of the nails.

Another rare, but most destructive disease of the nails is congenital pemphigus. This leads to the complete exfoliation of the nail and a most unsightly deformity of the finger-tips, and may be recognised by the presence of the characteristic bullæ upon the digits, forearms and legs; these seldom or never extend above the elbow or the knee. I show here drawings of the hands of a mother and son, which could scarcely be distinguished from each other, and the disease often runs in families, in this particular group, the mother and three sons were all attacked. The disease is chronic, extremely obstinate, and treatment is of no appreciable effect.

Mr. MAGUTH, the ex clergyman, now medical botanist, who stands charged with manslaughter, in that he treated for simple sore throat a child who proved to be suffering from diphtheria, and subsequently died therefrom, has been duly committed for trial, bail being allowed.

A COUNTRY HERBALIST'S CURE FOR THE "KINGS EVIL." (a)

By JOHN KNOTT, M.A., M.D., and Dip. Stat. Med
(Univ. Dub.); M.R.C.P.I., M.R.I.A.; &c. &c.

[(Continued from page 57.)]

I HAVE NOW, I think, placed sufficient evidence before my readers to show the high reputation which the herbs in question possessed during many centuries in the treatment, not only of the dreaded King's Evil, but of many of the other physical ills to which human flesh is heir. I will now digress for a time for the purpose of displaying the reputation of other remedies—many of which are now totally forgotten or absolutely neglected—in the treatment of the special malady which has so much troubled the therapeutists of all the ages. In the "New London Dispensatory," compiled by William Salmon, the author of the *Herbal*, from which I have already quoted so largely, we find the following—

"Artanite, Cyclaminis, of sow-bread, hot and dry in 3°. A plaister made thereof with hog's lard and Sulphur, helps the Atheromata, Scrophula, and Kings Evil."

"Asari of Asarabacca. Hot and dry in 3°. The root is hotter, but a safer purge than the leaves. . . . It dissolves Wens and hard swellings, and is eminent against the Kings Evil, long tedious Quartan Agues, Green Sickness, and Asthma. . . ."

"Bardane majoris, Lappæ maj. Of the great Burdock, Temperate. . . . In the Gout and Kings-Evil it is a specifick."

"Chelidonii minoris, Scrophulariæ, of Pilewort, it is temperate. . . . Outwardly in a balsam, it Cures the Piles in the Fundament, Wens, Kings Evil, Sores and other creeping Ulcers. . . ."

"Jalapæ, Mechoacanæ nigra, of Jalap. Temperate and dry in 1°. It pumpeth strongly all bad humours, chiefly those that are watery, with great safety. . . . I have oftentimes found it a good specifick in Struma or the Kings Evil. . . ."

"Mecoacanæ albæ, of Mechoacan, or Rhubarb of Peru. . . . Temperate and dry in 1°. It is good in the Rickets, Scurvy, Kings evil, Catarrh's, Dropsies, Jaundice, Gout, and French Pox. . . ."

"Spatulæ foetidae, of stinking Gladdon, hot and dry in 3°. . . . taken in the morning fasting in Rhenish Wine, it prevails against the Cachexia, Dropsy, Kings Evil. . . ."

"Bardana minor, Lappa minor, *Εαρίθιον*, the lesser Burdock; hot and dry in 1°. . . . Outwardly it is of excellent use in the Kings Evil. . . ."

"Capparis, *Κάππαρις*, Capers; hot in 1°, and dry in 2°. . . . An extract of the Bark of the Roots. . . . very prevalent against Quartan Agues, hard Spleens, Kings Evil, Palsies, Convulsions, Cramps. . . ."

"Cotyledon, Umbilicus veneris, Acetabulum, *Κοτυλιδών*, Navil-wort, or pennywort; cold and moist in 1°. . . . The Essence prevails against the Sciatica and Kings-Evil."

"Cyclamen, Cyclaminus, Artanita, Sow-bread; hot and dry in 3°. The Juice of the Leaves (or rather their Essence) . . . or in a Balsam, warts knots, hard tumors, and swellings of the Kings Evil."

"Digitalis, Alisma, *Θαλλίς*, Fox-glove, hot and dry in 2°. . . . is an extraordinary good wound-herb, prevalent against the Kings Evil. . . ."

"Ebulus, Chamæcte, *Χαμαιακτὴ*, Dane-wort, or Dwarf-Eider, hot and dry in 3°. . . . The Essence . . . kills Worms, helps dry Coughs, Quinsies, Asthma's, King's Evil and French Pox. . . ."

"Eryngium trifolium, Trefoil Thistle; . . . opens obstructions of the Liver and Spleen, helps the Jaundice, Dropsie, Sciatica, French Disease, and Kings Evil."

"Ficaria, Scrophularia major, Figwort . . . hot and dry in 3°. . . . a good specifick in the Kings Evil."

(a) An abstract of this paper was read in the Medical Section of the Royal Academy of Medicine in Ireland on Nov. 18th, 1898.

"Fumaria vulbosa, Bulbous, or Onion-Fumitory; hot in 2°, dry in 3°. . . . It is . . . of singular force against the Kings Evil."

"Genista, Spartum *Ἰσίδρου*, Broom, hot and dry in 2°. It opens, attenuates, is abstersive, diuretick, hepatick, splenetick and nephritick . . . a great Traumatick and Vulnerary, and a Specifick in the Kings-evil."

"Hordeum, Distichon, Polystichon, *Κριθή*, Barly; cold and dry in 1°. . . . with Tar, Wax, Oyl, and Boys urine, it is effectual against the Kings Evil."

"Paronychia, Reduvia, *παρονυχία*, Whitlock-grass, hot and dry in 3°. . . . experience has confirm'd it to be a great specifick in curing of the Kings Evil."

"Primula Veris, Of the Primrose. The Flowers boyled in Vinegar and applyed, are good against the swellings of the Throat, Uvula, and Kings Evil, especially as a Gargarism."

"Rhamni, Spinæ Cervinæ fructus, Buckthorn Berries, hot and dry in 2°. . . . they are of great force against Cachexia, Dropsies, Jaundice, Gout, and Kings Evil."

The products of the Animal Kingdom were also laid under contribution, although not so extensively. We are, for instance, told that: "Talpa, The whole Mole, the Ashes of it helps. . . ." "Coluber . . . The Adder . . . the Ashes are good. . . ." "Hoglice . . . are most admirable things, being given 100 days together or more, for the curing of all sorts of Cancers and Scirrhus Tumors in what part of the Body soever, the King's Evil, old sordid and rebellious Ulcers, Convulsions, the Rickets in Children, and dimness of sight, yea blindness itself. I have also seen a very good effect of them being used for many days in the Cure of the French-Pox, for they resolve, cleanse and purify to a Wonder."

Of the number of mineral preparation recommended in the same volume for the cure of the King's Evil, I will mention but a few of those to which specially wonderful virtues were attributed.

"Manna Mercurii. Golden Panchymagogen. . . . This is a great specifick and Secret against the French Pox, Gonorrhœa, and all manner of Venereal evils, it eases pains in all parts. . . . and is made of wonderful Virtue for curing of the Kings Evil. . . ."

"Tinctura florum Reguli Antimonii. . . . It is a Medicine of that universal purport that few can parallel it; for it rectifies most Distempers of the Stomach, frees the body from Excrements, it takes away Flegm, comforts the Spi its, restores and augments the natural heat, is an admirable thing against the Scurvy, Cachexy, and the Green-sickness in Virgins: It takes away Scabs, Itch, Scurff, and Morphew, cleanses the whole Mass of blood of all putrefaction, and cures the Kings-Evil, Leprosy, and French Pox."

"Oleum Arsenici Anodynum. . . . It is an excellent thing against all poisoned Wound, Ulcers, and Cankers, Pocky boyls, sores, and breakings out, Kings-Evil sores, bitings of Mad-Dogs, Fistulas in the Fundament and elsewhere."

And there are many others recommended with various degrees of confidence.

In the great encyclopædic treasury of pathology and therapeutics compiled by Theophilus Bonetus, "*Medicina Septentrionalis Collatitia*" (Genevæ, 1684), we find the then current pathological notions of the Kings-Evil, as well as all recorded methods of cure. I will give some extracts from the English Translation, London, 1684:—

"Because there is a great likeness between the Kings-Evil and hardned glands (for they are alike both in place and matter), therefore we must do our endeavour to distinguish the one from the other. They differ first, because the matter of the Glands is more subtil and thin, of the Kings-Evil more gross and viscid, and more contumacious, and hence it is, that whenever a thin and subtil matter is incrassated, of Glands they become the Kings-Evil. Which is Galen's meaning, 1 *de loc. aff.* 3, when he says, that Glands sometimes turn into the Kings-Evil. Secondly, because indurated Glands are more separable from the adjoining Flesh, so that by the touch you may easily know it from the Glands: But the King's Evil is so propagated into

the adjoining Flesh, that it is a very hard thing to distinguish it. 3, Because the Kings-Evil has a Coat, but the Glands are always without one. Rogerius the Surgeon advises to take Ivy Leaves, and Citron, and pound them together, and lay them to the Swelling: and if the Swelling fall in 3 dayes' time, he says it is a sign they are Glands, and not the Kings-Evil; but if they grow worse with the application, so as to be red and ake, it is a sign they are not Glands but the Kings-Evil. . . ."

With regard to treatment we are told (under the same heading) how Mercurialis informs his readers that: "as soon as I observe Swellings arise in the Necks of Children, I find no more present remedy than to exulcerate the skin of the head, for this is the most proper diversion and evacuation. But we must have a care not to draw Blisters in Children's Heads with Cantharides. . . . But it is better to do it with Mustard, Nettles, Hony-suckle; yet with great moderation and prudence."

"Galen ad Glauconem . . . tells him that he gave astringent Medicines for the Kings-Evil. . . . In Rhases *lib. de Apostem* it is found that Plantain is very good in the Cure of the Kings-Evil."

"Rondeletius affirms that he has cured several of the King's-Evil beginning, by laying Cypress nuts upon the part." In this mode of treatment he confesses that he was merely carrying out the precept of his master Dioscorides.

Felix Platerus is the authority for the following:— "As we find that Narcoticks outwardly applied have a great dissolving faculty, so also, if applied in the Kings-Evil, they will do much: As leaves of Mandrake, Henbane, Poppy, bruised, or roasted a little under Coals or boiled or used any other way by themselves. Also Mandrake root, or powder added thereto, &c, The rubbing also of the Scroffles till they grow red, does also conduce something to the discussion of them; And if it be used before the application of Topicks, it better disposes them to receive their virtue."

"By a potential Cautey, which making an eschar in the Skin without pain opens the Scroffles, I have often got them out; or I have laid them bare, that they might be better suppured by applying Medicines. But it is dangerous to attempt this by actual Cauteries, seeing an Inflammation might easily follow. Yet in any ignoble place they might very well be opened in this manner."

The following remarkably successful form of anti-scorfulous treatment has been transmitted to posterity by Scultetus, of "*Armamentarium*" celebrity:—"A certain woman had the scroffles all over her Neck, and she was cured in a Months time. A powder of equal parts of Sugar, Ginger, and Turpeth was given her, which purges Phlegm particularly from the remote parts. After ceratum oxaleum was applied, they were softened with oyl of Lizards. Take green Lizards as many as you will, boyl them in common oyl till they be burnt, and the oyl turn black: let the colature be put in a Glass and set in the Sun till the dreggs subside, the oyl grow clear, and it be of a brown colour. Then I gave every Morning for 30 dayes of the Electuary, which H. Saxonia and J. Pravotius reckoned as a most sure secret; take some common or green Lizards, cut off their Heads and tails and take out the Guts, infuse them in strong white Wine Vinegar 40 dayes by themselves; then dry them and steep them in other Vinegar, and dry them again either in the shade or Sun, and reduce them to powder: which, being done, with one ounce of the powder mix 4 ounces of Honey. The Dose for Children is 2 drachms, for grown Persons. half an ounce, six drachms, or an ounce at most for 30 or 40 dayes."

The practice of Galen and of Severinus shows that the modern surgical method of wholesale extirpation of scrofulous glands is not so recent a mode of dealing with them as some latter-day operators would seem to have persuaded themselves. "We forbear not to cut out Scroffles, though they be crude and hard Tumours, but then they must be moveable, and not fastened to the flesh, and we may

draw them out with our Fingers, as we do steatomata and such things, having cut them from the skin and severed them round, with a knife broad and sharp-pointed and crooked backwards, according to Galen 14 m.m., cap. 11. I have tried this Chirurgical way of Cure with success in hundreds."

Bonetus closes his article on the subject with the following interesting list of

"MEDICINES ESPECIALLY MADE USE OF BY EMINENT PHYSICIANS.

"1. Drink every day out of a man's skull, and the King's Evil will then vanish. The Mushroom that grows on a Birch-tree, put in Wine and drunk, has a singular Virtue in gradually curing and wasting the Kings-Evil." (Agricola.)

"2. It has been observed that Scroffles and other Tumors fall, if the Part affected be rubbed with a dead man's hand, for so the swellings gradually vanish as the dead Body rots by degrees. (Bartholinus.)

"3. Root of Vervain hung about the Neck of one that has the Kings Evil gives wonderful and unexpected relief. They say Silver-Knapweed is marvellous good; also red Poppy steeped in Wine, and bruised, and the Mucilage applied to the Swelling, is a Medicine that does good by tempering, and has those Virtues which we require in Medicine for the Kings-Evil, over drying things being excluded. (Baricellus.)

"4. Three Toads boyled in Oyl Olive in a glazed Earthen Vessel, make an excellent Oyl, for the Kings-Evil; but the fumes of them, while the Oyl is in making are dangerous. Therefore, keep that vessel close, and have a care. First they apply Arsenick to the Scroffles, and blister them, then corrode the Part with sublimate, and use the said Oyl, which will be yet better, if you infuse the salt of Toads in it. (Borellus.)

"5. This Potion has been often tried, which not only takes away the Kings-Evil, but all Mucosities of the Throat; take of Broom-flower Water 3 ounces, drink it warm with Sugar in the Morning. The Powder of Brown-flowers does the same mixt with Honey of Roses. (Sebast. Cortilio.)

"6. The lesser Celandine has 4 or 5 grains like Wheat growing to its root, which are used to draw out the Scroffles with great success.

"7. Their cure depends upon the Meazles of Hogs, which may be calined and sprinkled on them, and Oyntments may be made of them, which are very good for the Cure of these Swellings and these Unguents may be fortified with distilled Oyl of Hogs-Lard, or distilled Oyl of Hogs-Meazles, which is a specifick against the Kings-Evil. (Joh. Pet. Faber.)

"8. If the Kings-Evil must be taken away by causticks, there is no better Medicineto take them away, than sublimated Arsenick; but you must have a care, that the Parts near the Swellings do not Putrefie or Inflamm (Guil. Fabricius.)

"9. An excellent Electuary to take away the Kings-Evil is thus made: Take of the Bones of a Hen, the flesh whereof has been boyled off, dry them, and powder them. Take of this Powder and Seed of Sesamum each alike, as much as you will, with Honey make an Electuary. Take a drachm at a time Morning and Evening all the decrease of the Moon till the new, and then repeat it the following decrease of the Moon. (Rod. a Fonseca.)

"10. The use of the Powder of Sponge will cause it to decrease, if you drink as much as you can take upon a knife's point, in Cinnamon-water. The sponge must not be burnt, for then its Seminal Virtue is destroyed. (Grembs.)

"11. This is admirable for the Kings-Evil, Throat rupture, Parotides, and all hardness. Take the leaves of Cypress, neither the tenderest nor the hardest, reduce them to powder, Sprinkle them with strong Wine, and turn them, till the Body of them turn to dreggs. Lay it upon the Scroffles or Rupture and the third day take the Medicine, you will find the Place contracted, which must be squeezed out with the Fingers. Let this Medicine be repeated, and on the Seventh or Ninth day at farthest, the Kings-Evil will be gone to a Miracle. (Hollerius.)

"12. Take of Root of Fern, Spleenwort, Dwarf-elder each 3 ounces, cut them and boyl them in the best Wine, then pour away the Wine, bruise the Roots, and add of live Sulphur 1 ounce, ashes of Cockle-shells, 2 drachms. With equal parts of Honey and Vinegar reduce them into the Form of a Cataplasma, lay it upon the Scroffles, it consumes them wonderfully. (Fr. Joel.)

"13. There is scarce any Plant of so great Power in softning and discussing Swellings in the Kings-Evil, &c., as the bulb of Cornflag and Hog's-Lard outwardly applied. (Laurembergius.)

"14. It has been found by experience, that burnt Allum powdered, if half a drachm of it have been given in Wine alone, or mixt with other discutient and drying Powders has done much good in this Case. (Platerus.)

"15. Root of Figwort eaten for 10 dayes every Morning fasting cures the Kings-Evil."

(To be continued.)

NURSES OF THE LATEST FASHION. A.D. 1899.

PROFESSIONAL EXPERIENCES IN SHORT STORIES.

By FREDERICK JAMES GANT, F.R.C.S.,

Consulting Surgeon to the Royal Free Hospital.

MY attention has been lately drawn, very powerfully, to the conduct of nurses engaged in private nursing. This limitation at once excludes my retrospect of nursing in hospital practice during a period of forty-five years (1899).

Accumulating personal knowledge, reinforced by the experiences of many authoritative members of my own profession assures me that the character, as disclosed by conduct (no less than the technical qualifications) of not a few private nurses, is such as defames the general body of which they are members. Mostly, if not only, among the "untrained" and "uncertificated" class of women, who style themselves nurses or nurse-attendants, misconduct—in various forms, prevails; desecrating the fair fame of the rightful Order of Women, and by demoralising many a home, begets lasting misery in personal and family life. I am not without hope, that the portraiture presented in "Nurses of the Latest Fashion" will fulfil a right good purpose, by tending to eradicate some nurse-forms of wickedness and vice—who as mildewed ears of nurse-womanhood are thus blighting their wholesome sisters, and blasting their just claims to the confidence reposed in their beneficent vocation. In telling the "stories" based on some of my professional experiences, the illustrations given of these false nurses, and of the other *dramatis personee*, with the incidents narrated—do not pertain to individuals—they are alike wholly impersonal characters, and yet realistic.

It behoves all women, as nurses, to bear ever in mind that they are members of a body; and that each should hold herself responsible for a professional character which she is thus bound to maintain or to retrieve.

A PLEA FOR STATE REGISTRATION OF NURSES.

The animated photographs and experiences to which I invite attention in the following series, chiefly in the form of stories, concern not only nurses, but the public also. Few people there are who pass through life without knowing something of nurses, in their times of needful help and care; and many remember these "ministering angels" with the most grateful appreciation of the devoted attention, skill, and kindness, with which they fulfil their duties in the spirit of a sacred calling.

But the qualifications and the personal characters of nurses differ widely. Nurses "trained" in hospitals of different grades, and for a *variable period*, and nurses untrained, "certificated" and uncertificated, are alike competing in any number to get "private practice," as distinguished from hospital work; and as their relative merits and demerits, are alike covered by the title "nurse" or "nurse-attendant"; all share *equally* the

claim for admission into the mansions, the houses, the homes of the class of society who can afford to remunerate them, according either to their perhaps equal demands for their services, or the scale of charges provided by various competing institutions of nurses. All these women dress very much alike—as roses, dipped in the morning dew of blessing, trust, and hope—angelic to the weary sufferer, and sorrowful relatives and friends.

Of course the untrained eye of wife and mother, of husband and father, cannot possibly see at first sight, nor perhaps discover by after observation, more than the outward appearance and manner, and conversation, of the new friend in need, a friend indeed. A charming attire—neat, not gaudy—decidedly religious-looking, surmounted by a pretty capped-faced of healthy colour, and cheerful expression, or sallow and work-worn, perhaps saddened; hands scrupulously clean; a quiet, subdued, sympathetic manner; a mellow whispering voice, like the tones of an æolian harp, fanned by zephyr winds in Paradise. The note-words breathe God's humanity, with consolation and cheery hope.

Even the family doctor with his practised eye and ear, may see and hear—no more; glad, beyond measure, that there is such an outward form of perfect womanhood to represent his attendance in the morning, when oh, God, would it were evening, and at nightfall, when oh, God, would it were morning; and having full confidence and trust that amid his toilsome rounds of day and night professional duty, he can conscientiously feel relieved of his cares and responsibilities by the heaven-sent one; never, when "pain and anguish wring the brow," or in convalescent hours, will his patient know an evil spirit, thou!

If I were asked what, in my experience are the most prevalent vices among so-called nurses up to date, and which most urgently need to be eradicated, I, with friendly frankness, would say (1) untruthfulness and slandering; (2) pilfering; (3) sensuality and intemperance; (4) cruelty in their duty; (5) idleness, or perfunctory work, without any heart in it; the ruling principle of the nursing vocation (itself a sacred calling) being to get the highest wages for the least amount of work done, otherwise than in novel, magazine, and newspaper reading, letter-writing, and making articles of dress for themselves or their relatives; with increasing hours off duty; for shopping, calling on friends, corner of street-appointments, &c., and holidays at pleasure. Matrons there are whose disqualifications of character I am not portraying, who may be disfigured by some such personal defects—e.g. (4), cruelty in their "duty" to patients in homes and refuges.

But, if with many "steadfast and true" in, and to, their vocation; there may be also many, some, or few, commingled with their sisters, who cannot be distinguished by the public, or the professional eye; an authentic general Register of names, with *uniform* qualifications, and approved character, should be the credential for security alike for nurses and the public.

In the second Charter for the Incorporation of the Royal British Nurses Association, of which H.R.H. Princess Christian, is President, Her Majesty's Privy Council permitted only the term, List of Nurses, not a Legal Register.

But *State* registration of nurses would regulate more than the obvious inequalities of the certificate system, with regard to the technical qualifications and personal character of that order of nurses at present authorised by various *private* Nursing Institutions, or as hospital private staff nurses, each of which have rival interests, and are of unequal competency, in their *competitive* certification.

The full training—perhaps the *over-training*—of certificated nurses has carried with it a scale of remuneration for *their* services—in private cases, which has opened the doors of the vast majority of householders, and the bed-rooms of a population of lodgers in sickness, to the ministrations of another order of nursing women, instead of the certificated.

The service of a certificated nurse, at £2 2s. per week, amounting in chronic (lasting) cases to 104 guineas per annum, exclusive of good board (perhaps separate

meals) and bedroom to watch, or two such nurses for day and night service—is a luxury quite beyond the reach of most well-to-do householders and lodgers, constituting the professional and business classes—the bulk of society.

The fact that (some) private nurses, who are attached to institutions—worked perhaps upon the "co-operative" principle—do not *themselves* receive the whole of the remuneration for their services, does not lessen the burden on the public who engage them. Thus, each such Institutional nurse, say, co-operative, "receives at least £50 a year, and considerably more if she is fortunate in making herself liked, or if higher fees can be obtained" by the business-nursing speculation; the other half share of her wages being retained for the *maintenance* of the Institution, in consideration of providing her a home, in the intervals of her cases, or in the event of illness. The public still pay for the certificated nurse, £2 2s. per week, as including *her* maintenance, when out of work, or temporarily disabled.

In these circumstances, touching the financial relation of nurses to the public needs, an uncertificated nurse, of whom there are at least, hundreds as "nurse-attendants," with, or without adequate, or any practical knowledge, and with, or without, any guarantee as to her known personal character and antecedents, hears, or reads by advertisement, that *she* is "wanted"; and forthwith she undertakes the case, whatever its nature, at £2 2s. (not per week, but) per month, at the rate of £25 a year.

Surely this latter order of women—at present a social necessity—should for the security of the public, be included (in a separate list) on the same legal register; and all such nursing women, thus enrolled, should hold a special certificate—expressly stating that they are incompletely trained or untrained, and with special regard to their personal character, the latter being a guarantee even more requisite than with regard to nurses whose personal qualities have been tried and proven in the course of hospital training under supervision, to practice in private cases from an institution or hospital, or on their own account.

The author in presenting these papers on "Nurses of the Latest Fashion"—whether by the unauthorised assumption of the nursing vocation, or who are imperfectly certificated—would, therefore, humbly urge his plea for "State Registration" of the *whole* body of nurses and nurse-attendants in one common legal register; just as—and for analogous reasons—all recognised members of the medical profession are enrolled on a legal register of professional qualifications.

I.—SATAN IN PETTICOATS.

In the stories I am about to relate wherein some nurses will figure as the heroines, and of whom I would present animated photographs, the first of these in its completeness, is probably an exceptional species, under cover of a nurse's dress, &c.

Nurse Lucretia is *partly* the money-seeking, fortune-hunting woman, but she gains admission to the house of sickness and death simply to play a game best suited to carry out certain diabolical purposes. There are other ladies in the world of fashion and beauty who are fortune-hunting of men, who themselves may be no less engaged in the same vocation. Some such women may be known to every reader of this journal, who has met them in the World's Mart. They are to be seen in Society's salons, as living specimens of their craft, without studying Thackeray's "Newcomes," in the person of Ethel Newcome, the heartless *coquet* who would have sold herself body and soul, for wealth (and rank); more beautiful she, in her tears of remorse and loving care of her brutal brother's children, than ever she looked in the flushed excitement of the ball-room, with Lords Kew and Farintosh, with whom, and other game, she would equally divide her fickle favours. There are yet other E. N.'s, unknown to the Hogarth-Novelist; nurses, whose representative portraiture, an humbler artist would sketch with a pen dipped in the blood of his thought.

Nurse Lucretia is of Borgian blood; cold, calculating cruel. She would vary the depravities of an incestuous,

nature; she would seduce husband, or son, even in the room adjoining the departing spirit of wife and mother; or she administers slow poison preferably by (accidental) over doses of some potent medicine; selling herself, or with a redoubled display of nursing care; in either way to gratify the only love she ever feels—her passionate love of money. With an elderly gentleman patient, nurse-poisoner smooths the pillow, and caresses the sufferer for a *post obit* bond, given to her as a tribute of gratitude for her affectionate and unremitting devotion to him; a free gift, which shall not appear in his Will, lest perhaps £10,000 or £20,000 should be disputed by surviving claimants.

Bosh! there are no such women-nurses. Yes, incredulous reader, and some such disguised "uncertificated" nurse may get into your home any day—if not Lucretia, one of her blood-sisters, there to exercise her hellish trade upon whomsoever may best answer her fell purpose. She is the devil in petticoats. Here is one such "nurse attendant," an illustration of the species, as developed up to date. She would have quite misled anyone with less knowledge of human nature and (feminine) character than a practised observer, who, while he can fully appreciate the true and the beautiful in woman, is also a judge of blacking.

This Nurse Lucretia, when out of place—a frequent circumstance in her yet young life, daily consults the newspapers of fashionable or church connection, as best representing the wealthy and titled, or the saintly classes of that society among whom she looks for the most profitable find.

In reply to an advertisement, otherwise perhaps most unsuitable for a trained nurse, she would do herself the pleasure and the honour of calling, feeling sure that her special knowledge in accordance with the advertisement, besides considerable general nursing experience, would enable her to give entire satisfaction in the faithful performance of her duties, similar, indeed, to those in the situation she had just left. Not a word about character or reference, or both may be offered.

Nurse Lucretia calls within a few hours, and sees the patient; if alone, so much the better. She is alertly in advance of other nurse applicants, some of whom arrive during her brief visit, and are waiting in the hall their turn for being engaged, as she passes them to the street door with a jubilant expression in her face. For Nurse Lucretia has made such a personally favourable impression, that none others applying have a chance. No character or reference was needed from Lady U—, whose service she was leaving.

A mourning brooch which Lucretia wore, was—she said—the gift of a family in grateful memory of her attendance upon one, whose loss to them was irreparable. Time seemed only to mock their grief; and nurse often accompanied the disconsolate widower and his motherless children to the cemetery, bearing floral tributes to the power of death which had so mysteriously taken their loved one from them. But ah, she had walked with God "on earth" and "He took her," at last away. The value of Lucretia's mourning brooch was enhanced by the additional gift of £100 two year's full wages.

Lucretia returns in the evening to commence her attendance on an elderly lady, who although stricken with one-sided paralysis, is singularly acute in money matters; her husband, an old man, with much of the heart of youth, is a sort of scientific religious, and although possessing mature professional experience in the art of healing, is not singularly gifted as a financier.

Lucretia is a spare, lithe, active little woman, of graceful figure, with a face which might have been pretty, but sadly indicative of a past, within the short life of thirty years; the features are hardly to be noticed; for the flushing cheeks, playful little mouth, slightly upturned nose, and open forehead surmounted by a frizz of auburn hair, seem lost to sight, in your rivetted view of gentle hazel eyes, while the ear listens to a silvery voice as of an angel in mercy sent.

"She is come, she is come," sang in chorus the second nurse-attendant with the servants, as the fascinating little woman tripped or flitted with Ariel's wings into the bed-chamber, announcing her arrival to "the dear

old lady." Yes: and as Ariel might have said to 'the husband—"Hell is empty, and all the devils are here."

But for a moment, a little pecuniary difficulty occurred, ere Lucretia could be installed to commence the duties of her beneficent nursing vocation. The cabman had carried her box on his stomach and safely deposited the precious burden, full of dainty nurse apparel, &c., in the hall. "That ere young lady has not paid my fare." This just cause and impediment being made known to the fare-forgetting fair one, a silvery-bell voice replied from the drawing-room landing, 'Oh, just give the man one shilling, that is more than his due.' Nurse Lucretia had come direct from Lady U—, and in the hurry of packing her box, she had left her purse in her bed-room, under the pillow. Lady U— would doubtless forward it (the first-named valuable article) to her by book-post. The confiding and generous second nurse-attendant at once discharged the lady-nurse's liability by paying the necessary coin. On seeing this friend in need, however, a trace of momentary confusion passed over her self-possessed countenance; those liquid eyes which ever met yours were downcast, and the playful little mouth, around which ever danced a smile, refused its wonted performance to its owner. Then the bell tinkled, "I was not aware that there is a second nurse-attendant in this case; for my heart is easily won," glancing at the old lady, "and as my work is done in God's service, I like to have the patient all to myself. At least if a helper is needed, as seemingly in this case of paralysis for lifting the poor dear sufferer, I must have the sole personal charge of her, and especially in that spiritual time during the solemn hours of darkness." The uplifted eyes of the helpless sufferer bespoke a gladsome response to the sympathetic look and touch of the heavenly visitor; and the simple, honest, and faithful No. 2 bowed her assent to this arrangement.

But it is necessary to mention the terms of Lucretia's engagement. The paralysed old lady had engaged this handmaid of the Lord; making terms with her quite unknown to the old husband, and probably for this purpose she had been so desirous of seeing the patient alone. Happily a warning voice had whispered, "take her on trial for a month, but terminable by either party at that period."

The wages, even for an angel, could only be in their circumstances, with heavy additional expenses, £25 per annum, and everything found. Lucretia looked for a moment, disappointed, "perplexed but not in despair, cast down, yet not forsaken," as she would have expressed her position; "£25, &c., a year," said she. "Well, she had never received less than £50, or in that proportion of remuneration, for her services rarely lasted so long a period as one year; but in the pecuniary circumstances mentioned, £25, or at that rate of weekly payment, she would accept these terms; in consideration also of the helpless invalid to whom she already felt attached; anxious, moreover, to meet her offer in a spirit of Christian love; she willingly and gladly thus concluded the agreement. And she felt sure that she was sent by Him, &c., &c."

This agreement was, as in other similar cases, entirely verbal; but no one had heard the terms; even the second nurse-attendant being out of the room. The patient, reduced by suffering and age, as well as having had a paralytic attack, and the handmaid of the Lord, were the only parties to the contract.

The old lady listened patiently, but with some nervous restlessness to nurse's previous experiences, painful yet delightful, as she told them with her bewitching smile: nursing in her skilful hands seemed to be quite a fine art, and life-giving. She told the patient of "antiseptics" (antiseptics), for so nurse's little mouth lisped the word; "the Röntgen rays, dear madam, for examining you internally—say your heart," as Lucretia placed her marble hand upon that treacherous organ in her own bosom. "Then there's the 'funnygraph' (phonograph) into which if you speak, your every word is registered, and can be re-spoken years afterwards, even as they are recorded in heaven." Pausing; "but I alarm you; yet why should not all we say—as well as do—be registered *there*," with up-pointing finger; "who, say

nothing but what is *true*, honest, pure, lovely, and of good report."

Miss Lucretia B—, bearing her full name and prefix by box label—quite captivated the simple, truthful-minded dear old lady-patient (for so she is); indeed, some such jargon of religion with scientific-nursing accomplishments had at once won her heart, and somewhat enfeebled understanding, on the occasion of nurse's first visit.

By similar tactics, it is more than probable that other nurses, who by no means rival Lucretia in the special features of her character, are prone to display their vast experiences and technical knowledge, and may thus gain more influence over a patient—albeit for no evil purpose, than the most able doctor. We shall, in the course of these stories, produce some further illustrations of spurious nursing-methods for thus exalting the lamentably ignorant, or the unprincipled women, who practice these devices.

Thus captured, in her husband's absence from the bed-chamber, the credulous sufferer, after her first interview with nurse, had sent a message to the old gentleman below, that "she had seen such a clever, and good woman, with such delightful manner, and engaging conversation; one also who would read her favourite prayer—"Thy Kingdom come," morning and evening; in these happy circumstances she had ordered Robinson, the maid, not to admit any more applicants of whatever kind." With this message warm in his breast, the loving old husband seemed to be content, and thus relieved of his anxious solicitude for her comfort, a devoted wife's heart-to-heart union of forty years married life would allay his own incessant suffering of several years duration and breathe peace to him. Was this twofold blessing—one for each of the old couple—realised?

The old lady upstairs, of whose soul and body the ministering angel had now gained entire possession, was beautifully passive in the hands of her nurse attendant; grateful, as her nature is wont to be for the smallest favour, she at once "fell in love," as a man would say, with Lucretia; in the long days and yet longer nights of suffering or helplessness, almost bed-ridden for a wearisome period, this faithful watcher learnt, with the adroitness of the most skilful legal cross-examiner, all about her patient's family connections, her property—"free from the debts and control of any husband"; and in return for all such confiding information, Nurse Lucretia became "the guide, philosopher, and friend" of the old wife, without at present extending her favours to the old husband.

(To be continued.)

Clinical Records.

CANCER HOSPITAL.

Case of Excision of the Rectum and Vagina for Cancer.

Under the care of CHARLES RYALL, F.R.C.S.,
Surgeon to the Cancer Hospital, Brompton; Surgeon to Out-Patients, London Lock Hospital; Surgeon to Out-Patients, Gordon Hospital for Diseases of the Rectum.

E. W., *et. 51*, married, was admitted into the Cancer Hospital on April 4th, 1899, and gave the following history. For the last two months she had had pain during defæcation and continuing for some time after the act. She had also suffered from constipation and occasionally from a discharge of blood and mucus. There had been no marked loss of flesh. She had had no previous severe illness and had always enjoyed good health. On examination the growth was found occupying the lower three inches of the rectum, involving the whole circumference of the bowel, and it was most extensive anteriorly where the anus and the lower two inches of the posterior vaginal wall were invaded by the disease. The affected part was movable, and there was no evidence of metastatic deposits, so the case was considered a fit one for operation.

Operation, April 8th, 1899.—The patient being under the influence of ether, she was placed on her left

side in the semiprone position, with the thigh well flexed on the abdomen. A median incision was made from the middle of the sacrum to the anus, and the muscular and ligamentary structures and middle sacral vessels were freed from the lower end of the sacrum and the coccyx. The lower two pieces of the sacrum and the coccyx were then removed by the bone forceps and the exposed part of the rectum was separated from the surrounding soft parts. The peritoneum of Douglas' pouch was incised on both sides of the bowel and by dividing a little of the mesorectum sufficient of the rectum could be freed to meet the requirements of the case. The bowel was now divided well above the disease and the upper divided end was secured to the skin below the remaining portion of the sacrum, or, in other words, to the upper angle of the wound. The rest of the peritoneum of Douglas' pouch was separated from the bowel, and then the peritoneal cavity was closed by suturing this peritoneum to the anterior surface of the upper remaining part of the rectum. The lower portion of bowel was now rapidly freed from the upper and unaffected part of the vagina, and the lower diseased portion with the diseased part of the rectum and anus was removed. The orifice of the remaining part of the rectum was now secured in the upper angle of the wound as described, in order to form the future artificial anus.

The rest of the wound was then closed by deep and superficial sutures which thus formed an artificial perineum and necessarily narrowed the vaginal orifice. The bowels were kept confined for 48 hours, after which an aperient was administered, but every care was taken to prevent faecal contamination of the wound. The patient made an uninterrupted recovery, and the wound healed by primary union, and she was discharged from hospital four weeks after operation. She is now well and able to carry out her household duties and exercises control over her sacral anus by means of a rubber plug and pad

Transactions of Societies.

BRITISH GYNÆCOLOGICAL SOCIETY.

MEETING HELD THURSDAY, JULY 13TH, 1899.

Dr. MACNAUGHTON-JONES, President, in the chair.

SPECIMENS.

MR. CHARLES RYALL showed a vagina and rectum removed for malignant disease, notes of which will be found in another column under the heading "Clinical Records."

In the discussion that followed, Dr. HEYWOOD SMITH asked how far down the posterior vaginal wall the growth extended? Was Mr. Ryall able to leave a part of the vagina?

Dr. C. H. F. ROUTH asked whether the patient had now complete control over the rectum?

Mr. BOWREMAN JESSETT congratulated Mr. Ryall on the success of the case. The only question was whether the same result might have been obtained without removing the lower part of the sacrum. If the finger could be got above the disease the old operation would sometimes answer, and the sphincter action could be retained; but in many cases the disease could not be got completely away without a Kraske's operation. In one case he had the pleasure of assisting Mr. Ryall to remove the upper part of the rectum, and the lower part of the sigmoid; the way in which Mr. Ryall did the operation was deserving of the highest praise; he connected the two parts of the gut, and the patient was now able to get about and pass the motions in the ordinary way.

Mr. RYALL, in reply, said that the lower part of the vagina was affected, so that this portion had to be removed; the effect was that the anus was higher up than usual, and the patient had not sphincter control. By wearing a plug, she was able to get about all right. In this case one could not have done the perineal operation, because the peritoneum would have had to be opened in any case

Dr. HERBERT SNOW exhibited a uterus removed for multiple myomata from a patient, æt. 47. The symptoms were of five years' duration. The patient was worn out by repeated attacks of hæmorrhage, latterly almost continuous, with much pain. The uterine body was completely buried in myomatous masses. Two of these had not only contracted membranous adhesion to the bladder-walls, but had become incorporated with them in such a manner as to form two *culs-de-sac*, large enough to admit two fingers. Dr. Snow had not met with this condition before, and would be glad to learn if any other member of the Society had seen it. He regarded the pouches as peritoneal diverticula which had become segregated; like the portions of the funicular process which not seldom remained patent and isolated, upon the spermatic cord, giving trouble in later life. It had been suggested to him that they were lymph-spaces, but he thought they were too large. The nodular masses impinged on the bladder in such a manner as to necessitate careful dissection, and to make it impossible to tie the uterine arteries before division. In thus separating the tumour one suddenly entered a rather large cavity, lined by a mucous-looking membrane. Although the latter had not the rugose appearance of the bladder, it was necessary to pass a bougie before one could feel sure an accident had not taken place. This occurred twice. The Trendelenburg posture was used, and the operation was that modification of Dr. Heywood Smith's which Dr. Snow had lately brought under the notice of the Society. It consisted in dissecting off and suturing together thin flaps of uterine tissue over the residual cervix. Thus all risk of wounding the ureters was obviated, and firmer union was gained than by merely sewing flaps of peritoneum easily torn at the time or subsequently ruptured in attacks of vomiting. The patient made a most favourable recovery.

Dr. SEPTIMUS SUNDERLAND showed the following specimens:—

CASE I.—*Subserous Fibroid removed by Abdominal Myomectomy*.—The patient, a nullipara, æt. 39, was sent to Dr. Sunderland by Dr. Arthur Thomas, of Wands-worth Common, complaining of constant abdominal pain and the passage of very thick and clouded urine. She had always suffered from dysmenorrhœa, and had noticed enlargement of the abdomen for several years. Relief from suffering, by any means, was begged for by the patient and her husband; and after a month's trial by rest and drugs, with no result, they wished for operation. The tumour, nodular in places, occupied the lower part of the abdomen fitting very closely to the iliac fossæ and extending nearly to the umbilicus, and could be felt per vaginam pressing on the bladder. The uterus felt retroverted and rather bulky. A sub-peritoneal fibroid was diagnosed and, on operation, the tumour was found growing from the fundus uteri by a broad rounded pedicle (practically continuous with the large fundus uteri) which, according to the incised area seen on the tumour, would measure 6 ins. in circumference, 2½ ins. broad, and 2½ ins. from before backwards. There was a firm and broad adhesion to the bladder on the left side which required transfixing and tying, and a firm adhesion to the intestine at the upper part on the right which was also tied. The patient made a good recovery, and the bladder symptoms and pain disappeared.

CASE II.—*Large Hydronephrosis, simulating Ovarian Cyst, removed by Laparotomy*.—The patient, a slightly-built, thin girl, æt. 14, was sent to Dr. Sunderland by Dr. Aubrey with an abdominal tumour, diagnosed as an ovarian cyst. The patient and her mother had noticed the abdomen increasing in size during the previous thirteen months. Until the week before she came to him there had been no pain, and she then complained of a feeling of discomfort more than actual pain. The whole of the lower part of the abdomen from an inch above the umbilicus, was dull on percussion excepting a small space in the right flank. The tumour evidently contained encysted fluid, and was again diagnosed as ovarian cyst, but on opening the abdomen in the middle line the tumour was found to be covered by peritoneum. Dr. Sunderland removed the tumour by enucleation, and ligaturing a pedicle containing the

vessels and situated several inches distant from the ureter, which was tied separately. There was no hæmorrhage, although the enucleation was not easy in some parts. The fluid was removed by tapping, in the course of the operation, and consisted of about seven pints of urine. The flattened kidney substance could be seen at the back part of the specimen, which was much shrunken on account of its being badly preserved. The patient recovered rapidly after the operation.

Mr. J. FURNEAUX JORDAN said that there was sometimes a difficulty in diagnosing between renal and ovarian cysts. He had reported a case before the Society. The abdomen was larger than a full-time pregnancy; the cyst had grown in a few months without pain, and was situated a little more to one side than the other. Examination of the urine gave no result. He opened the abdomen, thinking it was an ovarian cyst; in the cyst were found 33 calculi. He did not examine the other kidney at the time, but the patient died in forty-eight hours of anuria. He then found that the other kidney was affected and contained seven large calculi. It was remarkable that the patient had had no pain at all.

Mr. BOWREMAN JESSETT remarked that some few years ago a patient came to him who was passing blood and pus, and he diagnosed a renal calculus. She would not be operated upon; the pus disappeared, and she got well. After two years she returned with total suppression. She then had a large tumour on the opposite side; he operated, and she got quite well. Two years later she again returned with a large tumour on the same side, and again he took away several calculi. After two years more he operated for the third time, and the patient died. At the autopsy both kidneys were found atrophied, with hardly any kidney-substance. It was remarkable that the patient had been able to live so long.

Dr. HEYWOOD SMITH said that sixteen years ago a young woman came to him with a large tumour reaching above the umbilicus; she had seen Mr. Thornton, who advised aspiration. This was done in the afternoon, and she died two hours later. At the post-mortem both kidneys were found much distended, and within each was found a large oxalic acid calculus. He asked Dr. Sunderland what method he had adopted for the removal of the myoma.

Dr. ARTHUR GILES commented on the difficulty of diagnosis in these cases. He had assisted one of his colleagues at a celiotomy undertaken for what was thought to be an ovarian cyst; the tumour occupied the middle line of the abdomen, which it filled, and reached down to the pelvis. There were no symptoms or signs pointing to the kidney as the seat of the tumour. On opening the abdomen the cyst was found to be retro-peritoneal, and its true nature was then, of course, evident. The peritoneum was divided and the renal cyst dissected out and removed. The patient made a good recovery.

The PRESIDENT said that he had twice seen a pyonephrosis mistaken for an ovarian tumour. He had also seen a case which he diagnosed as renal; on tapping, he drew off two pints of pus; the patient got well. These cases showed very well the disappearance of the kidney-substance and its conversion into a cyst. It was often difficult not only to diagnose between a renal and ovarian cyst, but also to say which kidney was affected. This was a point in favour of dealing with these cases by the abdominal route.

Dr. F. A. PURCELL remarked that other tumours besides renal ones could be mistaken for ovarian cysts. He had a case in which a patient who was pregnant had a large cystic swelling; the abdomen was opened and the cyst tapped, when it turned out to be a distended bladder. The nurses had said that the bladder had been emptied, the urine being drawn off with the catheter. The wound in the bladder was sewn up, and the patient recovered.

Dr. R. HODGSON pointed out a diagnostic sign between the two kinds of cyst; with hydronephrosis there was usually dulness in the flank, whilst with ovarian tumours the flank was usually resonant.

Dr. SEPTIMUS SUNDERLAND, in reply, said that he had not passed a sound down the cut end of the ureter toward

the bladder as suggested by Mr. Jessett, to determine if a stone were present in the ureter and he wished he had done so. He had found the actual kidney substance very low down in the abdomen, and he thought possibly the kidney had originally been a congenital "floating" kidney. On the other hand, the kidney substance might have been displaced downwards by the pressure of the urine as it collected. To Dr. Heywood Smith and the President, he said the urine was examined before operation and contained no pus—it was quite clear and normal. No, he had not used Langenbeck's incision—he had thought the tumour was ovarian, and opened the abdomen in the linea alba, and even then it was not easy to decide whether the cyst were renal or mesenteric. He had on two occasions seen the abdomen opened by operators when ovarian tumours had been diagnosed, and when one case proved to be a pyonephrosis, and the other a hydatid of the kidney—both on the left side, but in neither case had the tumour been as large and exactly simulating an ovarian cyst as in this instance. He had also heard and read of other cases. He was interested to hear from Mr. Furneaux Jordan of a similar experience in his own practice, and he thanked Dr. Giles and Dr. Hodgson for their remarks as well as the other speakers.

In reply to Dr. Heywood Smith, Dr. SUNDERLAND, although at first contemplating supra-vaginal hysterectomy on account of the size of the pedicle, which was as big as the enlarged fundus uteri, had removed the tumour by a circular incision around and through the thick pedicle. He then removed a wedge-shaped piece of tissue from the base of the pedicle, arresting bleeding by four transfixion ligatures, and brought the edges of the stump together by silk sutures. Thus the uterus and ovaries were left to the advantage of the patient.

Some interesting cases were also shown by Dr. Keith, Mr. Jessett, and the President; and papers by Mr. Charles Ward, of Pietermaritzburg, and by Dr. Laphorn Smith, of Montreal, for all of which we hope to have space in our next.—ED.]

France.

[FROM OUR OWN CORRESPONDENT.]

PARIS, July 23rd, 1899.

RETRO-UTERINE HÆMATOCELE.

At the meeting of the Société de Chirurgie, M. Routier spoke on the treatment of retro-uterine hæmatocele, and said he was a partisan of opening the tumour through the posterior *cul-de-sac*. M. Chaput admitted that that mode of treatment was excellent, but sometimes the patients lost a great deal of blood. One of his patients operated at the Tenon Hospital succumbed in this way. After having incised the posterior *cul-de-sac* and evacuated the tumour, he plugged the wound with iodoform gauze; in the afternoon the patient developed all the signs of internal hæmorrhage and died before help arrived. Ever since he was careful to place only a simple plug and to wait events; if the hæmorrhage continued he performed laparotomy.

M. Lucas said that he would never willingly incise an hæmatocele per vaginam. Laparotomy was the operation indicated in such cases, as it permitted the inspection of all the points which might bleed. M. Pozzi never witnessed the slightest accident following the opening of the posterior *cul-de-sac*. He had seen more than once serious hæmorrhage occur, but he could always control it by hot injections and plugging. However, in extra-uterine pregnancy, laparotomy was indicated.

M. Regnier considered it was always very difficult to distinguish between extra-uterine pregnancy and hæmatocele. It was always where the hæmatocele was recent, that the danger of profuse hæmorrhage existed.

Consequently, it would be well to postpone interference, one way or the other, for three weeks after the first symptoms.

MENSTRUATION THROUGH THE EAR.

M. Lermoyez related how he attended for several years a young girl who menstruated for a very long time by the right ear. Every month, after general prodromic symptoms, such as lassitude, headache, a thin stream of blood flowed from the ear, although no lesion could be detected. The tympanum was intact, but the cutaneous vessels of the external auditory canal were much enlarged. At the end of three years menstruation followed the ordinary channel.

GASTRIC ORIGIN OF SKIN DISEASE.

M. Robin said that for a long time clinicians suspected that certain forms of dyspepsia played a rôle in the genesis of some skin diseases. Out of 422 dyspeptic patients studied by him, 129 presented acne, eczema, lichen, prurigo, urticaria, furunculosis, herpes, &c. On the other hand, he particularly studied the gastric secretion of several patients suffering from prurigo or simple eczema, but who did not present any dyspeptic symptoms, and he found that they suffered, nevertheless, from a form of dyspepsia due to lactic or butyric fermentation. Consequently, he was convinced that these fermentations acted on the skin through a trouble of nutrition (insufficiency of the general exchanges increase of demineralisation, &c.), or by elimination of lactic acid in the perspiration. The treatment should naturally be addressed to the special form of the dyspepsia. If the fermentation be due to the presence of lactic acid, the fluorides should be ordered, while sulphur, iodide of sulphur, or iodide of bismuth, were the best agents against the butyric acid form.

HÆMOSTATICS IN THREATENED ABORTION.

In hæmorrhage resulting from threatened abortion, the custom is, after providing the means destined to calm the uterine contractions—opium, rest, ice to the hypogastrium—to prescribe an hæmostatic agent which will not provoke tetanic contractions of the organ, such as *hydrastis canadensis*, *viburnum prunifolium*, or *hamamelis virginica*. According to Prof. Bossi, these agents prescribed alone are not always to be relied upon, on account of the difference of temperament so frequently witnessed in patients. Much disappointment would be obviated if these agents were prescribed together according to the following formula:—

Fluid ext. of <i>Hydrastis canadensis</i>	} 3 ij;
„ <i>Hamamelis virginica</i>	
„ <i>Viburnum prunifolium</i>	
Tincture of <i>Piscidia erythrina</i>	
Laudanum, xxx m.	

A teaspoonful of this mixture to be given every eight hours if necessary.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, July 22nd, 1899.

At the meeting of the Medical Association of Berlin on June 27th, 1899, Hr. von Leyden read a paper on

THE INNERVATION OF THE HEART.

He reviewed the subject in outline, historically noting important discoveries, such as that of the influence of the

vagus, the accelerating and depressor nerves, and the existence of the cardiac ganglia, all of which led to clearer views on the wonderful problem of how the heart continued to beat the whole life through. Apparently, those discoveries placed the theory as to the dependence of the heart's action on the cardiac nerves upon a firm basis. But, soon, came observations to the effect that the heart, freed from its nerves, and even when it was removed from the body, continued to beat. And in the case of cold-blooded animals the possibility of this phenomenon persisting for days was explained by postulating the existence of a motor centre in the heart. The cardiac ganglia were regarded as this centre. Subsequently, it was ascertained that an organ deprived of its ganglia still continued to beat, whence arose the theory now advanced by Engelmann and His that the cardiac muscle can work even when not dependent on nervous influence of any kind. This theory is founded on the following considerations:—

1. That the embryonic heart beats long before the presence of nerves can be demonstrated in it.
2. That there are muscular structures—the ureters, for instance—in which neither nerve-cells nor ganglia are demonstrable, and which, nevertheless, exhibit the phenomenon of contraction.
3. That, according to His junior, the cardiac nerves originate in the sympathetic system and in the process of their development grow into the heart. The heart's ganglia originate in the spinal ganglia, which must be considered as purely sensory.

Accordingly the cardiac nerves are sensory, and as such are, of course, incapable of engendering or emitting motor impulses.

4. Finally, nowhere among the terminals of the cardiac nerves are found the endings peculiar to motor nerves.

5. Leyden declared himself not competent to pronounce on the question, but the new theory seemed to him a plausible one. However, he felt bound to add that Waldeyer opposed it, maintaining the existence of motor cardiac nerves; so, too, did Kronecker and his school.

Dr. Blum, Frankfurt a/m, read a paper on

THYROID PATHOLOGY AND THERAPEUTICS.

He urged that the thyroid should be removed from the list of glandular organs. It elaborated no physiologically active secretion, but seized upon a poison continually secreted in the system by means of some capturing substance. The tissue of the thyroid thus served for the arrest of some poisonous material produced by the action of the vital processes. The activity of the fettered virus was different from that of the free toxins. By the iodising process taking place in the thyroid the harmful agent deposited there as a toxalbumen was weakened. By perfect saturation with iodine it lost its poisonous properties. The free poison caused severe and frequent epileptiform convulsions, very frequently cachexia, and sometimes distinct psychical disturbances. Examination of a dog destroyed by thyroidectomy showed changes in the ganglionic cells of the cord and brain which could be identified by Nissl's method. The disturbances when the poison was passed into the system by injection were of another kind. They consisted chiefly in alteration in tissue changes (emaciation, decomposition of albumen and nuclei, and liquefaction of the fat), restlessness and palpitation of the

heart. Convulsive conditions had never been observed. The quantity of thyroid substance absorbed could be determined by the administration of iodine. The iodine of the iodine-containing substance was estimated quantitatively. In many days the toxic effect of the thyroid substance administered still acted alternatively on the tissue change when all the iodine given had been again passed off. Such an animal when given thyroid, besides the symptoms mentioned, always had a long continuing glycosuria, and when cane sugar was given it excreted levulose. The same animal when phlorizin was given with the same diet excreted dextrose.

As regarded the so-called thyroid therapeutics in myxœdema thyroid extract might act in two different ways in the one it could relieve the organs of abnormal deposits; further, the capturing substance contained in the thyroid body could fix the freely circulating toxin in the myxœdematous individual and at last in part render it harmless. In struma and obesity the administration of thyroid was best abstained from, because while the substance was incorporated, which must be determined by the excretion of iodine in the urine, symptoms of poisoning could not be excluded. In cases of goitre other preparations of iodine, especially the non-poisonous iodine albumen (iodalbacid), should be first tried. In obesity the proper dietetic measures should have the preference.

Austria.

VIENNA, July 22nd, 1899.

THROAT AND EAR DISEASE.

THE annual reports from the different kingdoms of the Empire are rapidly coming in, and it is not uninteresting to observe the enthusiasm and activity in the different schools of medicine in which the Polish shines. Pieniazek records the history of a rhinoscleroma which he had under treatment since 1895, causing stenosis of the larynx, trachea and upper part of the bronchi. By repeated scraping and dilating the patient has greatly improved.

Seven cases of stenosis after croup, and one caused from granulating opening after tracheotomy were treated with success in a similar manner, though tampons were frequently applied.

Bronchial stenoses were treated generally by compression, iodides or drugs suitable to the cause. Among the cases were stenosis from mediastinal glandular swelling after pleurisy, tuberculous enlargement of glands and syphilis. In the latter laryngo-fissure and excision of the infiltrated glands were practised. One case suddenly collapsed while feeding with tube in œsophagus. The necropsy revealed yellow atrophy of the cardiac muscle and liver.

There are four cases of laryngeal cancer which were hard to diagnose. One arose out of perichondritis laryngea, phlegmona colli, with swelling in the pharynx. Another arose from keratoides polypus on the left vocal cord, which was excised, but soon recurred, extending deeper into the surroundings. Another instructive tumour that turned out to be carcinomatous, was that of a female with a tumour about the size of a hen's egg attached to the

left side of the soft palate. The fine pedicle which supported it being cut or torn, the tumour fell back into the throat and was swallowed by the patient. The remnant of pedicle left was removed and microscopically examined, but no trace of any adenoid tissue was to be found. Six months after another appeared with typical carcinomatous tissue.

PERITONSILLAR ABSCESS.

The same author records the history of six cases of peritonsillar abscess treated with gargle and hot fomentations. Several extended aditus ad laryngeni, in one case paralysis of the recurrent nerve followed excision of tuberculous glands in consequent infiltration.

This case is interesting from a physiological point of view, showing the effect on the soft palate of one side of the mouth after cutting the tragus.

Sedziak in his diagnosis of this disease, records the history of 8,500 cases of inflammatory condition of the fauces, root of the tongue, and pharynx, resulting in purulent accumulation, and concludes that 235 are peritonsillar in character, or 2.76 per cent. They are also affected by season, mostly occurring in the spring and autumn.

The greatest incidence is on males at the age of twenty to thirty years. It is difficult to say how far the abuse of nicotine and alcohol affect the origin. The immediate cause is the pyogenic bacteria which may be retained on the roof of the mouth till a retention of the tonsillar secretion occurs to admit germination. He has frequently seen follicular tonsillitis after influenza and muscular rheumatism, but more frequently with hypertrophy of the tonsils. Those of a lymphatic constitution are more prone to the disease. Death may occur from erosion of carotis interna, œdema of larynx, or bursting of large abscess during sleep, and suffocation.

STRUMA.

Thirty-one cases of struma are given—seventeen by compression on trachea, one by displacement towards the left, swelling of posterior surface and œdema of right arytenoid cartilage.

NASAL SARCOMA.

Among Sedziak's cases, two of nasal sarcoma of five years' standing are noticed without any effect on the surroundings, while an empyæma arbori-Highmore of secondary origin receded spontaneously.

The happy results obtained in these cases have convinced Sedziak to pause before commencing a major operation on the nose. He admitted the danger of this intra-nasal treatment in the case of sarcomatous tumours, as the constant irritation may finally lead to a cystic development.

Continental Notes.

[FROM OUR OWN CORRESPONDENT.]

URIAGE-LES-BAINS (NEAR GRENOBLE, FRANCE).

URIAGE-LES-BAINS is in the Department of Isère, formerly part of the ancient Province of Dauphiny. It is connected by two good steam tramways with the flourishing City of Grenoble; a city chiefly noted nowadays for its glove-making and its cherry-brandy! Grenoble is an important junction-station on the Paris-Lyons-Mediterranean Railway, and is readily accessible from Paris, Lyons, and Marseilles by several

different lines belonging to the great P. L. M. Railway system. Uriage is also near Aix-les-Bains, and is a convenient and excellent spot for those who have undergone "a cure" at Aix to visit for a change of scene and for recuperation. For Uriage lies in the Vaulnaveys Valley, one of the charming valleys of the Dauphiny Alps; with very interesting environs, historic, botanic, geologic, and artistic; affording easy promenades and excursions on foot, cycle, and by carriage, and with mountainous ascensions for those more energetically inclined. The steam tramways conveniently connect it with Bourg d'Oisans and its glaciers, the central point of Alpine climbing in Dauphiny.

The Uriage baths have been well described as really "sea-baths, sulphurous, and in a pine forest and mountain atmosphere;" Uriage being some 1,400 ft. of elevation. The springs here were much frequented in ancient and mediæval days, as is shown by the many remains of the old baths and buildings. For some centuries, during the troublous times of the Reformation, and of warfare between Savoy and Dauphiny, the Uriage waters were neglected; in 1820 the property came into the possession of the Saint-Ferriol family, who yet own it and have again brought it into prominence as a health-resort, valuable both for its mineral waters and for its salubrious pine-wood, mountain atmosphere as an "air-cure." Near a large garrisoned city, with its libraries, museums, military music, good shops, &c., and in a most picturesque position, Uriage is a very desirable summer home for the invalid, the rest-seeker, and the artist. Its mineral springs are unique in France, and almost in Europe, in uniting in themselves chemical principles usually found elsewhere widely separated. It is difficult to define them by the customary classifications; they are at once strongly sodic-sulphuretted-sulphurous, and sulphated-purgative. "To name Uriage," says one medical writer, "is to speak of an efficient remedy with a two-fold correlative peculiarity—peculiarity of mixture and peculiarity of indication. The water of Uriage is a powerfully mineralised one; in which has been vigorously determined the place of its efficacious medicinal elements." These waters obtained their reputation chiefly for skin-diseases acne, eczema, prurigo, tuberculosis (external), psoriasis, &c., and are found to be particularly efficacious where there exist anæmic, lymphatic, or arthritic predispositions. Their sulphurous-saline elements are also highly beneficial for the elimination of uric acid.

Uriage is strongly recommended for children, especially those residing most of the year in large cities, where colds and bronchitis are frequent, nutrition often imperfect, and growth hindered from various causes; also for hereditary tuberculosis, when not pronounced. In syphilis it is claimed to be a valuable auxiliary curative, and important in developing latent cases.

The Thermal Establishment at Uriage is open from May 25th to October 15th. It is fully equipped for all applications of the waters by the most approved scientific methods and apparatus. The water is used for drinking, baths, douches, vapour-baths, pulverisations, gargarisms, irrigations, and lotions. The pulverisations are particularly efficient in diseases of the face, eyes, pharynx, ear cavities, and chronic otorrhœa.

Uriage has numerous good hotels, pensions, furnished villas, chalets, and apartments, restaurants, livery stables, Alpine guides, and all other requisites for a com-

fortable sojourn, transient, or for the whole season. The houses in connection with the Bath establishment are "The Grand Hôtel," "Hôtel du Cercle," "Hôtel des Bains," "Grand Chalet," and the villas Juliette, Jeanne-Marguerite, Rose, Wurbee, and des Chênes; all with electric lighting. At Uriage are also the Hôtel de l'Europe (a branch of Grand Hôtel, Thibaud, Grenoble), Hôtel Monnet (a branch of the Hôtel Monnet, Grenoble), Hôtel du Midi (a branch of the Hôtel Chateaubriand, Hyeres), Hotel du Louvre, and several others of various grades and terms, so as to amply accommodate all classes of visitors.

The Operating Theatres.

CANCER HOSPITAL.

PAN-HYSTERECTOMY FOR CARCINOMA OF THE BODY OF THE UTERUS COMPLICATED WITH FIBROIDS. — Mr. BOWREMAN JESSETT operated on a single woman, æt. 56, suffering from carcinoma of the body of the uterus secondary to fibroids of the organ. She had been suffering from off-and-on hæmorrhage for about two and a-half years, and had been seen by several specialists who had recognised the fibroids of the uterus, and had held out hopes that at the menopause the hæmorrhage would stop. Just previous to admission to the Cancer Hospital she noticed the discharge to be, however, most offensive. Examination under ether and curetting the uterine cavity showed the *débris* to be of malignant nature. Mr. Jessett, therefore, recommended an operation for removal of the whole organ, but on account of the size of the fibroids, it was deemed inexpedient to attempt to remove the uterus by the vaginal route. Mr. Jessett proceeded to open the abdomen and ligature the broad ligaments, and remove the whole of the uterus by the abdomen. Iodoform gauze drainage was passed down through the vagina, and the peritoneum stitched carefully across the front of the pelvis. Mr. Jessett said that the interest of the case was that the patient had undoubtedly suffered from uterine fibroids for some considerable time, and it was considered that this was sufficient to account for the whole of her symptoms and, no doubt, this was the case; but in the present instance, as he has so often pointed out, fibroids occurring in a woman about the climacteric are very apt to take on malignant action. He had within the last twelve months operated in many similar cases on several occasions. The bearing of this fact in mind was, he thought, of the utmost importance, and he would urge on practitioners generally the necessity in all cases of women suffering from uterine hæmorrhage, either connected with the uterus or otherwise, to make a thorough vaginal examination, also, if necessary, to dilate the uterine canal, and curette the cavity of the organ, and have the *débris* carefully examined by a competent pathologist; in the event of the *débris* being pronounced malignant to at once advise the patient to submit to have the organ removed, as in these cases, when the diagnosis is made early the operation may be performed with comparative ease, and the prospect of a radical cure is most encouraging, he having at the present time several patients on whom he had operated for similar affections, alive and free from recurrence from some months to four or five years. In examining these cases he pointed out the great advantage of making a rectal examination

whilst the patient is under ether, as on several occasions the broad ligament, which, by vaginal examination, appeared to be thickened and possibly infiltrated by the disease, by rectal examination this thickening had been discovered to be caused by the presence of interligamentous fibroids or by a hydrosalpinx, the presence of which, whilst somewhat complicating the operation, by no means negatives the desirability of operating or in any way jeopardises the prospects of the patient's recovery.

The patient made an excellent recovery, and when seen some months after the operation there were no signs of recurrence.

THE STERILISATION OF MILK.

THEORETICALLY the milk of a cow proved to be free from tuberculosis and otherwise healthy ought to be a salutary and nutritious food, but in practice asepsis is impossible, and certain precautions are indispensable if milk is not to become the vehicle of pathogenic contaminations. This fact gives importance to the plan of sterilising milk, that is to say, of freeing it from all living germs capable of giving rise to disease. At the outset it is necessary to distinguish between two groups of symptoms to which milk may give rise. It may, as already stated, contain the bacteria of this or that disease, which it thus helps to spread. Boiling under certain conditions will kill the germs, but may not kill the spores, and, apart from the latter, boiling does not neutralise the effects of toxins elaborated in milk by previously existing living organisms. Milk may be kept sweet by being periodically boiled, but milk that is no longer fresh and has therefore undergone partial decomposition cannot by any known process be

rendered harmless. The gastro-enteritis of infants which so often follows the ingestion of milk, especially in hot weather, may, it is true, be due to the presence of bacteria, but, seeing that it may follow the ingestion even of milk that has recently been boiled, it is probably in many instances due to the toxins therein contained. It follows and this is a practical point worthy of attention, that milk consumers in towns far removed from the dairy of origin, who cannot therefore receive their milk until many hours after it has left the cow, cannot rely upon domestic boiling as an effectual protection against diseases due to this cause. They must consequently fall back upon milk which has been sterilised *en bloc* immediately after it has been drawn. In other words, they must rely upon the so-called sterilised milk. The technical details of effectual sterilisation are far too complicated to admit of their being carried out at home, apart from the fact just alluded to, that it is useless, or, at any rate, insufficient to attempt to sterilise milk of many hours' standing. Condensed milk, with or without added sugar, of course fulfills this desideratum so far as the freedom of the product from germs is concerned, but condensed milk is not well borne by all infants, and there are indisputable disadvantages attending the use of such products, which, when diluted, do not in all respects correspond to the formula for fresh cows' milk. There is consequently a wide field of usefulness for milk sterilised at the dairy under skilled scientific supervision since this process, if properly carried out, in no wise impairs the digestibility of the product and affects the taste and composition of the milk in a minimum degree. The conditions of efficient sterilisation may be briefly summarised as follows: The milk must be subjected either to a temperature above boiling point for a period of time extending over not less than half-an-hour, or the process must be repeated at intervals at a somewhat lower temperature. Other things being equal, a milk sterilised by repeated exposure to a temperature rather below boiling point undergoes less physical change than one which has been summarily heated under pressure, the emulsification of the fat is not impaired and the conversion of part of the casein into peptones is less apt to take place. A point to which sufficient attention has perhaps not been called, whether in sterilisation on a large scale or at home, is the absolute necessity for rapidly cooling the boiled milk. This is necessary because the temperatures intermediate between the boiling point and the normal are favourable to the rapid development of any germs which may be in, or may subsequently find their way into, the milk. Under any circumstances such milk should be consumed as soon as possible after exposure to heat. Boiling may afford a tolerably effectual protection against tuberculosis, scarlet fever, and diphtheria, but gastro-enteritis, consequent upon the ingestion of stale milk, which has already undergone partial decomposition, destroys more infant lives in one year than all the other diseases of milk origin do

in a century, hence the importance of securing fresh milk, or, failing that, of employing milk which has been efficiently sterilised *en bloc*. There are plenty of such milks on the market, and with ordinary care these afford a trustworthy and salutary food for infants.

THE METROPOLITAN ASYLUMS BOARD.—II.

IN accordance with a former intimation we propose to consider in the present article the attitude of the Metropolitan Asylums Board with regard to the housing of certain physically unfit classes of Poor-law children. As everyone knows, Mr. Chaplin's famous Order was issued in April, 1897. On behalf of the Local Government Board he directed the Asylums Board to provide accommodation for children suffering from contagious diseases of the eye, skin, and scalp; convalescents and children requiring sea air, and others of defective intellect, cripples and those remanded by magistrates. Two years and a quarter have now elapsed and it is with some interest that one turns to the Annual Report of the Asylums Board for 1898, to see what has been done. It has been estimated that accommodation will have to be provided for 2,070 children. Two sites have been purchased for ophthalmic patients, one at Swanley and the other at Brentwood; buildings have been acquired at Herne Bay and at Margate for convalescents, besides a house at Pentonville for defective children. With regard to the St. Anne's Home, Herne Bay, we believe we are right in stating that the building was originally an hotel, and that it has been already officially condemned for structural reasons. It seems likely, therefore, that in addition to the £17,000 already spent in purchase money, a very large additional sum will be sooner or later demanded for rebuilding. If these surmises be true the confidence of the public will be to some extent shaken in the wisdom of the Asylums Board. Men of business capacity would have settled the whole business off-hand, instead of dealing with it piecemeal in a leisurely and extravagant fashion. Let us take the specific case of the ophthalmic patients, who make up 800 of the 2,070 for whom accommodation must be provided. Sites have been acquired and plans adopted for the erection of schools upon the cottage house system at a cost for building and administration that can fairly be characterised as enormous. The Metropolitan Asylums Board has always spent money like water, but in this particular instance of the Ophthalmic Schools it has established a record of extravagance that is calculated to rouse even the apathetic London ratepayer into indignant protest. So far as the proposed administrative staff is concerned, the estimate seems to have been based on the fallacious view that ophthalmic patients require as liberal a proportion of nurses as ordinary "fever" patients. The total accommodation to be provided is for 712 ophthalmic patients, equally divided between two schools. Before the ratepayers are saddled with this heavy

burden for foundation and up keep it seems reasonable that the bearings of the scheme should be publicly and cautiously considered. First we would ask, how is the ophthalmic population to be kept up as the patients are gradually cured and drafted back to their own places of settlement? At Hanwell practically all the patients of the original contributing district school have been cured, and the isolation ophthalmic school has since been filled by children from other metropolitan unions. If the supply to the new Asylums Board special hospital is to depend on the voluntary action of Guardians and Poor-law medical officers, then the scheme will be likely to languish. Medical officers may or may not recognise ophthalmia, and they may or may not be unwilling to run counter to the unwillingness of the Boards of Guardians to transfer children to another authority. It seems to us that if Mr. Chaplin's scheme is to attain lasting success the transmission of infectious children to the new special hospitals will have to be made compulsory. To that consideration another equally plain proposition must be appended. In order to keep the Poor-law schools free from such cases there must be some plan of systematic skilled inspection. The necessity of those two measures was advanced in this journal on the first appearance of Mr. Chaplin's order. It is to be hoped that the Board which sanctions lavish expenditure in so many directions will not draw the line at the comparatively small sum needed for an expert whose services will go far towards securing the ultimate success of what constitutes a most salutary social movement. The recommendation was made by Mr. Sydney Stephenson in his admirable report upon the Ophthalmic State of the Metropolitan Poor-law Children in 1897. Of course it may be possible that some satisfactory method of collecting the affected children other than by the aid of Government Inspectors may have been officially adopted, and, if so, we shall be glad to hear its details. One point seems clear, namely, that if such Inspectors be appointed, in order to carry official standing and authority they will have to be officers of the Local Government Board. In conclusion, it may be remarked generally that the criticisms contained in this article are not advanced in any captious or discontented spirit. If money be needed to carry out any great public administration let it be spent generously, but at the same time with some regard to prudence. Mr. Chaplin by his energetic action has provided the London community with the germ of a long-needed reform. We trust that it will not be allowed to fall short of perfection merely by the neglect of a few obvious precautions.

GUARDIANS AND VACCINATION OFFICERS.

It must be admitted that the position of Boards of Guardians *vis-a-vis* their Vaccination Officers under the last Act is somewhat anomalous, but guardians have only themselves to thank for this curtailment of their discretionary powers. In many parts of the

country, guardians have shown themselves determined and refractory adversaries of the law, and have not scrupled to stultify the law by a policy of passive resistance. The Government, having gone the length of its tether in the matter of concessions, evidently appreciated the importance of providing an organisation which might be trusted automatically to enforce the attenuated compulsion which has been left part of the law. Such compulsion as remains is aimed at the careless and the indifferent only, for all those who feel strongly enough on the question to decline the protection afforded by vaccination, have ample opportunity of giving expression thereto. It remained to overcome the inertia which characterises the behaviour of the uneducated classes in respect of things and matters not having for object the immediate gratification of the appetites of the flesh. These reflections are suggested by the meeting of Poor-law delegates which took place in London early last week. By dint of active canvassing some forty-two boards had been induced to send delegates. The chairman was careful to point out that they had not met to discuss the question of the advisability of vaccination as a protection against small-pox, but merely to voice the indignation of Guardians at finding that their servants, the vaccination officers, were expected to act *proprio motu* in the matter of initiating proceedings against defaulters under the Act. The action of the Local Government Board was declared to be insulting to public authorities, and a resolution in favour of bringing pressure to bear on the Board was agreed to with only six dissentients. The chairman's introductory remarks are in themselves a sufficient justification for the course adopted by the Local Government Board. They (the guardians), he observed, did not wish to set their faces against the law, but as responsible to the ratepayers, and representing the principle of local self-government, they were entitled to consideration. These observations embody an exceedingly vicious principle, one against which we cannot too strongly protest. As worked out in practice, it amounts to an assertion that local self-government entails the right of individuals to set the dictates of Parliament at defiance. It is all very well for the guardians to say that it is not their intention to defy the law. Experience in the past has shown that in certain parts of the country guardians are ready and willing enough to render the law nugatory, and guardians, like magistrates, have to learn that their functions consist in carrying the law into effect irrespective of their own views or the opinions of a certain section of their constituents. We trust the Local Government Board will not recede from the position which has been taken up, seeing that reversion to the former *regime*, which left the guardians masters of the situation, would undoubtedly remove the last incentive to vaccination among the poorer classes of the community. We are threatened with a Vaccination Amendment Bill next session, but we need not now discuss its bearings.

By this time next year we shall be in a better position to form a trustworthy opinion of the effects of the concessions wrung from the Government in opposition to the almost unanimous voice of those whose opinions are worth having on such a complicated question.

Notes on Current Topics.

Legislation for Midwives.

THE reception accorded by the Lord President of the Privy Council last week to the delegation of supporters of legislation for midwives was characterised by diplomatic sympathy and extreme caution. Obviously no government would, if it could do otherwise, take upon its shoulders legislation of a kind bristling with controversial points and certain, if carried, to alienate the good wishes of a large and influential class of the community. Nevertheless, it cannot be denied that there is a large body of public opinion favourable to a measure having for object to improve the education and status of midwives. The crudeness and quasi-impracticability of the proposals hitherto brought before Parliament, have rendered it a comparatively easy task to defeat the intentions of their advocates, but the more these proposals conform to the provisions stipulated by the General Medical Council, the more difficult will it be to resist their assuming legislative form. No Government is likely to undertake the ungrateful task of forcing through Parliament a Bill on any other lines in the teeth of determined organised opposition at the hands of the medical profession, whose interests, be it remarked, are on all fours with those of the public. From every point of view the matter is one which would best be dealt with as a private bill, for this obliges its supporters to disarm opposition by timely and reasonable concessions. This is evidently what the Duke of Devonshire had in mind when he urged the delegates not to be discouraged, and advised them to prepare a measure in consultation with their critics, embodying therein all representations which they might consider reasonable. The advocates of midwives legislation may congratulate themselves on having made a decided step in advance in that they have secured an expression of sympathy on the part of the Government, but this they could have secured much earlier in the day had they shown themselves less intractable when called upon to safeguard the interests of duly qualified medical practitioners and to take precautions against the introduction of a new and imperfectly trained body of women for obstetric purposes.

The Self-Constituted Expert.

AN "expert" is always more or less an unknown quantity. He may be, indeed he usually is, a recognised authority on the subject respecting which his opinion has been solicited, but it is necessary to distinguish between the expert whose claims to special knowledge are based on tangible evidence of special

study and the *soi disant* expert whose claims to distinction fail to command assent among his fellow professionals, to whose reputation, such as it is, is due to cleverness in manipulating the lay press. We are all familiar with the names of certain people, popularly described as experts, who somehow never miss an opportunity of bringing themselves to the fore in the *causes celebres* of the hour. They do not wait for their opinions to be asked; they buttonhole the editor or one of the junior members on the staff of a London daily, and on the morrow their views are blazoned forth to the multitudes, framed in a motley array of adjectives and irresponsible encomiums, the better to justify their publication. It goes without saying that the popular experts' views must always be diametrically opposed to the professional and official views. He deliberately puts himself forward as the exponent of the views of the thoughtless, but possibly earnest, minority of the public. His name is used as a lever for bringing pressure to bear in high quarters, and so he acquires a spurious fame, "unto which he was not born." As the great public are unable to distinguish between the genuine and the spurious article, writers for the lay press are enabled to expatiate on the untrustworthiness of expert testimony, and to give examples in proof thereof. In well-informed circles, it is true, opinions are valued, not by number or by energy of expression, but by the professional status of the donors. A great deal of harm is done, nevertheless, by these irrepressible individuals, because the public are very apt to mistake notoriety for fame, and to attach an overweening importance to what a celebrated politician once called the "harebrained utterances of irresponsible frivolity."

"Vol au Chloroforme."

DOES any anaesthetist or medical expert believe any of the thrilling narratives produced by the Press of persons—almost always women—being rendered unconscious by the momentary inspiration of chloroform or any other anaesthetic? From time to time we read dramatic stories of women robbed—in railway carriages or elsewhere—of their money and jewels, or of their virtue, by an instantaneous whiff of chloroform, even by throwing into the carriage a handkerchief saturated with that anaesthetic. The possibility of this has come to be so popular a belief in France that the supposed crime is designated by a special name, "*Vol au Chloroforme*," and we have had within the last fortnight the report by a lady that she had been robbed of 70,000 francs in a railway carriage by this means. We believe we are in a position to assure the public that the production of unconsciousness by such means without preliminary violence or without consent is the next thing to absolutely impossible. We have, of course, seen young children who succumbed to the anaesthetic in a very short time—say a minute—and we can also believe that a woman assaulted in a railway carriage might from the combined influences of excitement and terror and the anaesthetic, lose consciousness in a couple

of minutes, but this could not happen without a subsequent recollection of the precedent circumstances. The public should know that to induce anæsthetic unconsciousness in an adult under the most favourable circumstances almost never takes less than three or four minutes—usually ten to fifteen minutes. The theory of the lone, unprotected female overcome by a five-second smell of chloroform administered by a man whom she cannot remember, will do for sensation newspapers, but not for the medical profession.

The Determination of Sound Direction.

THE function attributed to the semicircular canals in respect of the determination of the direction of sound has been gradually undermined, and is now more or less discredited. The nature of the mechanism by which the source of origin of a given sound is perceived, therefore, still remains to be explained. There is reason to believe that the appreciation of direction is *mutatis mutandis* very analogous to the phenomenon of stereoscopic vision, that is to say, it is in virtue of certain subtle modifications of sound as perceived by both ears that we learn to diagnose direction, just as the slightly inaccurate superposition of two visual images gives the sensation of projection. In the course of a long series of observations carried out at the Yale laboratory it was found that as a matter of fact the sense of direction is remarkably accurate, a blindfolded subject making only 113 out of 656 possible errors. It was noted that the sounds of the right hemisphere were more accurately perceived than those of the left, those from the front more than those from the rear, and those from below more than those from above, variations which are probably due to the shape and direction of the pinna, and to the difference in the functional acuity of the two ears. Distance is estimated merely by the absolute intensity of the sound, but direction is gauged, according to Matsumoto, by the relative difference between the intensities of the component sounds as heard by the two ears. This is such a delicate process that ventriloquists can, by directing the attention of his audience to a given spot other than the actual source of the sound, and by certain studied modifications of the sound emitted, mislead the judgment into overruling the impressions on the sensorium of the observer and give rise to an absolutely false perception. There remains the fact that in certain atmospheric conditions, notably in fog, the sense of direction is greatly modified, and even lost, as sailors know to their cost. This fact would tend to show that senses other than hearing are concerned in completing the impression or at any rate in confirming or disproving the deductions based thereupon.

Unsound Fruit.

FROM a medical standpoint there can be no doubt that a great deal of nonsense is talked about unsound fruit. If we accept the popular view, many, if not most, of the acute summer diseases are due to bad fruit.

Only last week, a correspondent signing as a medical man, wrote to a leading metropolitan newspaper to the effect that unsound fruit was one of the chief causes of summer diarrhoea. As a matter of fact, it is nothing of the kind. The malady in question is a symptom of invasion of the body by micro-organisms of many different kinds. It is perfectly true that those hurtful microbes may be conveyed on fruit, as they may be in any other article of food. Fruit, however, is in itself vastly less likely to carry the seeds of the infection than contaminated milk, meat, or water. Indeed, it may be fairly asserted that to attribute the incidence of this disastrous seasonal disorder to the agency of fruit is to cast round the real source of the mischief an ample cloak of ignorance. We have yet to learn that the organisms found in over-ripe or fermenting fruit have any serious disease-producing action. The point has a very serious economic aspect. Quite recently a South London sanitary inspector named Thomas has secured the destruction of enormous quantities of fruit consigned for the purpose of jam-making. It is well known that the sterilising process of prolonged boiling renders fermenting fruit harmless. In any case we should have preferred the evidence of the Medical Officer of Health offered in court upon this important point, instead of that of a subordinate official untrained in bacteriology. Messrs. Lipton and Co. would do well to have an inquiry made into the question by a bacteriological expert.

Scarborough as a Health Resort for Tuberculosis.

SINCE the open-air treatment of phthisis has come to engage so much of the professional and public mind, the health authorities of various favoured resorts have been active in claiming for their localities the advantages to be derived from following out the treatment. Under these, perhaps, natural circumstances it is not surprising that much diversity should prevail in the climates of those places which have been vaunted as suitable for the purpose. In this connection it has not been pointed out what is the best climate in which to carry out the open-air treatment. So far sanatoria are being opened or have been decided upon in all parts of the country under the most diverse conditions as to subsoil, climate, and environment generally. Nevertheless among the localities whose natural surroundings eloquently plead in its favour as a resort for consumptives desirous of undergoing the open-air treatment, mention should be made of Scarborough. There can be no question so far as our knowledge goes that this North-Eastern health resort is eminently adapted for the purpose. We believe that at present no special facilities exist for carrying out the treatment, but the matter probably only requires to be brought under the notice of the municipal authorities of the town, in order to prompt them to embark upon an enterprise which could not fail to be followed by excellent results. Naturally

favoured as Scarborough undoubtedly is for this special form of treatment, there is every reason for supposing that if the authorities were to erect a sanatorium the enterprise would soon prove a very profitable one for the ratepayers. A sanatorium under municipal control, erected and conducted in accordance with all the requirements of modern times, could not fail to prove a magnificent success. We commend the suggestion to the Corporation of Scarborough, believing that they will not lightly overlook this opportunity of again proving their ability to conduct the affairs of the town with commendable enterprise and foresight.

The Rating of Hospitals.

THE question of the rating of the hospitals is by no means so simple as it looks, and its settlement involves many principles, both legal and ethical. If the medical charities were all conducted in such a way that persons who could afford to pay private practitioners were not allowed to partake of the charitable funds, one great objection to rate-relief would be removed. Then, again, the pay system by which great charities like St. Thomas's, Guy's, and the London Hospitals in general practically trade on funds subscribed for the benefit of the sick poor. Apart from those two points, it is hard to see why anyone should object to the removal of taxation from the medical charities. However, any rate-relief must come out of the pocket of the ratepayer, and he may well object to relieving hospitals that compete with general practitioners, that give advice and medicine to the well-to-do, and that make money out of paying patients. Why should a struggling ratepayer contribute to the provision of medical necessities for folk who ought to pay for them? Government is giving a huge dole to the clergy of the established Church in the shape of a Tithes' Relief Bill. The church that nets this substantial contribution is the richest in the world, and ministers to a section only of the community. It is hard to see why a similar money relief should not be granted to the medical charities, which relieve Government of a vast mass of sickness, suffering, and disease that the State would otherwise be called upon to provide for.

Official Vaccination.

THE Vaccination Bill of last year has raised an apparently endless crop of anomalies and complications. It has been our pleasure from time to time to point out the enormous indirect compulsion that lies in the hands of the Government through the civil, military, and naval, the poor law, and the educational services. By simply announcing that the unvaccinated need not apply, the necessity of vaccination is practically enforced upon a vast section of the community. Nor could we imagine any Government that could refuse to enforce vaccination upon those engaged in the public services, an opinion we adhere to in spite of the rude shock of Mr. Balfour's surrender of the compulsory principle in the teeth of medical authority. But the anti-vacci-

nators will not be content with their victory, which will simply give them a sharper zest for future doles. They are raising a great outcry against the conditions imposed by the Education Department whereby vaccination of teachers is rendered an indispensable essential. Their attitude has been summed up thus by a writer in a contemporary journal, "A benevolent legislature provides that children need not be vaccinated, while the Education Department rules that their teachers must be. The inconsistency is as grotesque as the tyranny of the thing is outrageous." Meanwhile small-pox is practically extinct in London, and the burden of proving that vaccination has not been the chief factor in arriving at that happy result lies with the anti-vaccinators."

The "Ophthalmic Optician."

THE *fin de siècle* tradesman, the so-called "ophthalmic optician," has not by any means been backward since the Spectacle Makers' Company decided to give them the chance of gaining a diploma. In proof of this we must again revert to the advertisement columns of a contemporary. Upon this occasion it is the *British and Colonial Druggist* to which we may draw attention. In the issue of that journal for last week the following advertisement appeared:—"Classes are now being formed in Retinoscopy, Ophthalmoscopy and Ocular Physiology. Candidates prepared for the optic, dioptric and ophthalmometric grades of the British Optical Association. For terms and particulars apply to T. H. Sutcliffe, O.B.O.A., F.S.M.C., Blackpool." This announcement shows very plainly that if the diplomates of the Spectacle Makers' Company are compelled by the company to keep within certain lines in their sight-testing business, they are not bound by any restrictions by the British Optical Association. It will probably be news to the majority of our readers that opticians are now taking up retinoscopy and learning the ophthalmoscope. Practitioners may well ask, in view of these facts, what will be the end of this matter. Hazzarding a guess, we believe that trouble is in store for the Spectacle Makers' Company. In the course of time the body of "Diplomates" whom they have created will be strong enough to dictate terms to them. For example, the restriction as to advertising is not one to which the "Diplomates" are likely to submit for long, for to a tradesman business can scarcely come without advertising. Again these diplomates are forbidden to use atropine, but we gather from the advertisement above quoted that retinoscopy is now one of the branches of study of the optician, and this almost implies the employment of atropine. Altogether, it is quite possible that the Spectacle Makers' Company, or, at all events, those of the Company who have made themselves responsible for this new diploma, will subsequently find themselves in a veritable hornets' nest, and compelled to retire from the position which they have assumed. Meanwhile the Medical Acts are in such a delightfully chaotic condition that there is no

law which can prevent opticians using atropine or practising as ophthalmic surgeons if the public choose to employ them as such.

A Nursing Home Case.

OBSTINACY, like experience, has generally to be paid for, as a lady in Manchester has just found to her cost. She made an allegation against the proprietress of a nursing home in that town, to the effect that the latter was in an alcoholic condition on a particular morning when the lady paid a visit to the home for the purpose of seeing her daughter. But the allegation, however, being persisted in, there was nothing left to do for the proprietress of the home, who was a nurse, than to bring an action in order to clear her character. The case came on for trial last week, and the judge at the outset did his utmost to settle it out of court in the interest of both parties. The plaintiff, through her counsel, expressed her willingness to accept the judge's suggestion provided that an apology was tendered and the costs of the action paid. But the defendant, with an obstinacy which she probably now sincerely regrets, would not agree to this course, and the case, therefore, was heard. After the evidence had been given on both sides and the judge had summed up, the jury found for the plaintiff, and awarded damages to the extent of £50. We congratulate the plaintiff upon the result, for not only was she able to prove that the allegation was unfounded, but she has been awarded damages, the claim for which, had the case not been tried, she had expressed her willingness to forego. On the other hand the defendant has been taught a lesson which she will have good reason to remember. No possible sympathy can be felt for her, inasmuch as the evidence showed that she made the allegation in anger, and even when a favourable opportunity occurred for adjusting the matter, she obstinately refused to avail herself of it. This point was made much of by the judge in his address to the jury.

Footsoreness in the Army.

DURING the manœuvres on Salisbury Plain last year a large number of men were placed on the sick list owing to the prevalence of footsoreness. This condition was brought about as the result of the long marching, which formed part of the training to which the troops were subjected. However, active steps have since been taken, in order, if possible, to prevent the recurrence of this untoward result, and the Royal Army Medical Corps have dealt with the matter in a manner which will probably prove effectual. In the course of the end of last year at Aldershot a class of non-commissioned officers was formed and instruction given in the art and science of chiropody. This plan has so far succeeded exceedingly well in attaining the object in view, so much so that the military authorities are contemplating adopting it extensively. By its means the men are taught to look after their own feet, while at the same time any local ailments of the feet from which they may be suffering are taken in hand and cured. As might be

anticipated corns, bunions, ingrowing toe nails, chilblains, blisters, are not uncommon among the troops, and anyone of these, if allowed to remain unrelieved, would soon incapacitate a man for much marching duty. The idea of establishing a permanent system of efficient regimental chiropodists for service in infantry battalions is now under the careful consideration of the military authorities.

A New Theory of the Cause of Appendicitis.

WE would seem up to the present to have been living in a fool's paradise regarding the pathology of appendicitis. It has been usual to attribute the onset of the disease to some local disturbance of the nutrition of the appendix, generally caused by a foreign body of some sort, and frequently, when the surgeon has been called upon to interfere, and explore the seat of inflammation, a large foreign body in the appendix has been found. But a Daniel has come to judgment in this matter. Dr. Alexander Haig has affirmed that the pathology of appendicitis allows of a most simple explanation. He states that in a large number of cases inflammation in the region of the cæcum and appendix is merely a gout of the fibrous tissues of the intestines and that like gout of other fibrous tissues, it is promptly relieved by salicylate of soda or other salicylates. This is, of course, a physician's view of the matter, and physicians are rather apt to be unorthodox as to the expediency of surgical treatment in cases like those of appendicitis which really belong to the domain of surgery. In waiting for cases of appendicitis, however, to recover under salicylate of sodium valuable time might be lost, so much so that instead of gout the surgeon might find at the operation general suppurative peritonitis, caused by the rupture into the peritoneal cavity of an appendicular abscess. It is obviously risky matter to have theories upon such a profoundly active disease as appendicitis. In truth, there is no room for them; a cherry stone may become impacted in the appendix as the result of a gouty attack, but it is obvious that the patient, gout or no gout, cannot be regarded as safe until that cherry stone has been removed. Hence it would seem to be best to find out the cause of the trouble first, and then consider the possibility of gout afterwards.

Criminal Responsibility.

As a mere matter of homespun justice, it is likely that the voice of the majority of our countrymen would be raised for or against the carrying out of a death-sentence on the merits of each particular case. A cold-blooded murder, without any suggestion of mental unsoundness on the part of the perpetrator, would arouse little or no popular protest. Where there is an element of reasonable doubt, however, as in a recent case before the public, a vast agitation at once surges through the country, and the Home Secretary is urged to exercise his prerogative of mercy by the Press, by monster petitions, and even by a large and solid phalanx of the House of Commons. When doubts of so weighty and multifari-

ous a nature are raised, it would seem to be a safer course to stay the avenging hand of justice. In the case mentioned the question of the prisoner's sanity was not laid before the consideration of the jury at the trial. Almost at the same time another prisoner was at once acquitted of a terrible murder on the ground of insanity. The lady in question imagined a schoolmaster had violated a scholar, and she accordingly shot him dead. The practical point that seems to be suggested by recent events is that there should be a court of criminal appeal, which in the poisoning case, would have permitted the plea of insanity to have been adequately considered. Secondly, the need of a board of experts in lunacy to inquire into the mental responsibility of criminals of all sorts, in conditions whenever and wherever the question of insanity is raised—whether before, after, or during their trial.

Medical Millinery in Edinburgh.

THE Edinburgh College of Surgeons has yielded to the importunity of a number of its Fellows who are anxious to be allowed to advertise themselves on public occasions by assuming a gown and cap of office. The College has intimated that any Fellow can have such paraphernalia "designed and faced in conformity with the armorial bearings of the College" for £3 18s. 6d., and it "recommends that it be worn on all ceremonial occasions where the College is represented." This last limitation would be useful if it were observed by Fellows who yearn for special clothing, for it would prevent them from bedizening themselves for garden parties, charity dinners and such functions; but we predict that it will *not* be observed. Practitioners stricken with the millinery mania will probably not wait for the occasions when their college is ceremonially invited and present. Considering that up to a recent period the fellowship was purchaseable for £25, without examination, and even *in absentia*, the canonicals now adopted cannot be regarded as a badge of very superior attainments.

Mr. Stephen Coleridge and the West London Hospital.

MR. STEPHEN COLERIDGE, who, as we stated last week, endeavoured, by an appeal, to induce the subscribers to the West London Hospital to divert their contributions to the Poplar Hospital, has been placed in an ignominious position. The chairman of the Poplar Hospital has stated that if any subscriptions are so diverted, his committee are sure not to accept them. In other words, it is now quite evident that Mr. Coleridge has signally failed to do any harm to the West London Hospital by informing the subscribers to the institution that two members of the staff are licensed vivisectioners. Again, it is of interest to note that Mr. Holland utterly repudiates Mr. Coleridge's efforts on behalf of the Poplar Hospital. All this is entirely as it should be, and the National Anti-vivisection Society, of which Mr. Coleridge is the mouthpiece, have thus been administered a well-deserved snub.

Unqualified Assistants and Registration.

OUR Edinburgh correspondent informs us that one of the present features of the examinations for the licence of the Scottish Medical and Surgical Colleges is afforded by the number of candidates appearing who have filled unqualified assistant's posts during the past years, some of them for several years, but who are now compelled to become registered. Some of them exhibit certificates of attendance on classes obtained as many as ten or twelve years back. Their reappearance in the character of medical students often has an element of sadness in it, but their acquaintance with the subjects for which they come up is frequently very defective, even in such practical points as their experience of practice would lead one to expect familiarity with.

A SERIOUS case of wholesale poisoning of school-children occurred at Blackheath on Saturday last. After partaking of tea at an outing, some sixty of them were seized with vomiting and diarrhoea, the majority being taken to the Seamen's Hospital at Greenwich. All were considered sufficiently recovered before midnight, and were discharged, but the edibles and milk were taken for analysis by Dr. Hartt, the Health Officer for Greenwich.

PERSONAL.

MR. H. W. ATKINSON, of Caius College, Cambridge, has been elected to the Shuter Scholarship at St. Bartholomew's Hospital.

W. H. SYMONS, M.D. (B), D.P.H. (O), F.I.C., has been appointed Medical Officer of Health for the City and County of Bath, at a salary of £435 per annum.

SIR WM. STOKES, M.D., F.R.C.S.I., Surgeon-in-Ordinary to the Queen in Ireland, has been appointed an Honorary President of the International Medical Congress, to be held in Paris next year.

THE appointment of surgeon to in-patients at the Westminster Hospital, void by the retirement of Mr. Thos. Bond, F.R.C.S., has been filled by the election of Mr. Alfred Tubby, F.R.C.S., and Mr. E. Percy Paton, F.R.C.S., has been appointed assistant-surgeon.

DR. MAX BREUER, a German subject, formerly surgeon on the s.s. *Russia*, has just been made a Knight of the Legion of Honour, for having eight years ago rendered surgical assistance to a French sailor on an English petroleum ship, on the high seas, under peculiarly trying circumstances. *Mieux vaut tard que jamais!*

WE are glad to be able to report that Sir Thomas Grainger Stewart, Professor of Clinical Medicine in Edinburgh University, has made considerable progress towards recovery within the last few days, although it will necessarily be some time before he is able to fulfil any engagements of any description. It is to be hoped that the long vacation will afford him the rest he is so much in need of, and enable him to undertake the work of next winter with his health completely restored.

It is proposed to build at Aix-le-Bains a hospital for the poor as a memorial to the late Dr. Brachet. The French Government has promised its assistance. English friends of Dr. Brachet who may desire to subscribe are requested to send their contributions to Mr. F. D. Mocatta, of Connaught Place, W.

Correspondence

THE NATURE AND TREATMENT OF WHOOPING-COUGH.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In your article on the Metropolitan Asylums Board in this week's number of THE MEDICAL PRESS AND CIRCULAR, the words "the terribly fatal maladies, whooping-cough and diarrhoea," occur in reference to the possibilities of some day dealing with them as infectious diseases.

Now, it has always appeared to me difficult to understand why it has taken so many years to make our profession perceive the nature of whooping-cough. My old friend, Dr. Octavius Sturges, *thought* I had some reason for my views, but as Dr. Sturges did not go through fifteen years of out-patient work in those crowded rooms at the Great Ormond Street Children's Hospital, I made allowance for his sceptical attitude. But I cannot reflect on this subject without recalling an amusing incident that occurred in the family of one of the most, if not the most, distinguished anatomists in London. His children had whooping-cough, and the advice of Dr. Niemeyer that the treatment of a birch rod might prove of effect was suggested, not by myself, but by another friend well-known as a children's doctor. A few weeks passed when the mother of the family caught the whooping-cough, and her eldest son recalled to her mind the advice of Dr. Niemeyer. That eldest now is a well-qualified practitioner, and an interval of between fifteen and twenty years has, I am glad to see, cleared up the great ignorance that prevailed in our profession on the nature of whooping-cough, and which, I hope, will lead as your article suggests, to some steps being taken to prevent its spread. To see thirty or forty children in the Ormond Street waiting-rooms mixed up with others was not pleasant.

I am, Sir, yours truly,
ROBERT LEE.

39, Gunterstone Road, West Kensington, W.,
July 21st, 1899.

THE CANCER "FOG."

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Barnum tells in his "Autobiography" the story of a clever young lawyer who was pleading in his first cause, and had made a long and eloquent speech greatly to his own satisfaction. That was somewhat damped, however, when the judge asked him for which side he appeared—plaintiff or defendant?

I was reminded of this anecdote when I read the first letter of your correspondent, "Philosophus Ignotus"; for his opening remarks coincided so exactly with my own views, expressed or implied, that I could not see where the prospective censure was to come in. Such phrases as—"The philosopher's function to try to see," "principles." "I think careful and accurate observations are not so much a desideratum now as sound reasoning, judgment, and reflection founded on them." "It is not more observations that we require in the study of cancer, but a better use of the observations we already have," "No memory is so prodigious as to be able to carry it (the mass of recent medical observations); for one is in great danger of failing to see the wood for the trees," are aptly expressed propositions, perfectly after my own heart, and with which, making one slight reservation, I fully concur.

That reservation concerns the words I have above italicised. For however enormous the aggregate of details and of more or less isolated facts with which we have to deal, it is idle to pretend that we really have more than a child's empirical knowledge about any single medical, physiological, or pathological point that can be instanced. Sir Isaac Newton described himself as "a child picking up pebbles on the sea-shore." That is a simile we should all do well to bear in view, especially in the existing state of medical education. The student's brain is crammed to repletion with facts, or what pass for such. He is never supplied with any general law or principle which binds these together, by which their truth may be tested, and which enables them to be put to practical use. It is not even suggested to him to look for such a principle, which must needs be underneath them somewhere; or that, if he would become other than a mere empiric, he must search until he find it. So long as he can commit to memory a sufficient number of particulars, and reel them off to order at an examination, that is all which the present system requires. Hence, a frightful waste of force in the process of manufacture; a standard of quality far below what should be found in the finished article.

In the department of cancerous diseases there have been, of course, as my paper pointed out, very numerous and valuable observations. Were these, as your correspondent justly hints, carried into practical effect, the progressive mortality would soon be very appreciably diminished. But it is futile to pretend that we have enough for the purpose, and that no more are needed. We know perfectly well, the immediate antecedents—in other words, the exciting causes—of cancerous disease, whatever the variety. *No cancer ever arises without a definite and ascertainable excitant in each individual instance.* Only it is not permissible to discuss "cancer" as a single malady. It is a very large group of maladies, each widely differing from the rest, in mode of causation, to say nothing of clinical and pathological phenomena. The recognition of this maxim is the first step towards reform in medical literature and towards the foundation of any true cancer-science.

Your correspondent implies, and the lay press take for granted, that the causes of "cancer" are obscure and unknown. That is entirely erroneous. There is nothing mysterious about them. There is, indeed, a mystery, but it is purely teleological, relating to the qualities of protoplasm and the relation of individual cells to the nervous system. Here observations are wholly wanting. I doubt whether there can be material scientific progress until this wholly unknown country has been explored. The physiology and pathology of unicellular organisms, such as the *Amœba* and its congeners, will some day be found of profound significance in elucidating those phenomena characterising malignancy in all its forms, which I have ventured to designate collectively "The Cancer Process."

Another most important matter on which independent investigations are urgently needed, is the behaviour of the lymph-glands towards cancer-protoplasm. In the *Medical Press* of November 9th last, I pointed out that in the early stages of all, or nearly all, malignant lesions, extensive destruction of the infective cell-particles takes place, either in these organs or in the lymph-current; most probably the former. Of this I feel perfectly certain, no other explanation will account for the clinical phenomena.

It seems to me that the fact might reasonably be turned to therapeutic use; nay, that we might even discover something in the nature of a remedy. But a long series of careful observations and experiments is an indispensable preliminary to any valid work.

I fail to see that any object would be gained by discussing the long string of interrogatories in your correspondent's second letter; even if I could discern their bearing upon the questions at issue, which is not the case. But he blames me for not stating facts, and giving the result of my own observations. If he will only do me the honour of referring to any one of my publications, the result of a life's work, I think he will discover a reasonable supply of facts. And if he would condescend to explore a little further, he would find every

question answered somewhere or other; without occasion to invoke "pollaki-siteism" or "polysiteism" and so to send us on a tedious search after the long-disused Greek lexicon. The series of 1075 cases analysed in reference to the question of heredity, would offer support to his own views on the non-validity of that factor as a source of cancer-development.

But alas! I am here reminded of a shrewd remark Sir Walter Besant somewhere makes about clever magazine articles. They are read, people talk about them perhaps, for a couple of days. Then the world goes on as though that article had never been written. So it is with any work or paper not involving a mare's nest on cancer. The only difference is that nobody takes the trouble to read the latter.

I am, Sir, your truly,
HERBERT SNOW.

6, Gloucester Place, Portman Square,
July 22nd, 1899.

THE TEMPERANCE QUESTION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR.—May I ask for space to reply to the extraordinary article on "The Temperance Question" in your last issue? It so (apparently without the least intention) caricatures the total abstinence movement that one cannot but wonder that in these enlightened days anyone should have such notions about it. What, for instance, can be the meaning of the sentence, "The evils of excess in some are not very clearly proved to be curable by total abstinence in others"? I never heard of anyone who prescribed such vicarious treatment. It goes without saying that if a man abstains he cannot be drunk. If A. is the drunkard A. must abstain, and all the good B. can do A. by abstaining too is to encourage him and make it easier. But B. abstains, not simply because A. drinks, but (1) because it is better for himself physiologically; (2) because he does not want to be like A; and believes that total abstinence is the only absolute guarantee; (3) because he helps to break through and break down the drinking customs which have led A and so many others to become a drunkard.

Then the writer sneers at "religion" in connection with the cure and prevention of drunkenness. One fails to see why. For (1) the crusade against drink and drinking has been chiefly carried on by men from or with religious motives; and (2) why refuse the help of the strong motives which religion supplies in curing the drunkard? They certainly have their place and power.

One must pass over much that is irrelevant in the article, even if true, but the writer calmly defies logic in stating that Nature, by fermentation, provides us with the means of changing certain substances from one condition to another to make them more suitable to the human body. To prove that fermented drink must be beneficial, he instances the advantages of fermented bread! Surely he must know that the object of fermenting dough is to produce the bubbles of CO₂, which render the bread light, and that the production of alcohol is not the object, this product being expelled in baking. Will he maintain that alcohol is more suitable to the human body than sugar, or than starch? The absurdity of it precludes serious argument.

Then, again, he credits abstainers with the notion that "nothing which Nature provides us with should be used for good if it can possibly be used for ill." One might ask, and ask in vain, for the alcoholic beverage which Nature provides without human interference. Everyone knows that if Nature starts the process of fermentation, and is not let or hindered, the ultimate product is vinegar, &c., and not an intoxicating beverage. We do not object to any good thing, but we require proof that alcohol is good (for internal use), and we are convinced that even if there were some good to be obtained from taking it (pleasure, &c.) the evils which accompany are so inevitably and inextricably mixed with the good that "the game is not worth the candle."

Where can he have got the idea that we regard total abstinence as a virtue? We disclaim it altogether. We regard it as nothing more than common-sense to abstain

from a drug (alcohol, and the drinks which contain it) which renders the practice of the virtue temperance (i.e., self-control) more difficult, and which curtails or abolishes it in hundreds of thousands of cases, every day, to the manifest injury both of those who take it and those who have to do with them.

By all means treat this question as one of sanitary science, and in the same manner that other sanitary questions are treated. Sanitarians advocate that food and drink should be as pure, nutritious, and free from poison as possible. No one in his senses will advise the use of slightly impure water when an abundant supply of pure is available. Should we say "A little won't do much harm, but don't take too much?" We are consistent in advising total abstinence from all poisons, and especially from alcohol, which by its insidious power has done and is doing more harm than all other poisons put together.

The profession know that this is all true, and as soon as they are prepared to speak out the truth, the public will follow and have a better opinion of them.

I am, Sir, yours truly,
J. J. RIDGE,

Hon. Sec. British Medical Temperance Association.
Enfield, July 22nd, 1899.

THE ANSELL POISONING CASE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR.—Although it is impracticable to attempt to draw a line of demarcation between insanity and criminal responsibility, it appears to me, *prima facie*, that the Home Secretary was ill-advised by the experts who examined the condemned in this case; otherwise the capital sentence would have been commuted. It is true a premeditated and diabolical murder was committed for the purposes of trivial gain. On the other hand, the pronounced family history of insanity, the early eccentricities of the condemned (as you remark) and terrible family history, coupled with the inadequacy of motive, clearly point to an abnormal mental condition, apart from the individuality of the case, and which according to the present tone of English society and public opinion should have absolved the condemned from criminal responsibility.

I am, Sir, yours truly,
CLEMENT H. SEES.

Queen's Road, Peckham, July 21st, 1899.

HOSPITALS AND THE ANTI-VIVISECTIONISTS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR.—With reference to your article entitled "The London Hospitals and the Anti-Vivisectionists" I never suggested, nor did I use any words that could imply a suggestion, that Drs. W. A. Turner and G. L. Cheate "made use of the West London Hospital Laboratory for the prosecution of their (vivisectional) researches."

I made a plain statement that those two gentlemen were licensed vivisectioners and were on the staff of the hospital. Mr. Bird, the chairman of the hospital, wrote to the papers claiming the support of the humane, and fortifying his claim by asserting that vivisection did not go on at his hospital. If he may claim support on that specific ground, why may I not point out that there are vivisectioners on the staff?

And there being another hospital that is without that stigma in the eyes of anti-vivisectionists, why may I not name it?

If vivisection is a proper adjunct to a hospital, let those hospitals that foster it appeal to the public on that very ground for their support.

If it be not a proper adjunct to a hospital let those hospitals that have nothing to do with it at least have the advantage that may accrue from such disconnection.

The National Anti-Vivisection Society has a perfect right to use its influence openly and fairly to direct the subscriptions of the benevolent towards hospitals disconnected with vivisection, and it will certainly continue to do so.

The suggestion that you seem to make, that in fulfilling

this obvious duty to its supporters, the Society, and myself as its representative, are doing something discreditable is perfectly ridiculous.

I am, Sir, yours truly,

STEPHEN COLERIDGE.

20, Victoria Street, London, S.W.,
July 21st, 1899.

THE MEDICAL DEFENCE UNION AND MEDICAL AID ASSOCIATIONS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In consequence of the resolution passed by the General Medical Council on June 6th, in *re* medical aid and other associations the council of the Medical Defence Union has decided in future to require intending candidates for membership of the Union to sign the enclosed declaration in addition to the usual application form. As a matter of interest to the profession, may I ask you to kindly afford space in your columns both for this letter and the declaration itself?

I am, Sir, yours truly,

A. G. BATEMAN.

Medical Defence Union, 4 Trafalgar Square, W.C.
July 21st, 1899.

The declaration reads as follows:—

"I hereby declare that I do not at the present time hold any office in connection with any medical aid or other institution in which systematic canvassing is practised as a means of procuring patients, and that in the event of my being elected a member of the Medical Defence Union I will not during the continuation of my membership thereof accept any offices whatsoever in or be otherwise associated with any society, association, provident dispensary, or medical institution where canvassing for the purpose of procuring patients is practised; and I further declare that I will not engage in any practice either as principal, partner, or assistant in which canvassing for the purpose of procuring patients is adopted."

THE PROPOSED BOARD OF CONCILIATION.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—We may not be all of one mind with reference to the proposal of the General Medical Council to form a Board of Conciliation, but we shall all be agreed that the proposal is worth the careful consideration of the medical officers of the Friendly Societies of this country.

May I suggest that the annual meeting of the British Medical Association affords a very fitting opportunity of discussing this important subject

I am, Sir, yours truly,

T. GARRETT HORDER.

Cardiff, July 21, 1899.

Medical News.

Dental Hospital of London.

ON Wednesday last a conversazione was held by the Dental Hospital of London at the Royal Institute Galleries, Piccadilly, when the prizes of the School of Dental Surgery were distributed to the successful students of the year by Sir Richard Douglas Powell, the most successful students being Mr. J. T. Carter, Mr. W. J. Duncalf, Mr. A. Rice, Mr. E. Rhodes, and Mr. G. C. Sawday. Mr. Morton Smale, the Dean, remarked that the school had attracted a large number of students, including some from Italy, and their students had carried away several important prizes at the general hospitals. The new premises in Leicester Square were progressing, and the hospital would be in full working order in October. Sir Richard Douglas Powell said that through the efforts of the staff during forty years the hospital had advanced to a great state of perfection both in its teaching and in the administration of relief. When adequate room was obtained in the new building, with the museums and teaching power that now

existed, the institution should be second to none in the world, and he believed that the students and prize-winners would carry on the good work of their predecessors.

The Sixth International Otolological Congress.

AN interesting programme has been issued for this Congress, which will be held at the Examination Hall, Victoria Embankment, W.C., from August 8th to 12th. Over seventy papers are announced for reading, besides a general discussion on "Indications for Opening the Mastoid in Chronic Suppurative Otitis Media," to be opened by Profs. MacEwen and Politzer, and Drs. Knapp and Luc. The museum, to be held in connection with the Congress in the same building, promises to be of great interest. There will be a large collection of specimens relating to diseases of the ear and nose, not only from this country, but also from France, Germany, Austria, Holland, and other countries. Among others, Prof. Politzer (Vienna) is bringing over many valuable specimens. Members of the profession will be admitted to the museum, on presentation of their visiting cards, on Wednesday, August 9th, and on Thursday, August 10th, from 2 to 4 p.m., and on Saturday, August 12th, from 10 a.m. to 5 p.m. Further particulars of the Congress may be obtained from the Hon. Sec.-Gen. Mr. Cresswell Baber, 46 Brunswick Square, Brighton.

Irish Medical Schools' and Graduates' Association.

THE summer general meeting of the association will be held on Wednesday, August 2, 1899, at the Town Hall, Portsmouth, in Committee Room No. 1 at two p.m. the president, Sir William Thompson, M.A., F.R.C.S.I., in the chair. Dr. George Stokes has given notice that he will move the following resolution, viz.: "That the last sentence but one of the first paragraph of Rule VIII. be altered to read as follows:—"Of the elected members of council twelve only shall be eligible for re-election." The Chairman of Council will report the decision of council as to the "coming of age" celebration to take place in London at the commencement of the winter session.

Westminster Hospital Medical School.

THE following were the principal awards at the distribution of the prizes at this Institution for the Winter and Summer Sessions:—Scholarships in Arts, each of the value of £50, to C. Fletcher and G. W. Heron. Oxford and Cambridge Scholarships, each of the value of £40, to A. R. Roche, F. P. Edwards, and B. J. Dudley. Science Scholarships, each of the value of £30, to C. Roper and M. J. Cromie. Dental Scholarship, value £20, to L. W. Townsend. The Chadwick prize, value 20 guineas to A. J. V. Betts. The President's prize, value 20 guineas, to E. C. Whitehead. The "Bird" medal and prize, value £14, to H. D. Brice. Histology prize, E. C. Whitehead. Practical Chemistry prize, E. C. Johnson. Prize for Materia Medica, W. Payne and H. D. Brice. Midwifery prize, E. R. Carling. Medicine prize, W. Payne. The prizes having been presented, Sir John Wolfe Barry delivered an address, in which reference was made to the value of examinations as a guarantee to those entering a profession of their being *au courant* with all that is known in scientific research. But practical knowledge could never be met by any system of examinations, and in the medical profession must be acquired by clinical study in the hospital. The position taken by the school in the public examinations was referred to as comparing favourably with that of the larger medical schools. The records of old students were mentioned. Sir George Robertson, the hero of Chitral, had been a student at Westminster Hospital, and Messrs. Walker, White, and Jerman were now in Uganda upholding the high quality of the Westminster Hospital Medical School training.

London Hospital Medical College.

OCCASION was taken of the presentation of prizes and certificates gained by the students during the past year to formally open the new buildings of the medical school by Lord Knutsford, on July 18th. The following is a list of the prizes:—Price Entrance Scholarship in Science: £120, Mr. F. W. Jones. Price Entrance Scholarship in Anatomy and Physiology: £60, Mr. L. Bousfield. Entrance Science Scholarships: £60, Mr. J.

W. Fox; £35, Mr. J. J. Rainforth. Buxton Scholarships (Arts): £30, Mr. M. Greenwood. Epsom Scholarship (for Students of Epsom College): £126, Mr. C. Colmer. Scholarship in Clinical Medicine: £20, Mr. J. Sherren. Scholarship in Clinical Surgery: £20, Mr. A. Killick. Scholarship in Clinical Obstetrics: £20, Mr. R. J. Howard. Duckworth Nelson Prize: £10, Mr. R. J. Howard. Letheby Prizes in Chemistry: Senior (£20), Mr. H. E. Ridewood; Junior (£10), Mr. G. O'N. Waddington. Sutton Scholarship in Pathology: £20, Mr. R. N. Salaman. Scholarship in Anatomy and Physiology: £25, Mr. H. E. Ridewood. Scholarship in Anatomy and Biology: £20, Mr. F. W. Jones. Minor Surgery Prizes: £15 prize, Mr. A. J. Couzens; £10 prizes, Mr. E. J. H. Rudge and Mr. T. Y. Simpson; £5 prizes, Mr. H. R. Cran, Mr. W. G. H. Cable, and Mr. M. R. Johnson; £3 6s. 8d. prizes, Mr. G. Birch, Mr. G. M. Clowes, and Mr. T. W. Jeffery. Practical Anatomy: £6 prize, Mr. R. A. Dolbey; £4 prize, Mr. H. M. Churchill. Anderson prizes: £2, Mr. W. H. Davidson and Mr. R. F. Williams; £1, Mr. B. Warren, Mr. D. S. Skelton, Mr. H. Balean, Mr. F. Challan, and Mr. A. B. Soltan.

St. Bartholomew's Hospital Medical School.

The following Scholarships and Prizes for the past winter and summer sessions have been awarded:—Entrance Scholarships.—£75, in Biology and Physiology, L. J. Picton; £150, in Chemistry, Physics, and Biology, C. C. Robinson and J. Burfield, equal; £50, preliminary Scientific Exhibition, A. F. Forster; £20, Jeaffreson Exhibition, T. Jeff Faulder; £50, Shuter Scholarship, H. W. Atkinson; £50, Junior Scholarships in Anatomy and Biology, A. Hamilton, T. H. Harker, and C. C. Robinson, equal; £40, Junior Scholarships in Chemistry, Physics, and Histology, H. V. Wenham and E. C. Williams; £5, Treasurer's Prize in Practical Anatomy, C. C. Robinson. Certificates—A. Hamilton, J. Burfield, W. S. Aldred, T. W. Chaff, J. W. Cleveland, A. J. Foster, T. H. Harker, and H. V. Wenham; £50, Senior Scholarships in Anatomy, Physics, and Chemistry, F. Grone; £26, Foster Prize in Practical Anatomy, N. E. Waterfield. Certificates—W. P. Yette, H. E. Stanger-Leathes, H. R. Kidner, J. Corbin, F. H. Noke, T. C. Melville, E. B. Smith; £3 6s., Harvey Prize, in Practical Physiology, N. E. Waterfield; Prox. Acc., H. B. Kidner; £5, Wix Prize, for an Essay on the Life and Works of Matthew Baillie, E. C. Williams; £8 10s., Hitchins Prize in Butler's Analogy, S. G. Mostyn; £10 10s., Sir George Burrow's Prize in Pathology, G. V. Bull. £13 13s., Skynner Prize, in Regional and Morbid Anatomy, including their reference to Scarlet Fever, &c., Howell Davies; £20, Matthews Duncan Prize in Obstetric Medicine, C. J. Thomas; £30, and Gold Medal Kirkes Scholarship, and Gold Medal in Clinical Medicine, C. J. Thomas; £39, Brackenbury Scholarship in Medicine, C. J. Thomas; £39, Brackenbury Scholarship in Surgery, F. C. Borrow.

School of Medicine for Women.

The science laboratories at the London (Royal Free Hospital) School of Medicine for Women will be completed and fitted up in time for the opening of the winter session. This will allow of classes being held for the preliminary scientific examination of the University of London, which has been impossible hitherto owing to lack of space.

University of London.

At the Intermediate Honours Examination in Medicine during July, 1899, the following candidates passed:—

Anatomy.—First Class: *William Percy Gowland (Gold Medal), Owens College; Charles Seymour Parker (Exhibition and Gold Medal), University College.

Second Class: James Alane Coupland, Yorkshire College; Reginald Cheyne Elmslie, St. Bartholomew's Hospital; Greer Edmund Malcolmson, Owens College.

Third Class: William Henry Bowen, Guy's Hospital; James Cameron, Edin. Univ. & Sch. of Royal Coll.; William Thomson Crawford, University College; Ernest Nicholson Cunliffe, Owens College; Charles Edward Ham, London Hospital; Anna Maude Smith, London School of Med. for Women.

Physiology and Histology.—Second Class: Myer Coplans, Guy's Hospital; Harold Edward Ridewood, London Hospital.

Third Class: William Henry Bowen, Guy's Hospital; William Henry Harwood-Yarred, B.Sc., St. Thomas's Hospital; Albert Ernest H. Pakes, B.Sc., Guy's Hospital; Louis E. Stamm, B.A., B.Sc., Guy's Hospital; James Ernest Stratton, University College; George Ernest Waugh, Cambridge Univ. and University Coll.; Owen Thomas Williams, University College, Liverpool.

Organic Chemistry.—First Class.—Reginald Cheyne Elmslie (Exhibition and Gold Medal, St. Bartholomew's Hospital); *William Henry Harwood-Yarred, St. Thomas's Hospital; Harold Edward Ridewood, London Hospital.

Third Class: Agnes Catherine Scott, London School of Med. for Women.

Materia Medica, and Pharmaceutical Chemistry.—First Class:—Ernest Rock Carling (Exhibition and Gold Medal), Westminster Hospital, King's College, and Birkbeck Institute; Reginald Cheyne Elmslie, St. Bartholomew's Hospital.

Second Class: Ernest Nicholson Cunliffe, Owens College; Greer Edmund Malcolmson, Owens College; Ernest Eric Young, St. Bartholomew's Hospital.

Third Class: Alexander Clarke Begg, Edinburgh University and School of Medicine; William Henry Bowen, Guy's Hospital; James Cameron, Edinburgh University and School of Royal Colleges; Charles Edward Ham, London Hospital; Anna Maude Smith, London School of Medicine for Women.

* Obtained the number of marks qualifying for the Exhibition.

Royal College of Physicians, Edinburgh; Royal College of Surgeons, Edinburgh; and Faculty of Physicians and Surgeons, Glasgow.

The Quarterly Examinations for the Triple Qualification in Edinburgh were concluded on the 20th inst., with the following results:—

First Examination, 4 Years' Course.—Of 6 candidates entered, the following 4 passed the examination:—

Gilbert Elliot Aitken, Nicholas Philipson, William Henry Burnhill, and John Wilson; and 1 passed in Elementary Anatomy, and 1 in Chemistry.

First Examination, 5 Years' Course.—Of 32 candidates entered, the following 13 passed the examination:—

Minnie Green, John Searle Burton, Leo Levi, Reginald Herbert Brierley, Evelyn Morris Franklin, Tom Bragg, John Mulvihill, Gerety, Robert Walter Joseph Pearson, John Dick, John David Jones, Michael Bernard Conroy, William Pearson Cowper, and Samuel Ethelbert Mangenie; and 8 passed in Physics, 8 in Biology, and 1 in Chemistry.

Second Examination 4 years' Course.—Of 8 candidates entered the following 5 passed the examination:—

Nicholas Philipson, Selby Woodhouse Morton, William Smith, Thomas Edward Frazer Toovey, and Theodore William Rhoades; and 1 passed in physiology and 1 in materia medica.

Second Examination 5 years' Course. Of 31 candidates entered, the following 21 passed the examination:—

Thomas Longmore Ashforth, Martin Francis Cusack, Frederic John Scrimgeour, Robert Douglas Argyll Douglas, Edwin Wrigley Kemp, Thomas Sargeant Pearce, Anne Low Venters, Andrew Young (with distinction), May Thomson, Robert Chisholm, Charles Wilfred Coghlan, Thomas Huston, Percy Howe, John Walker Wood, Charles Stewart Hunter, Robert Bathgate Johnston (with distinction), William James Noble Todd, Robert Stratford Stephens, Peter Carruthers Watt, Robert Sutherland Mackintosh, and John O'Connor, and 2 passed in Anatomy and 1 in physiology.

Third Examination, 5 years' Course. Of 25 candidates entered, the following 20 passed the examination:—

Edith Maria Lydia Scull, William Charles Bentall, Alfred Augustus Beeks, Frederick Alexander Georgeson, M.A.; Raoul Ferdinand de Boissiere (with distinction), Frederick Charles Willmot, William Stephen Cowin, David Patrick Johnstone, Bernard Flood, Norman Lang Stevenson, Agnes McLean Rolland McNab, Neil Murphy Gavin, Archibald Macqueen, Arthur Ernest Whitehead, Mary Brice Carr, James Campbell Nicholson, Thomas Arthur Ball Harris, Walter Goldsworthy Edwards, John Hogan Rooney, and Kallyani Pado Chatterjee, and 2 passed in Materia Medica.

Final Examination.—Of 87 candidates entered, the following 43 passed the examination, and were admitted L.R.C.P.E., L.R.C.S.E., and L.F.P. and S.G.:—

Anne Mercer Watson (with honours), George Frederick Stooke, Herbert Alfred Hillman, John Searr, Lewis Augustus Clutterbuck, Robert Hugh Russell McKean, John Brangan, George William Hardie, Frank Randolph Seager, Joseph Freeman, Rowland William Devey, Horace Gordon Lewer, John Colin Campbell Ford, Robert Boles Sandiford, Guy Verney Fletcher, David Coffey, Patrick Coffey, Henry Heber McWilliams, James Patrick Lavery, Ernest Augustus Boxer, James Gerald Sheahan, Winifred Muirhead, Euphemia Stoker, Patrick Heffernan, Joseph Eugene, Horace Gentil, Mary Birrell Davies, John Noonan Meade, Nicholas Philipson, Jeannie Hamilton Traill, Joseph Dalrymple, John George Grant, Edmund Patrick Kelly, Abraham Johannes Benjamin Albertyn, Rosalie Berthon, Robert Paterson, Dhanaindranathia Mittra, Pareh Ranyan Roy, Martin Joseph Lobo, Gregorio Manoel Horatio de Souza, Thomas Edward Frazer Toovey, Bhagvant Sakharan Patkar, James McMurry, and William Frederick Campbell, and 5 passed in the division of Medicine and Therapeutics, 1 passed in the division of Surgery and Surgical Anatomy, 11 in the division of Midwifery and 11 in the division of Medical Jurisprudence.

Royal College of Surgeons, Edinburgh.

The following candidates having passed the requisite examinations were, on the 20th inst., duly elected ordinary Fellows of the College:—

John Charles White Halliday, M.B., C.M., Univ. Syd., L.R.C.S.E.; Thomas Ranken Macdonald, L.R.C.S.E., M.B., C.M. Edin.; Hugh Robertson, M.B., C.M. Glasg.; Walter Archdale Sharpin, M.B., C.S. Eng., L.R.C.P. Lond.; John William Steven, M.B., C.M. Edin., L.R.C.S.E.; John Stevenson, M.B., C.M. Edin.; William Macrae Taylor, M.B., C.M. Edin.; Francis Pensonby French, M.B., C.M. Edin.; Philip George Williams, M.R.C.S. Eng., L.R.C.P. Lond.; and William Gordon Hanna, was admitted a licentiate.

Notices to Correspondents, Short Letters, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initial*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

"THOSE DEVILISH VIVISECTORS."

We have received the following communication from a gentleman whose name we were unable to find in the *Medical Register*, and who appeared to be connected in some way with a hospital equally obscure.

To the Editor of the MEDICAL PRESS and CIRCULAR.

Sir,—I am afraid you are not enterprising. If you want to know what I am look in the Clerical Directories and you will see. And as to this Institution, it is not a place for harbouring helpless mortals, who shall form "clinical material" for vivisectors to sport with, but for giving shelter to people without any such evil accompaniment.

As to my right to speak of vivisection, I may say that I have followed very closely for eight years or more the doings of the experimenters on living animals, and I hold strongly to the opinion that the experiments are misleading as to what they teach, and in themselves barbarous. I may say of many of them that they are of a devilish nature, and if the British public were not deceived by the Report on Vivisection issued to Parliament from the Home Office, my opinion would be endorsed by the nation as a whole.

Perhaps you will give this note a conspicuous place in your journal?

I am, Sir, yours truly,
J. STANTON.

Wokingham, July 21st, 1899.

DR. GILBERT E. BROOKE (Turk's Island).—We thank you for the photograph which, though artistically interesting, is hardly suitable for the purpose suggested.

A COUNTRY DOCTOR (Cornwall).—We fail to see the point of your objection. Of course you may be perfectly correct in your view that the joint affections of gonorrhoea are merely manifestations of the absorption of the irritative products of the specific micro-organisms. On the other hand, however, we have the suggestive fact that the gonococcus has been repeatedly found in the effusions into the joints of gonorrhoeal rheumatism. Curiously enough the organisms are rarely to be found in the sheaths of tendons inflamed under similar circumstances. It is hardly too much to say that modern bacteriology has enabled the physician to approach the question of rheumatism generally from a new scientific standpoint. Much remains to be learnt about the behaviour of the vagrant gonococci. Scarlatina rheumatism offers another suggestive field of study. We congratulate you on your philosophical speculations.

NOCTURNAL INCONTINENCE OF URINE.

To the Editor of the MEDICAL PRESS and CIRCULAR.

Sir,—In answer to the request of your correspondent in your issue of June 7th, I would advise that the bladder be filled almost to distension with a weak solution of chloretone, of the strength of about one part to 125 (8 grams to one litre), the solution having a temperature of about 100 deg. F. Chloretone is a new product, having a definite chemical formula, being a combination of chloroform and acetone. It occurs in the form of a white crystalline solid, sparingly soluble in water. It acts as a local anæsthetic, and is entirely free from toxic or other untoward effect. Moreover, it is a powerful antiseptic, and its action in my hands has proved highly satisfactory. Internally, I would recommend the use of the sulphate of strychnine, in gradually ascending doses, and the oils of santal and saw-palmetto.

I procure the chloretone and globules of saw-palmetto and santal oils from Parke, Davies and Company, and as they have an establishment in London I presume the medicines can be procured there.

I am, Sir, yours truly,
CUVIER R. MARSHALL, M.D.

1505 Woodward Ave., Detroit, Mich.

THE LIVERPOOL SAMARITAN HOSPITAL FOR WOMEN, AND THE LATE MR. LAWSON TAIT.

In our last issue we noted with surprise that the committee of the above hospital had at its annual meeting "elected Mr. Lawson Tait to be consulting surgeon" several weeks after that distinguished surgeon had passed away. Dr. G. A. Hawkins-Ambler writes us that the late Mr. Lawson Tait had been consulting surgeon to the hospital since its establishment some two or three years ago, and had taken the warmest interest in its progress. The mistake, he says, occurred in the report of one of the Liverpool newspapers, and singularly enough in the one which contained a lengthy obituary article on the deceased surgeon. It probably arose from the reporter present copying the names of the staff from a former report.

Appointments.

BENNETT, ROBERT A., M.B.Lond., M.R.C.S., L.R.C.P.Lond., District Medical Officer Niger Coast Protectorate, West Africa.
BERRY JAMES, B.S., F.R.C.S., Surgeon to the North London Hospital for Consumption and Diseases of the Chest.
FREEMAN, W. T., M.D.Durh., F.R.C.S., Surgeon in charge of the Department for Diseases of the Skin, Reading Dispensary.
HATFIELD, RONALD, M.B.Lond., L.R.C.P., M.R.C.S., Senior Resident Assistant Medical Officer for the Workhouse, Bradford.
HUTCHINSON, F. A. S., L.R.C.P.Lond., M.R.C.S., Medical Officer for the Dunmow Sanitary District of the Dunmow Union.

JESSOP, W. H. H. M.B.Camb., F.R.C.S.Eng., Honorary Surgeon-Oculist of the Royal Masonic Institution for Girls, London.
LEE, MARY B., L.R.C.P., L.R.C.S.Ed., L.F.P.S.Glasg., Honorary Physician to the Samaritan Hospital for Women, Liverpool.
MCLAREN, J. B., M.B., B.Ch. Irel., Medical Officer for the Salford Workhouse.
MEACHEE, J. H., L.R.C.P.Lond., M.R.C.S., Medical Officer for the No. 2 District of the Bodmin Union.
O'CALLAGHAN, ROBERT THOMAS A., F.R.C.S.Irel., Surgeon and Gynaecologist to the French Hospital and Dispensary, London.
ROSE FRANK, H., L.R.C.P.Lond., M.R.C.S., Anaesthetist to the Bristol Royal Hospital for Sick Children and Women.
SIMPSON, FRANCIS O., L.R.C.P.Lond., M.R.C.S.Eng., Senior Assistant Medical Officer to the County Asylum, Rainhill.
SKERN, W. ST. JOHN, M.B. C.M.Aberd., Medical Superintendent of the Durham County Asylum.
STOOKES, A., M.B., C.M.Edin., L.R.C.S., Assistant Surgeon to the Samaritan Hospital for Women, Liverpool.
TENGE, M., M.D.Brux., L.R.C.P.Lond., M.R.C.S., Medical Officer for the Workhouse, Dunmow.
THOMSON H. CAMPBELL, M.D., M.R.C.P., Officer in charge of the Electrical Department at the Middlesex Hospital.

Vacancies.

Borough Asylum, Portsmouth.—Junior Assistant Medical Officer. Salary commencing at £120 per annum, with board, lodging, and washing.
Carrick-on-Suir Union—Analyst to the Board of Guardians. Applications to the Clerk of the Union. (See advert.)
Corporation of Manchester.—Medical Assistant. Salary £200 per annum. Applications to the Chairman, Sanitary Committee, Public Health Office, Town Hall, Manchester.
County Asylum, Prestwich, Manchester.—Assistant Medical Officer, unmarried. Salary commencing at £100 per annum, with apartments, board, attendance, and washing.
Denbighshire Infirmary, Denbigh.—House Surgeon. Salary £80 per annum, with board, residence, and washing.
East-End Branch of the Children's Hospital, Sheffield.—Out-patient Department.—Lady House Surgeon. Salary £70 per annum, board, lodging, and washing.
Great Yarmouth Hospital.—House Surgeon. Salary £90 per annum, with board and lodging. No alcohol found.
Lunatic Hospital, The Coppice, Nottingham.—Assistant Medical Officer, unmarried. Salary £150 a year, with apartments, board, attendance, and washing.
Oldham Infirmary.—Senior House Surgeon. Salary £85 per annum with board, washing, and residence. Also Locum Tenens. Three guineas per week.
Royal Surrey County Hospital, Guildford. Resident House Surgeon. Salary £80, with board, residence, and laundry.
Roxburgh District Asylum, Melrose.—Assistant Medical Officer. Salary £100 per annum, with furnished apartments, board, washing, and attendance.
Somerset and Bath Lunatic Asylum, Wells, Somerset.—Junior Assistant Medical Officer, unmarried. Salary commencing at £120, with board, attendance and washing.
Staffordshire County Asylum, Stafford. Junior Assistant Medical Officer, unmarried. Salary commencing at £120 per annum, with furnished apartments, board, &c.
Western General Dispensary, Marylebone, London, N.W.—Second House Surgeon, unmarried. Salary £80 a year, with board, and residence and 10s. a month for washing.
Wolverhampton Eye Infirmary.—House Surgeon for six months. Salary £70 per annum, with rooms, board, and washing.

Births.

COLDSTREAM.—On July 20th, at Belford, Northumberland, the wife of George Probyn Coldstream, M.B., C.M., of a son.
FRASER.—On July 22nd, at Epworth, Southsea, the wife of A. Mearns Fraser, M.D., of a daughter.
SECCOMBE.—On July 21st, at 45 Madeley Road, Ealing, the wife of Philip J. A. Seccombe, M.B., of a son.
SMALE.—On July 23rd, at Penweris, Darlington, the wife of John Smale, M.R.C.S., L.R.C.P., of a daughter.

Marriages.

SMITH—THORPE.—On July 20th, at Trinity Church, by the Rev. L. R. Lee, of Mansfield Woodhouse, William Robert Smith, M.D., F.R.C.S., of Beeston, Notts, son of Henry Smith Esq., of Barton Hall, Norfolk, to Ethel, fifth daughter of W. B. Thorpe, Esq., of Linton House, Nottingham.
WARRINGTON—WEEKS.—On July 20th, at St. Martin's-in-the-Fields, London, William Barnett Warrington, M.D., M.R.C.P.Lond., son of John T. Warrington, Esq., J.P., of Liverpool, to Annie Alexandra, youngest daughter of Fleet-Engineer G. J. Weeks, R.N. (Retired) of Forest Hill.

Deaths.

LAURIA.—On July 8th, at Lagos, West Africa, William Benjamin Lauria, M.R.C.S., L.R.C.P., late of Prince of Wales Road, Battersea Park, London.
LEAF.—On July 12th, at Waveney Mansions, Fairhazel Gardens, Hampstead, N.W., Walter Leaf, M.R.C.S., aged 63 years.
NESHAM.—On July 16th, at 12 Ellison Place, Newcastle-on-Tyne, Thomas Cargill Nesham, M.D., Edin. and Durh., M.R.C.S.Eng., L.S.A., aged 57 years.
STEVENSON.—On July 12th, at 105 Gordon Road, Ealing, W., James Stevenson, M.D., late Medical Officer of Health for Paddington, aged 74 years.

Original Communications.

A PRELIMINARY COMMUNICATION ON AFFECTIONS OF THE TEAR-PASSAGES IN NEWLY-BORN CHILDREN.

By SYDNEY STEPHENSON,

Ophthalmic Surgeon to the Evelina and the North-Eastern
Hospitals for Children London, &c.

It is remarkable that ordinary text-books make no reference to a condition that is by no means rare in young babies—namely, a discharge of matter from the eyes resulting from an affection of the lacrymal sac and duct. Moreover, a careful search has failed to bring to light a single recorded English case, although mention of the subject is to be found scattered through the literature of other countries. For the purpose of giving readers a rough idea as to the frequency of this condition, I may state that among 1,538 out-patients seen in the ophthalmic department of the North-Eastern Hospital for Children, Hackney Road, no less than 27, or 1.75 per cent., were affected. Those figures, however, probably understate the frequency of the ailment, since there is reason for believing that many cases get well of their own accord without treatment at hospital or elsewhere.

The following practical remarks are based upon tolerably complete observations carried out upon fifteen of the above patients (nine males and six females).

A baby, generally aged less than six months, is brought with a statement that the eyes have been noticed to discharge either from or shortly after birth. The amount of secretion is often said to vary from day to day without known reason. A history may sometimes be obtained of a discharge from the maternal genitalia, but complaints of "scalding" are uncommon. On examination of the infant, a plug of mucus or muco-pus can be seen lying at the inner canthus or gluing the lashes together. There is no swelling of the lids, and the baby is able to open his eyes freely; the eyeball is not bloodshot; the cornea is clear. Although the palpebral conjunctiva may be rather hyperæmic, yet it never has the thick, red, folded, and villous appearance so characteristic of ophthalmia neonatorum. It is the exception for an obvious swelling to exist in the region of the lacrymal sac—that is to say, at the side of the root of the nose, behind the tendo oculi. More commonly, there is a slight, ill-defined dulness of the region in question. When moderately firm pressure is made with the finger over the internal palpebral ligament, muco-pus exudes from one or another punctum, and often a notable quantity of discharge may in that way be squeezed into the conjunctival sinus. Compression over the sac less frequently gives rise to an escape of muco-pus from the corresponding nostril. Most of the children appear to enjoy excellent health; among my series of fifteen cases, one only suffered from hereditary syphilis. No single patient showed evidences of disease of the

nasal or neighbouring bones. Once a history was got of a similar condition having been present in two other children belonging to the same family. Lastly, in my fifteen cases, the right and the left eye were each affected six times, and both eyes thrice. Nevertheless, it is not rare to find that both eyes were attacked to begin with, and that while one has recovered, with or without treatment, the other has not done so.

If the secretion expressed from the lacrymal sac be examined by means of cover-glass preparations and cultures, it will be found to contain bacteria. For example, complete observations of this kind were made on thirteen of my cases, with positive results in every instance. A single organism was present in six cases, and in the others several. The following microbes were identified:—pneumococci (8); xerosis bacilli (5); staphylococcus pyogenes albus (4); streptococci (3); staphylococcus pyogenes aureus (2); bacillus coli communis (1); pneumobacilli (1); bacillus fœtidus ozænæ (1). In addition to the foregoing, there were found a bacillus like the *B. buccalis* maximus (1); a bacillus of the subtilis group (1); and a large strepto-bacterium (1). Accordingly the organisms most commonly associated with the lacrymal mischief are pneumococcus, xerosis bacillus, and staphylococcus albus. Since the two named last are frequent inhabitants of the normal conjunctival sac, their presence is not likely to be very important.

What is the explanation of these cases? The researches of modern embryology have taught us that the lacrymal sac and duct are formed from a solid rod, which originates by proliferation of the epithelium at the bottom of the lacrymal groove. By liquefaction of its contents, this rod eventually becomes hollow and converted into an epithelium-lined canal. The canaliculi are produced by a bifurcation of the epithelial ridge at the inner canthus. Now, if from any cause delay occurs in the elaboration of the passage, a baby may be born with the lumen of the lacrymal tube blocked with inspissated material, and should the latter become septic, it would furnish a highly favourable medium for the growth of micro-organisms. In this particular respect, the lacrymal passages may be likened to the fœtal vagina, the lumen of which has been found by Dr. J. W. Ballantyne to contain tenacious stuff. An apter comparison would be with the mastitis of babies, where an abscess of the breast may arise from penetration of pyogenic organisms into the epithelial remains that block the ducts of the gland. The lacrymal secretion, as most persons know, is generally absent from the eyes of newly-born babies, and from this fact we might infer that there was little immediate use for the drainage apparatus as represented by the tear-sac and duct. It is possible, indeed, that in every newly-born child the lacrymal duct is still imperfectly developed, and that it fails to become altogether pervious until the advent of tears, say, at the end of the second month. But such a speculation, although interesting, may be quite erroneous. At the same time, we are bound to assume, from the comparative frequency of atresia of the tear passages in babies, that more or less structural defect of the drainage system often does exist at birth. Cases that

recover spontaneously are almost certainly due to a trivial obstacle, such as inspissated mucus; on the other hand, those that persist may be owing mainly to an impermeability of the mucous fold, known as Hasner's valve, which lies at the lower end of the nasal duct. The sources of septic inoculation are naturally many in number, but may be briefly divided into *maternal* and *external*. When discharge exists from the lacrymal sac at birth, infection is tolerably certain to be derived from the maternal passages, and a history of secretion from the genitalia is often forthcoming in such cases. When symptoms are not noticed for several days after birth, the source of infection is likely to proceed from some external agency—as, for example, the baby himself or his surroundings.

Confusion may arise between cases of tear-duct atresia, on the one hand, and of ophthalmia neonatorum, on the other. The two affections, however, agree only in a single point, viz., that discharge is present from the eye. The points of distinction are simple enough. Atresia is generally unilateral, but ophthalmia practically always involves both eyes sooner or later. Atresia is a congenital condition, the effects of which often show themselves at birth; ophthalmia seldom begins until the second or third day of life. In atresia, the palpebral conjunctiva is normal, or, at most, rather hyperæmic; in ophthalmia, on the contrary, it is thick, red, and rugged. Ophthalmia is associated with swelling of the eyelids, and with other signs of inflammation, which are wanting in atresia. Lastly, the secretion in true ophthalmia contains gonococci, whereas in atresia, as already pointed out, it includes several micro-organisms, of which the commonest are pneumococci.

No good effect is likely to follow the mere application of lotions to the conjunctiva, since but little of the fluid employed can reasonably be expected to reach the lacrymal sac. Better results follow careful digital pressure exercised twice a day over the lacrymal sac with a view (a) to squeeze out secretion through the puncta lacrymalia, and (b) to break down the obstruction that is present in the nasal duct. Indeed, most of the cases make a speedy recovery under that simple manœuvre, which succeeds in accordance with the care exercised in carrying it out. When compression fails, we must clear away all obstruction by passing a small probe down the lacrymal duct. Formerly I was in the habit of slitting the inferior canaliculus before probing, but now I content myself with dilating the punctum and canaliculus with a fine, conical instrument set in a handle, which serves not only to stretch the parts in question, but also acts as an efficient probe for the duct. As a rule, a single operation of this kind is enough to cure the case. As some little delicacy is called for to introduce the probe neatly, I always prefer to operate under a general anæsthetic. The same method of treatment generally succeeds in those cases where a definite swelling exists in the region of the lacrymal sac. There is a great risk of setting up a fistula if such a lacrymal collection be lanced from the cutaneous aspect.

CONCLUSIONS.

1. Atresia of the tear-duct appears to be fairly common in newly-born children.
2. It is due to delayed absorption of the material that exists during fetal life in the lacrymal groove or duct.
3. It probably gives rise to symptoms only when the obstructing substance becomes infected with bacteria, of which the pneumococcus is the one most frequently found.
4. It is generally unilateral.
5. It is comparable with the mastitis of babies.

6. It is readily cured by periodic compression of the lacrymal sac; or, if that fail, by introducing a fine probe into the nasal duct.

HERNIA FOLLOWING ABDOMINAL OPERATIONS :

ITS PREVENTION AND CURE. (a)

By A. LAPHORN SMITH, B.A., M.D., M.R.C.S.,
Eng.,

Fellow of the British and American Gynecological Societies; Professor of Clinical Gynecology in Bishop's University; Gynecologist to the Montreal Dispensary; Surgeon-in-Chief of the Samaritan Free Hospital for Women; Surgeon to the Western Hospital, Montreal, Canada.

ALTHOUGH hernia following abdominal operations is, in the writer's opinion, quite preventible, there is no denying the fact that it occurs with sufficient frequency to render it a bugbear more or less to every physician who advises a patient to submit to abdominal section. Rarely does a discussion take place at any of our great society meetings in which laparotomy as a method of cure is recommended, without some speaker, generally on the opposition side, making the objection that the opening of the abdomen may be followed by hernia. And his objection is a very tenable one, for, at the great New York Hospital for the Ruptured and Crippled, the surgeons report an appalling number of patients applying to them in whom this accident has happened after cœliotomy. There may not be so many of these cases in Great Britain and Ireland, but even there one has only to read the journals for a month or two to learn that it is rather a frequent occurrence. When it does happen it gives rise to disturbances, discomforts, and dangers which are sometimes far greater than those of the disease for which the abdominal incision was made. Many of those who came under the writer's care were suffering from strangulation of the omentum or bowel, and were only saved by immediate operation; while others had reflex disturbances of distant organs such as the heart and brain, which, while not dangerous to life, yet caused sufficient misery to require the patients to be constantly under medical treatment. And although, as will be presently shown, the hernia can easily be cured, yet the general welfare of abdominal surgery demands that every precaution should be taken to prevent the necessity of doing a second operation. It may have been the experience of many of you as it has been the writer's, that patients who need an abdominal operation frequently demur and object to the operation simply on the ground that once a woman has had one operation she will have to have a second, and perhaps a third. This erroneous idea has been traced more than once to a single instance of some friend whose primary operation for the removal of one ovary has been followed by a second one for the removal of the other ovary, and a third for the cure of hernia. In fact this has actually happened in the writer's own early experience.

No argument, however, is necessary to prove either the frequency of ventral hernia, or the great desirability of reducing its occurrence to a minimum. Before taking up the question of its prevention, let us for a moment glance at the causes of the accident. Although they are many they may all be included in one category, viz. anything which prevents primary union of the cut surfaces of the middle layer of the abdominal wall, or which allows the newly united surfaces to be drawn apart before the union has been sufficiently well organised to hold the edges together.

(a) Read before the British Gynecological Society, July 12th, 1899.

By the middle layer is meant the recti muscles and the fascia of the linea alba; by the inner layer is meant the peritoneum; and by the outer layer is meant the fat and skin. One cause which is not generally recognised is the drawing of the peritoneum up between the edges of the middle layer, so that they are prevented from approximating. This is caused by taking too much of the peritoneum into the bite of the stitches, so that when they are tightened up the peritoneum is squeezed in between the raw surfaces, thus preventing them from adhering to each other. By taking in only an eighth or a quarter of an inch of peritoneum, this cause could be avoided.

It would probably be better not to include the peritoneum at all, as it unites very quickly simply by falling together.

Another cause, which, however, is well recognised, is failing to take in the bite of the stitches sufficient of the middle layer. This is due to the retraction of the middle layer back between the outer and inner layers. In order to avoid this mishap the skin should be pushed back above and the peritoneum below, so that the muscles will be the most prominent part, instead of the most retracted.

The drainage tube is one of the greatest causes of hernia, because it most effectually prevents primary union of the raw surfaces. Not only does it prevent the surfaces from coming in contact at that point, but it very often infects them, causing suppuration and closure by granulation. Ten years ago the writer drained with a glass tube all pus cases, and those in which there were many adhesions, even if there was no pus; but he abandoned this procedure some three years ago, with the result that no hernia has occurred among his cases since then. If drainage must be used it would be much better to drain by gravity through an opening in Douglas' cul-de-sac, through which a T-shaped rubber tube has been passed, into the aseptic vagina.

But the most common cause of ventral hernia is the custom of removing the stitches much too early. Ten years ago, when the writer succeeded the late Professor Trenholme in the Chair of Gynecology, it was the practice to remove the stitches on the sixth day, and this was the usual custom throughout America. Whether this was also the practice in Great Britain and Ireland at that time the writer is not sure, but judging from the recent book of Dr. Webster, of Montreal, in which he advises the removal of the stitches on the ninth day, and as Dr. Webster was, until recently, Assistant to the Professor of Gynecology at Edinburgh, it would appear that such was the time at which it was customary to remove them in Scotland. Six days, or even nine days, the author of this paper considers far too early a date on which to remove them.

In a paper read before the American Gynecological Society in 1893, the author expressed his views on this point in the following terms:—"When the edges of the abdominal incision are brought together clean and not bruised and with corresponding layers of tissue in exact apposition, we obtain primary union. Under this term we may include all cases of union in which there is no suppuration or granulation, although it does not necessarily follow that there is no exudation of plastic lymph. The ideal union by first intention is of course one in which the cut openings of vessels and the cut fibres of other tissues exactly correspond and unite, but this probably never occurs after an abdominal section. The union is rather due to the exudation of plastic lymph from the opposite surfaces, which forms a gelatinous glue and which eventually becomes organised into white fibrous tissue. We can obtain a good idea of this process by observing what takes place when the tendo-Achillis is cut by the orthopedic surgeon for

the cure of talipes equinus. After the subcutaneous division of the tendon the foot is kept for three days in its former faulty position until the ends of the divided tendon shall have become joined again by the exudation of plastic lymph. When a sufficient quantity of this has exuded, and, while it is still in a soft and stretchable condition, the surgeon gradually brings the foot to a right angle with the leg, when there is perhaps a space of two inches between the cut ends of the tendon, which are united however by this band of soft plastic lymph. The foot is then left in position until this material has become thoroughly organised, when the patient will be found to have the full use of the part. The same thing, I take it, occurs after an abdominal section; and it is owing to the too early removal of the suture while the plastic lymph is still soft and stretchable, and before it has become organised into white fibrous tissue, that we owe the great frequency of ventral hernia. By leaving in the supporting silkworm gut sutures for one month after the operation we can avoid not only the risk of ventral hernia, but we are also saved the anxiety of the incision being torn open during a fit of coughing or other effort, and the intestines escaping out of the abdomen, as has occurred in several recorded cases. If the silkworm gut sutures are left in for a month, as I have done in my last fifteen or eighteen cases, they can do no harm, and this accident is absolutely prevented from happening. Although I am not in a position to state the exact time at which the plastic lymph becomes organised into white fibrous tissue, yet I am in favour of leaving in the sutures at least until the process has had time to be completed. In my last few cases I have been introducing a few buried silkworm gut sutures through the cut edges of the abdominal fascia, which, of course, remain there during the whole of the patient's life, and which, therefore, render the occurrence of ventral hernia impossible. These were introduced after the through-and-through sutures had been placed in position and before the latter were tied." The above was written six years ago, and seems to have had some influence upon the practice of the abdominal surgeons of America, for since then the time for the removal of the sutures has been greatly extended. After six years' further experience the writer may say that he has left in the through-and-through sutures one month in several hundred cases, and with the most satisfactory results. During the last year he has crystallised his procedure into the following formula: "When the abdominal wall is not more than one inch in thickness he employs through-and-through silkworm gut stitches half an inch apart, which he leaves in one month; but when the abdominal wall measures over one and under two inches in thickness, he brings the peritoneum and muscles and fascia together with buried silkworm gut, which remains for ever, and the skin is closed with a subcutaneous silkworm gut stitch, which is removed in ten days. When the abdominal wall is over two inches thick, then, in addition, the fat is brought together with fine catgut after the buried sutures have been tied.

An interesting question is, What becomes of the buried sutures? Are they absorbed? Or do they remain indefinitely as they were first placed? In what percentage of cases do they suppurate? The first question may be surely answered in the negative. The writer has found these stitches while performing laparotomy for the removal of the second ovary more than four years after they were first introduced, and they were as clean and smooth as on the day they were buried, and he believes that they remain indefinitely so. The answer to the third question varies a little, according to the operator and the rigorouslyness of his asepsis. Dr. Noble, of Philadelphia, reported at the meeting of the American Gynecological Society, held at Boston last May, 472 cases

with 10 suppurations, or less than 2 per cent. The writer has had 3 per cent. in nearly 300 cases, consisting of 102 Alexanders, 120 ventrofixations, about 20 ventral and umbilical hernias, and about 60 ordinary abdominal sections.

Would any other material do as well as silkworm gut? There are three alternative materials—namely, silver wire, silk, and chromicised catgut. Silver wire has been used a good deal by Kelly, but it has no advantages over silkworm gut. It is harder, takes longer to tie, and is no easier to disinfect than silkworm gut, and suppuration follows in about the same number of cases. It is possibly more permanent; but then, if silkworm gut lasts four years, of which the writer is positive, that is quite as long as is necessary. If silk could be prepared so as not to suppurate any oftener than silkworm gut, it would have the great advantage of being softer, instead of having hard and sharp ends. In about forty of his own 120 ventrofixations the author attached the uterus to the abdominal wall with Chinese silk which had been boiled and dried, and then dipped in a saturated solution of iodoform in ether. It was then kept in sublimate alcohol until required for use. In only one case out of forty did one of these stitches have to be removed, and that was in a case complicated with pus tubes which burst and infected the incision. The writer thinks that the pores of the silk being filled with minute particles of iodoform the capillarity of the silk is destroyed, and bacteria are also inhibited from growing in it. In passing it might be mentioned that there is nothing so good as a crochet hook for removing a buried stitch, which can be done in a moment, and with very little trouble. Chromicised catgut has a great advantage over all these materials; in that we are also able to make it last as long or as short a time as we like. The author prepares it as follows: The catgut is bought from Keller, of Nassau Street, New York, soaked for a month in ether, then for a month in sublimate alcohol one in five hundred; it is then placed in a watery saturated solution of bichromate of potash for a longer or shorter time. One hour's immersion will make it last a fortnight, two hours a month, one day three months, and so on. The author, however, has been so well satisfied with silkworm gut that he has only a few times used chromicised catgut in the abdominal incision, although he has used it extensively in plastic work, and he is therefore unable to state from actual experience the length of time it requires for the above-mentioned catgut to be absorbed in the abdominal incision.

Another factor in preventing ventral hernia is the keeping of the patients in bed one month after their operations, and the wearing of an abdominal support for one year. Both of these precautions are unnecessary in cases in which the middle layer is closed with permanent sutures; the writer frequently allows these cases to be up in from ten to twenty days and to go home in from twenty to thirty. There is absolutely nothing that the patient could do that could cause the incision to open; and as the sutures are as strong at the end of a year as they were at the beginning there is no need to wear a band at all. This is quite a boon, as many patients complain a good deal of the annoyance of having to wear an abdominal belt. When through-and-through sutures are used and they are left in a month, the period during which it is necessary to keep the patients in bed is very much lessened. One of the writer's patients against his will left his private hospital twelve days after an abdominal section for tubal pregnancy, because her children were stricken with an epidemic disease. This lady was none the worse for her indiscretion, and she walked into his office three weeks later to have the stitches removed. Many others for various reasons

have gone home in two weeks, and come back at the end of thirty days to have their stitches removed. All these patients who have temporary stitches, although they have no need to wear a bandage while the sutures are in, are all carefully enjoined to wear one from the time that they are removed.

If, after what the writer has said, anyone will still persist in removing through-and-through stitches in from five to ten days, then he should be most careful not only to keep his patients in bed for one month and firmly bandaged, but after the stitches are removed the patients should be carefully dieted, so as to keep the intra-abdominal pressure down to a minimum, as hernia can hardly fail to follow the so early removal of the stitches while the uniting material is soft and extensible.

In order to obtain primary union and to avoid stitch-hole abscesses, two things are desirable: first, not to bruise the edges of the incision by putting powerful clamps on every oozing spot until, as the writer has seen, as many as a dozen of them are crushing the tissues. Large vessels should be tied individually with fine catgut, while finer ones should be immediately twisted. Oozing can be stopped by the pressure of very hot sponges.

The silkworm gut should not be tied so tightly as to cut or strangulate the tissues; such force is quite unnecessary; it only requires that the recti muscles which naturally fall together, should be held there by a very moderately tight circle of silkworm gut. The writer has devised two little improvements in technique in order to insure that the margins of the incision will not be distorted by introducing the sutures at unequal distances on the two sides. First, a rubber stamp having a straight line in the centre and a scale on each side marked off into centimetres from one to thirty, is sterilised by heat, and just before the operation and after the abdomen has been washed up it is stamped from the pubis to above the umbilicus in the middle line. When we come to close the incision we have only to introduce the needle at one number on one side and bring it out at the corresponding number on the other side in order to obtain a very accurate approximation. We are greatly facilitated and expedited by hooking up the top of the incision and raising the whole abdominal wall away from the bowels, and, at the same time, keeping them on the stretch; with a sharp Péan needle mounted on a handle we can pass the sutures through almost quicker than an assistant can thread them. From four to six stitches can thus be passed in a minute, a great saving of time on some other methods, and it makes a much neater result. Of course, the Trendelenburg posture is a great help in doing this quick work, because it keeps the bowels out of the way of the needle. How the wound is dressed has little if anything to do with hernia. The writer covers the incision with sterilised boracic acid.

We now come to the cure of ventral hernia. If the hernia is a small one, the ring not measuring as much as an inch in diameter, it may be cured by the following simple method, which the writer employs in small umbilical hernia, namely, by means of a single buried purse-string suture of silkworm gut, passed in the substance of the ring and about a quarter of an inch back from the edge. The latter will have been freshened up by the removal of the sac down to the peritoneal surface of the ring, so that when the single stitch is drawn tight it puckers up the ring until the opening is completely obliterated. It is then tied and the ends cut short. The relaxed skin should not be removed but carefully brought together; it is surprising how its redundancy will disappear in a few days. If the hernia is a long one a different method must be employed. The following case in the writer's practice well serves to

describe the method he employs. The patient was one of the first cases of abdominal section performed in Montreal by one of our oldest operators, but it was in pioneer times and the stitches were removed in six days, with the result that there was an enormous protrusion of the bowels through an opening at least ten inches in length and six inches wide. As the skin was exceedingly thin and the bowels lay almost next to it, an incision one-sixteenth of an inch deep from without inwards would have gone into the intestine. To avoid this a director was introduced through a small nick in the skin above the hernia, and the skin was cut all the way down from within outwards on the director. The intestines were adherent to the whole length of the fascia which had originally united the edges of the incision, but which had stretched out into a thin membrane after the stitches had been removed. As it was impossible to remove this without injuring the bowels, it was cut off the abdominal wall and the intestines were dropped into the abdomen with this part of the abdominal wall attached to them. The edges of the recti muscles were then sought for and found with some difficulty, and the fascia covering them was split up on each side, and twenty-five buried silkworm gut sutures then brought the muscular surfaces, as well as the peritoneum and fascia, in contact, leaving a thick line of union.

The peritoneum of the sac was removed from the skin and the latter was brought together without removing any of its redundancy by a subcutaneous suture. Primary union was obtained throughout without one drop of moisture on the dressing, and the patient has been heard from at intervals during the three years which have since elapsed, and has never had the slightest discomfort from the large number of buried stitches.

To sum up the paper:—

1. Hernia is a frequent complication following abdominal section.

2. When it occurs it prevents other women from undergoing a needed laparotomy.

3. It is quite preventable—

(a) By leaving in the stitches for one month if the woman is thin enough to allow us to use through-and-through sutures; or,

(b) By using non-absorbable buried ligatures when the woman is fat enough to require two layers of sutures. The writer prepares his silkworm gut by placing it in sealed glass tubes and boiling it. A cut with a file is made in the middle, and just when it is required for use the tube is snapped across.

(c) By discarding the abdominal drainage tube, and when drainage is necessary, which it rarely is, draining through the vagina.

(d) By securing accurate coaptation of the cut edges by marking the places where the stitches are to go before the incision is made.

(e) By taking care that no peritoneum is curved up so as to come between the muscle and fascia of opposite sides.

4. Hernia is easily cured in small cases with a single buried silkworm gut purse-string suture; and in larger cases by splitting the edges of the ring until the recti muscles are exposed from top to bottom, and suturing them with buried silkworm gut.

5. Patients with buried silkworm gut stitches do not need to stay in bed more than two weeks, and in some cases less; and they do not need to wear an abdominal belt.

6. Patients with through-and-through silkworm gut stitches left in for a month can, in case of necessity, go home in twelve or fifteen days, and return at the end of four weeks to have their stitches removed. They do not need to wear a support until the stitches are removed, and even then it is

much less necessary than in patients whose stitches have been removed early.

DESCRIPTION OF "TRANSFIXOR." (a)

AS PROPOSED AND USED

By CHARLES WARD, F.R.C.S.I.,

Of Pietermaritzburg, South Africa; Fellow of the British Gynaecological Society; Fellow of the Obstetrical Society of London.

THE "Transfixors" are for use where the surfaces to be brought together are widely separated, as in certain gaping wounds, where the tension on stitches would be great. Also where it is considered possible to do without stitches altogether, by using the transfixor. But it is in abdominal sections where the patient's condition renders it advisable to bring operative procedures to a close as quickly as possible that they are most useful, as the abdominal wound can be closed in a minute, and the anæsthetic stopped, the rest of the proceedings not requiring the use of an anæsthetic.

It will be seen that the "transfixors" are simply Kœberle's hysterectomy pins, modified by having a screw arrangement in the middle. They are intended to be included among the instruments taken to an abdominal section, and if not used entirely in place of stitches, kept in reserve in case the condition of the patient should require their use as explained above.

They should be applied as follows:—

Pass the "Transfixor" about $\frac{1}{4}$ of an inch from the margin of the wound, and go through all the tissues involved in ordinary gaping wounds: except in abdominal cases, in which it should be passed down to Cooper's fascia or subperitoneal tissue, and brought out in a reverse manner on the other side. Unless the peritoneum has been separated from the abdominal parietes it will be found to be in thorough apposition; no stitching is required.

Another "Transfixor" is then inserted about $\frac{1}{4}$ inch from the first, and as many as may be required, usually four, two long (No. 1), two medium (No. 2); the small size (No. 3), being for parts where a long one would be inconvenient. The edges of the wound are then pressed gently together and a layer of (say) double cyanide gauze, laid along it with or without a dusting of iodoform; this must not be too thick. Over this a figure of eight twist with sterilised silk is then passed round each transfixor; the protector is put on, and a light dressing is applied, with pads of gauze under the projecting parts of the transfixors on each side. They may be looked at on the fifth day, and, if necessary, be left on for a fortnight or more without risk.

It may be necessary, if the patient has been very restless, to put in a cutaneous stitch or two at the first dressing, but if care is taken in the application of the transfixors this is unnecessary.

It is claimed for them that:—1. They are quicker in application than stitches; the abdomen can be closed in one minute. 2. They are easily rendered aseptic. 3. If anything they deepen the scar union, rendering it stronger. 4. They leave no stitches or other foreign matter in the abdominal cavity, or peritoneum. 5. They do not constrict vessels or portions of muscles so much as stitches. 6. They allow the anæsthetic to be dis-

(a) Read before the British Gynaecological Society, July 12th, 1899.

continued sooner, and shorten the whole proceedings by ten to fifteen minutes or more. 7. There is no fear of stitch abscess. 8. They hold the wound firmer than stitches. 9. They are not affected by after-vomiting, they cannot cut out. 10. In the event of secondary hæmorrhage the wound can be re-opened rapidly by simply pulling the transfixors out. 11. And the principle of the screw comes in on their withdrawal; by unscrewing the transfixor, and drawing out each end on its own side, no material that has been outside the abdomen, or liable to contamination, passes through the deep tissues, as in releasing stitches; and they are removed with less pain and annoyance to the patients; the pointed end being seized with a needle-holder at the roughened part near the point.

Illustrative Case, February 16th, 1889.—A woman, æt. 40, had a movable mass of rapid growth in the region of pylorus and front of stomach, with malignant cachexia, on abdominal section, the cancer was found to involve nearly the whole stomach. Anæsthetist announced critical condition of patient, proceedings stopped; abdomen closed in one minute in the manner described; and the anæsthetic discontinued. On the fifth day the wound was practically healed; a superficial cutaneous stitch or two were put in where the dressing had got disarranged. Transfixors removed on the twelfth day, wound firm and comfortable on thirty-first day, no sign of bulging whatever.

I saw this woman yesterday, seventy-third day from date of opening abdomen. The disease is invading other organs, but the lump for which the abdomen was opened is much smaller. The scar is very firm.

To have delayed closing the wound in order to stitch it (either in layers or not) would in this case have been dangerous, and would have prolonged the operation quite fifteen minutes; whereas by transfixors the operative proceedings were brought to an end at once.

They are not advisable, or so likely to be effectual, I should think, in cases where drainage is employed. Nor is the idea original except where the screw comes in.

They are made by Messrs. Ferris and Co., Bristol.

A COUNTRY HERBALIST'S CURE FOR THE "KINGS EVIL." (a)

By JOHN KNOTT, M.A., M.D., and Dip. Stat. Med (Univ. Dub.); M.R.C.P.I., M.R.I.A.; &c., &c.

(Continued from page 82.)

DR. JAMES, the contemporary and personal friend of Dr. Samuel Johnson, published his great "Medical Dictionary" in 1745, ten years before the appearance of the work of the great lexicographer. I may mention, in passing, that "Rough Johnson," is known to have contributed very largely to the more purely literary items of this professional Encyclopædia, and that the idea of preparing his own great English Dictionary is said to have arisen while taking part in the work of his friend. James's Dictionary may be taken as a respectable criterion of the knowledge of the period, and of such subjects as that now before us, in the hazy and unsettled style of its science.

"SCROPHULA.—The King's Evil; from *Scrophula*, a swine; because this Animal is said to be much subject to such a Disorder.

"Quincy remarks, that the Gout and the King's Evil agree, in being frequent amongst Persons strong both in Body and Mind, who are hearty Feeders, and on other Accounts well and healthful; in this respect, however, considerably differing, that the Evil generally appears at three, four, or five Years of Age; and dries away by that

State of Manhood that the Gout gives its first Warnings of approach; though neither of these are without some Latitude of Exception. And as the Gout is owing to sharp saline Humours, that are contracted by a particular Way of living, and favoured in their Accumulation by a peculiar Make of the Parts where they settle, upon the Declension of the natural Strength, so this Disease seems owing to a hot, Sharp Humour, propagated a *Semine* from the Parent, in the first Formation discovering itself at an Age, when certain Glands are fitted for its Reception, and disappearing when the digestive Powers have arrived to their greatest Strength.

"That Persons subject to the Evil do early show an uncommon Vivacity of Mind, and Forwardness of Understanding, is a Fact that all have experienced who have been accustomed to such Opportunities of Observation; as, also, that if the Distemper goes on without much Interruption from its natural Course, and dries away about the Age of Manhood, as it commonly does, such Persons are generally strong, and free from Distempers afterwards.

"That such a Humour can be derived from the Parent, is granted, perhaps, in more Instances than where it is really so, and is likely to be yielded by many, more on the Score of a Vulgar Opinion, than for any true Notions of the Manner how such a Thing is possible: It may be, therefore, necessary to form some rational Conceptions hereof, in order to judge what Disorders spring from such an Origin, and which not, because, without some Rules to determine by, Cases may be confounded and mistaken, from some Resemblance in their Appearance which flow from very different Causes.

"To this Purpose, then, I cannot see what we have to do with the Philosophy of the Microscope, so far as it asserts the Semen to be animated before generation, because it seems not in any Manner to affect the Matter under Inquiry; but so far as we get any Knowledge of the sensible and manifest Properties of that small Portion of Matter, from whence we boast the Production of the finest Machines in the Creation, it appears to consist of a very subtle, active Salt, floating in a soft, balsamic Vehicle; whereas, therefore, we can conceive what Consequences to the Economy already formed, may flow from an Excess or Defect in the more active Principles of such a Composition; so may we, by a Parity of Reason, conjecture, what must be the Result of every Deviation from the natural Standard in the same Principle before its Animation in the Matrix. Where, then, this Principle abounds with Heat and Pungency in the masculine Semen, it will not only irritate more frequently and more strongly to Venereal Embraces, but carry with it the same Qualities into the impregnated Ovum; and, without some uncommon Interruption, or Contemperature from opposite Qualities, will increase in the growing Fœtus, in Proportion to its Enlargement, and make a Part of that Constitution to which it gave Being, with the same Afflictions and Properties as it stood possessed of in the generating Semen.

"Hence, it will be no difficult thing to imagine what a Condition the Off-spring of such a Parent must be in: and how, sooner or later, in one or another Part, this primitive Matter may show itself in a very troublesome, if not a very mischievous Manner, as the Circumstances of Life, and Strength of the Constitution encourage or obstruct its Exertion, and the peculiar Configuration of the Glands favour or resist its Accumulation and Lodgment: And though in the Case immediately under Enquiry, it principally shows itself from a little Time after Birth to a State of Manhood, is probable from this Reason, that sooner, it is not in Quantity enough to be discernable, or is hindered from Exertion by the Laxity of the Parts, and Viscidity of Humours, which is always more or less the Case of very young Children; but that when the parts have got some Degree of Firmness, and have digested away the tough Humours, this hot, sharp Matter becomes Sensible to the fine Strainers and Membranes as it passes in the Course of Circulation, and at last fixes upon them so as to occasion Pain, Inflammation, Swelling, and running Sores: But when, again, the

(a) An abstract of this paper was read in the Medical Section of the Royal Academy of Medicine in Ireland on Nov. 18th, 1898.

Constitution takes another Turn, and arrives to its utmost Vigour, the digestive Power become able either to destroy its Pungency by Attrition and Commination, to detach it off by some natural Outlet, most commonly the Glands of the Skin, or to lessen it, so much at least, in Quantity, that it flows with the ordinary Current without sensible Effect, and never afterwards appears, but in giving to the generating Principle the same bad Taint from whence it derived its Existence: And that even frequent Coition and Propagation shall vent and draw off a great deal of this Matter, to the Benefit of the Parent, and Detriment of Posterity, is not only probable, but almost demonstrable; because, during that Time of Life, and in Proportion to such Indulgence, the Parent is always the most free from it, and that during the Travail of a Woman with Child, before subject to such Humours, or any of the like Kind, she shall be entirely free from it then, though if the Issue survives the common Fate of Convulsions, a little more Age seldom fails to discover when such a Mother had her temporary Relief.

"That the Distemper then under Consideration may be thus propagated, is not only out of Question from common experience, but the Manner of it may in some measure be conceived from these Hints, and the Nature of the generating Matter. The same way of Thinking, also will suggest in what Circumstances a Person may fall into this Distemper without having to charge it upon Parents, or the Milk of a tainted Nurse, which, also, may possibly happen, tho', it is believed, very rarely; and that is from a Way of feeding, or any other Condition of living, that gives to the Mass of Humours an uncommon Heat and Sharpness, which in Time shall fix upon the same Parts, inflame and ulcerate them in the same Manner as that derived from a distemper'd Semen.

"The *Scrophula* or *Struma* is a hard glandulous Tumour, usually of the same Colour with the Skin, seated principally on the Sides of the Neck, about the Musculi Mastoidei, behind the Ears, and under the Chin: either more or less moveable, single of the conglobate Kind, or in Clusters of the conglomerate Kind; many Patients having been observed to have them contiguous from the Ear down to the Clavicle.

"Though the principal Seat of this Disease is in the Sides of the Neck, scarcely any Part of the Body is exempted from it; and it affects either Glands, Muscles, Membranes, Tendons, Bones, or the Viscera.

"The Glands are the most remarkable Seat of this Distemper, and whenever the outward Glands appear swelled, those of the Mesentery may be concluded to be so too, the Mesentery being usually the Part first attacked by this Malady.

"If the *Strumæ* have been long ulcerated, and are become sinuous and virulent; and if they lie near one another, they often find a communication to one another, though they appear distinct: In this Case the Lips grow callous, and the Ulcers corrosive, frequently sordid, and the Cure is not to be hoped so long as any one Cystis remains, or the Vessels that feed them; but if the Ulcerations be simple, the Cure is accordingly easy. Those who are seized with *Strumæ* in the Neck, after forty Years of Age, seldom recover, As they personally labour under great Obstructions, whence spring scorbutical Affections, Jaundice, Fainting, Vomiting, Loss of Appetite, sometimes a Dropsy, and sometimes a Cough, in which case they die tabid."

"THE METHOD OF CURE.

"In the Cure three Things are required.

"1. A Regimen of Diet, and the other Non-naturals.

"2. Pharmacy or Internal Prescriptions.

"3. The Applications of Externals, either to discuss, suppurate, or extirpate the Glands.

"With respect to a Regimen of Diet, Regard ought to be had to the Constitution of the Patient, whether it be hot or cold, dry or moist, old or young, robust or delicate. If the Body be cold or moist, we generally suppose a Surfeit preceded, and Crudity to abound; in which Case, Abstinence from Meat and Drink, or at least great Moderation, is requisite. Their Diet ought to be moderately heating and drying, as Mutton, Kid, Rabbit,

Pullet, Chicken, Partridge, Pheasant, Poultry, and the like, and these roasted; avoiding all Aliments which yield a gross phlegmatic Nourishment, such as Water-Fowl, Fish, especially those of Standing Waters, Herbage, Cheese, all smok'd, seasoned or dried Meats. Their Bread ought to be of wheat, well-baked, and their Drink medicated Ale or Beer; Wine also is allowed, and Water utterly forbidden.

"In hot and dry Constitutions tending to a Hectic, we allow a Diet of a more humid Nature, their Meat being boild with Lettice, Spinnage, Purslane, Wood-Sorrel, and the like; to some of these we dare scarce permit the eating of any Flesh, but rather a Milk-Diet, or Asses Milk; though Milk will not be always found agreeable; in which case we prescribe medicated Broths. Pork is, by some, forbidden strumous People.

"Air is a great Help to the Cure, which ought to be mild and gentle, in cold Weather healing and attenuating, and in the hot cooling. Exercise of Body ought to be enjoined, it being necessary to waste Superfluities. Sleeping in the Day is forbidden, unless where the Case is painful, to which it is an Anodyne. The Passions of the Mind ought to be moderated.

"The internal Prescriptions must be qualified according to the Habit of the Body. If it be cold and phlegmatic, abounding with gross viscous Humors, the Prescriptions ought to be heating and attenuating. In plethoric Constitutions, the stronger Cathartics ought to be exhibited, or the milder often repeated. The Purgatives are, the Species *Hiera* with *Agaric*, *Diaturbeth*, *Pulvis Cornachini*, *Pilula Cochiae* à duobus, *Rudii*, *De Hermodactylis*, *Alophanginae*, *Imperiales*, è *Succino*, *Trochisci*, *Alhandal*, *Diagrydium*, *Resina Jalapii*, and *Mercurius Du cis*, and all those Medicines prescribed in the *Lues Venerea*.

"Alteratives are also usefully taken on those Days in which the Patient does not purge. Among these a Decoction of the Woods claims a Pre-eminence; to which are added one or other of the Specifics so called such as the Roots of Fig-wort, Drop-wort, Devil's-bit, Soap-wort, Burdock; the Bark of the Walnut-tree; the Herbs, Rag-wort, Crane's-bill, Herb-Robert, the greater Celandine, Hound's Tongue, white Hore-hound, Fox-glove, and the like.

"In these Decoctions, it is very common to put also a Lump of crude Antimony, of four Ounces or half a Pound Weight, grossly powdered and tied up in a Rag . . .

"Besides these Liquors to be taken as a Diet, there are other Medicines, such as the diaphoretic Antimony, Bezoar Mineral, Ethiops Mineral, and Gum Guaiacum.

"The third Intention is performed by the Application of Externals, 1. To the Tumors which we endeavour to resolve, or suppurate or to extirpate. 2. To the Ulcers which are the Effect either of Suppuration or of Extirpation. In Tumors we shall begin with Emollients and Discutients, though it is no easy Work to resolve these Glands, if we consider the Stubbornness of the Matter, and its being contained within a Cystis; yet in some soft delicate Bodies the milder sort of Glands, which are not too much indurated, frequently resolve. The Emplastrum de *Ranis cum Mercurio* is frequently applied for this End, as also that of the Gums, *Ammoniacum*, *Galbanum*, *Bdellium*, to which crude Mercury may be added as it is in the New Dispensatory. . . . *Zacutus* . . .

says he never used the following Ointment without success: Take of the Root of Great Bryony, plump and round, half a Pound; cut it into small Pieces, and fry it with three Pounds of recent Olive Oil, till they become dry and wasted; strain it, and add Turpentine of Fir, half a Pound; Yellow Wax five Ounces; remove it from the Fire, and make it into a viscid Ointment.

"The Herb Goose-Grass or Clivers, beat up with Lard, and the *Strumæ* therewith anointed, discusses the same, while the distilled Water of the whole Plant lends further Assistance. The Root of Smallage is recommended by Mr Ray for the like Use. *Crilius* as highly extols the Lesser Celandine or Pilewort, whose Roots, he says, are a Kind of Specific in this Disorder.

"Etmuller and Mr. Ray recommend the *Pulvis Cyani*, or Tincture of its Flowers; others, the *Radix Cynoglossi*,

or Root of Hound's Tongue, drinking the Decoction of it, and applying it outwardly in Cataplasms. But the Folium Digitalis, or Leaf of Fox-Glove, pounded and applied to the Strumæ, or the Ointment of its Juice, is highly esteemed by the Botanists. Dr. Bates's Preparation of this Ointment stands thus:—

"Take of May Butter, three Pounds; fresh leaves of Foxglove, bruised, as much as you can mix with the Butter; expose them to the Sun thirty Days; then boil them till the Leaves become curled, and let a strong Expression be made.

"This seems to be the same with that used by Mr. Wiseman which he calls the Valentia Digitalis, having undergone a repeated Infusion of fresh Leaves, by which the same is further impregnated with the Virtues of the Plant. Helmont praises the the spongy or hairy Excrecence, growing out of the Canker-Rose, the Powder being taken to half a Dram mixed with Sugar.

"The Radix Ruscii, or Root of Butcher's Broom, in fine Powder, given to a Dram every morning in White-wine, especially if an equal Proportion of those of Flapendula or Scrophularia be added, and administered in the like Dose, is praised by Etmuller, as is the Rue-leaved Whitlow-Grass by Mr. Boyle. Arnoldus Villanovanus says, that the fresh Root of Scrophularia, eaten for ten Mornings fasting, certainly cures the King's-Evil.

"When the Glands discuss not, but begin to enflame, a Suppuration will be the Consequence; to promote which, let the stronger emollient Suppuratives be applied, as the Roots of White Lillies, Bryony, Marshmallows, Sow-bread, wild Cucumbers, to which may be added fat Figs, and Pigeons Dung; and if the Progress be very slow, for stirring up the sluggish Humour, and rousing its Heat, the Root of Pellitory of Spain, and the seeds of Staves-Acre and Mustard. To promote the Suppuration, it is, also, common to pinch them hard; and some People in the Country thrust a Thorn into them, which excites Inflammation, and disposes them to suppurate. Care must be taken to endeavour a perfect Concoction; for if they are opened while any Part of the Gland is hard, it will encrease, and occasion a Necessity of eradicating it, or of leaving the Cure imperfect."

The writer proceeds to discuss the processes of incision, extirpation, subsequent dressings, &c., &c. And towards the end of a long dissertation on the various special forms of strumous disease, he returns to the neck and indicates a confusion of ideas between scrofula and goitre, which does not seem to have prevailed so much in even less enlightened times. "Those Tumors are called strumous or scrophulous, which appear externally, on the anterior and lateral Parts of the Neck. Of these Tumors there are different Species; some are small, some of a moderate size, and some surprisingly large; some are soft, others hard; some are moveable, others immovable; some are favourable, others malignant. Scrophulous Tumours arise in indurated glands of the Neck; sometimes in the small moveable glands; sometimes in the superior and inferior salival Glands, and sometimes in the Thyroid Glands, which last are by some particularly called *Scrophulæ*, or the King's-Evil; and by the French, *Ecroutelles*."

(To be continued.)

The Nursing Problem.

NURSES OF THE LATEST FASHION.

A.D. 1899.

PROFESSIONAL EXPERIENCES IN SHORT STORIES.

By FREDERICK JAMES GANT, F.R.C.S.,

Consulting Surgeon to the Royal Free Hospital.

SATAN IN PETTICOATS (continued).

SUDDENLY a change came over the spirit of Lucretia's devoted service, and in the name of Him—

Incredible as it may appear that one whose professed

qualifications seemed to be already verified by her nursing attendance, she should, under a week, give practical proof of her own incompetency; moreover, nurse frankly protested her own unfitness, terminated the trial, and must leave that day—that hour, at whatever inconvenience and wrongful loss to the patient. But, of course, "I claim my wages for the month." In vain, the poor helpless "dear old lady" implored her all-in-all not to desert her; for, "you know that other woman, kind as she is, can do little, or nothing, as you can; she cannot turn me in bed, not lift me out of it into my chair; and oh, the long nights, without you. Remember, I don't terminate the month's trial." With a deaf ear to piteous entreaties, Lucretia still protested her own unfitness—must go at once—and with the month's wages.

When the news of lovely Lucretia's immediate departure, &c., was communicated to the old husband, he, quite hitherto unaccustomed to such domestic matters, thought he understood dear nurse's case. She was one of the itinerant, migrating black birds of passage, who flit from place to place, quitting each within a few days, and demanding, extorting from their helpless, world-excluded victims, a month's salary, for, say, three days' service, worthless work, the servitor being quite incompetent to undertake any duty, such as answers to the advertisements, they are ever scanning for an eligible "find." A very easy mode of making an income, without any capital of ability, industry, or character.

But Lucretia must go; very sorry to quit such a happy place; but go, she must really, and with the month's wages. Lady U—— had not paid her wages, on quitting her ladyship's service; nor had that same "unjust, irreligious lady" kindly forwarded to her the purse she had forgotten in her hasty departure. Consistently with this explanation of Nurse Lucretia's position, it would have seemed more reasonable that she should have remained in her present situation, instead of throwing herself out of place, and forfeiting her wages by terminating her engagement; certainly, however, in her unfortunate financial circumstances, Lucretia's absolute penury would explain and excuse her otherwise pitiful dishonesty in not having yet paid the shilling cab-fare borrowed of Nurse 2, as the debtor had neither received wages owing to her, nor had she come into her property by book post.

Practised as I am in thinking the thoughts of other people, women's thoughts especially, I own that the movements of Lucretia's mind puzzled me, so that I could not interpret to the old husband the real motive for nurse's sudden decision.

She demanded a month's wages for under a week's service, determined by her own professed inability to continue the duties of her engagement. "She could," she said, "summon either the (paralysed) patient or her husband, to the police-court, and thus prove her rights—as by agreement, and get her lawful wage"; this threat being accompanied with a fierceness of utterance by the playful little mouth, a resonant tone of the silvery voice, and a gleaming fixed glare of the gazelle eyes, utterly unbecoming the placid, gentle, loving woman, up-to-date.

Unfortunately, the poor old wife's condition rendered her totally unable to appear as witness in a police court; and as she alone had made the (verbal) engagement with Lucretia, her astute threat was as idle as it was heartless.

But "No," she went on to say, "she knew police-courts very well, and she knew the law; her father was a barrister, only she was not on terms with him; it would not become her social position for her to appear in court, as the case would be published in all the morning papers, and she would be identified in connection with a petty claim for wages, as nurse-attendant, when it might not be known to a wide circle of friends that circumstances had compelled her to adopt a calling below her birth."

Accordingly; Lucretia was quite willing to remain, but in the service of the old husband, as cook. "She had—she told him—gained considerable experience in the culinary art, especially for invalids." "This offer she made, knowing that the dear patient had already engaged another, and far more capable, nurse-attendant, who would arrive in the evening; and as she understood that the cook was having a holiday from that day, she would

gladly take her place—as a matter of convenience—in the household arrangements.”

To the regions below Lucretia descended, there to exercise her culinary art, in preparing such delicacies by her own little hands as might as much please the palate, and suit the stomach of the invalid, as in her nursing capacity she had ministered to other bodily wants, and had fed the soul with good things. The old husband's appetite, not so fickle, would be more readily satisfied.

The most astutely vicious people are often the most blindly stupid, and are wont to give evidence against themselves. It was so with Lucretia. She readily entered into an agreement—in writing to the effect—that she surrendered her claim for a month's wages as nurse-attendant. She agreed to remain in service—as cook—for her own convenience; and that *one week's* such service, at the same rate of wages, would satisfy her previous demands for a month's remuneration.

At first, Nurse Lucretia's cooking fully justified her claims. Excellent beef tea, and other products of invalid cooking, were served up to the old lady: while the old gentleman, himself a great sufferer, fed, as it were, by manna from heaven, began to feel the renewal of life in the hands of the angel-cook, breathing a prayer in return that old Mrs. Clipper might be induced to extend her holiday *sine die*.

About the third day of this course of nutriment, the wife, who during more than a year's bed-room incarceration had slowly regained such general health as made her life tolerable, although still afflicted with infantile helplessness, began to throw out symptoms of internal distress. Persistent diarrhoea, a burning throat, and thirst, bespoke continued irritation of that tract within the body, through which passed the products of the culinary art, with alarming rapidity. What the irritant might be which thus seemed to convert the stomach into a saucepan for boiling its own contents, while the bowels were the sink for cleaning and washing out, ere the receptacle was used again, might have been a mystery to any other old man, beholding his poor old wife in writhing agony at times, rallying again when the invisible enemy was withdrawn, and so on. But, in the evening, when the first piteous scene in this tragedy was enacted, fortunately the husband, having a bed-room ticket of admission, and being a judge of blacking upon the fair skin of womankind, had studied the cook-specimen, who under cover of nurse-attendant had got into his wife's service.

Sitting in the dining-room, after witnessing his wife's agony, the old man fell into a trance, with his eyes open and conscious of what he saw, otherwise in a state of abstraction. Suddenly the door opened, and a lurid vision entered, with outstretched arm, the withered bony hand and forefinger of another old man pointed at the seeming sleeper; spellbound, the visited could not rise from the couch on which he reclined. The visitor with a tone of voice, more in sorrow than in anger, said—“Beware of your nurse-cook; beware of the would-be *murderess* for money—beware of the bigamist—of the widow, as she is not—the liar—the religious hypocrite—the prostitute—the *swindle*—the common thief!!!”

The old husband, awakening as from the abyss of hell, rose, tottering, and rang the bell. The vision vanished. But cook, thinking it might be some special invocation of her culinary art for dinner on the morrow, answered the summons.

“On this occasion”—the old husband said, with resonant voice—“It is I—your master—who orders you to quit this house immediately.” “You are a woman with a past,” said he, as their eyes met. “Thank you, yes,” replied the satanic nurse, Lucretia, “I own I have a most romantic past for a young lone woman if all were known.”

But I know something more of you. “Do you.” “You are a woman without a future—except a prison—or death.” “Thank you; do you, know *that*.” Lucretia never looked more self-possessed, calm, gentle, modest, kindly-cruel. But Robinson, the maid, found her in the hall, hanging over the stair-rail in a fainting condition.

To forthwith get rid of nurse-cook—thus convicted—was yet no easy matter. She not only had the effron-

tery to reclaim a month's wages by the wife's verbal agreement with her—as Nurse, which, if valid for three days service terminated by herself, she had afterwards cancelled by her willing signature to the terms of the written agreement for one week as cook; she now claimed a month's wages in that capacity; two months, in all for both services. She “knew the law”; and “she would certainly lay her case before the police magistrate, Mr. P———n, who would protect her rights.” “No”—on second thought—“she would not.”

But why—in addition to her vocation as swindler, should Nurse Lucretia have been cook-poisoner in this case? Money moved her influence over the mind of an old lady who is exceedingly susceptible to kindness, unsuspecting in her own simple honesty—who possesses property in personal estate, at her own disposal by Will.

Now, the mysterious reason for her desire, and determination to suddenly relinquish her nursing attendance on her victim, was evidently explained by the circumstance that cook's holiday gave Lucretia the opportunity for carrying out her diabolical design. Her greed for money had impelled her to practice the old trick of demanding wages not her due, but she at once relinquished her fraudulent claim in view of her far longer expectations under the Will, in the event of a successful issue to her cooking service.

Lucretia's second thought took her out of the house without further reconsideration.

After her departure, the “dear old lady”-patient sent a piece of note-paper to her husband in the dining-room; “That woman has carried away all she could rob me of, without detection.”

Nurse Lucretia's Immediate Antecedents.

Prior to her appearance in Catchemalivo Square I have received authentic information, written and verbal, respecting Nurse Lucretia's immediate antecedents.

When residing with Lady U——, as nurse, she stole everything she possibly could remove, without discovery at the time, damaging and destroying much valuable property in articles of vertu; notably one vase, of rare and costly porcelain, cherished as a gift to Lady U—— on the occasion of her marriage. The household servants became instinctively alarmed by nurse's conduct, as ominous whisperings came to their ears; they locked her bed-room every night, lest she might visit them during the hours of darkness. At last, she quitted this situation, being compelled to leave without warning.

In her previous situation, as nurse in sole charge of an only child—girl, winsome and affectionate, she beat and otherwise ill-used the nursing, who needed no correction of its endearing charms. She always locked the door of the happy, playful, unprotected little lady, so as not to be interrupted in her nurse duties, or interfered with by any servant. The door being unsecured on one such occasion, the mother, with perhaps her maternal apprehension aroused, entered the room, just in time to see nurse in the act of administering a spoonful of something from a saucer containing a reddish fluid. The poor little thing fell asleep, and remained so long insensible to mother's voice and awakening cries, that it was feared she lay asleep to wake no more.

Whether this well-nigh fatal deed was done by the hand of a murderess, with some secret motive and purpose, or whether an overdose of medicine was administered by the hand of an ignorant, “untrained,” and “uncertificated” nurse, is known only to Him who seeth in secret.

Certain, however, was the sequel—that Lucretia forthwith surrendered her charge of the little patient, and, without the least protest, consented to leave the house, but demanding (her old claim) a month's wages. Threatening the summons from a Police-court, and the assistance of her legal friend (with whom the reader is acquainted), at once silenced the mother's demurrer; as a nervous lady, she dreaded her name appearing in the papers, and which would be “equally distressing to nurse, a lady born, and well known to the magistrate,” the case was settled out of Court, “the mother of the hapless innocent agreeing to pay nurse's lodgings until she could recommence duty in another situation.”

Thus, this head-nurse of the latest fashion disappear from our view.

Clinical Records.

CANCER HOSPITAL.

Cases under the care of Mr. F. BOWREMAN
JESSETT, F.R.C.S.,

Surgeon to the Cancer Hospital, Brompton.

I.—Case of Large Dermoid Ovarian Cyst removed from a Woman, æt 72—Recovery.

A. M., æt. 72, was admitted into the Cancer Hospital on November 8th, 1898, suffering from a very large ovarian cyst. Her abdomen has increased in size rapidly for the last three years. At the birth of her last child, thirty-five years ago, she remembers the doctor telling her she had a tumour, and fifteen years ago she was advised to have an examination but declined. She has had eleven children.

Present Condition.—A healthy-looking woman; has lost flesh of late. Abdomen enormously distended, bulging abruptly just below the ribs, of oval shape, with long axis running obliquely downwards and to the left. The abdomen is dull over whole area, excepting just below sternum.

November 15th.—I opened the abdomen with a small incision in the middle line below the umbilicus. The cyst presented, and was found to be generally free from adhesions. Trocar was inserted but no fluid escaped, on withdrawing the trocar a quantity of small greyish-brown masses, the size of pearl barley, escaped mixed with thin brownish fluid. There was a large mass containing nucleus of matted hair. The cyst when emptied was drawn out of the wound. There were a few adhesions to the omentum, which were readily torn through, a long pedicle was ligatured and dropped back. The patient made an excellent recovery from the operation. Some time later she had a slight convulsion accompanied by right hemiplegia. Her condition now is much the same, having never recovered from the attack.

II.—Case of Carcinoma of the Cervix Uteri Complicated with Pregnancy—Vaginal Hysterectomy—Recovery.

E. P., æt. 30, married, three children. Patient's attention was drawn to a dull pain in hypogastrium at Christmas, 1898, since which time she has had continuous discharge accompanied with hæmorrhage. The discharge very offensive. She was admitted into the Cancer Hospital on February 22nd, 1899.

She is a healthy-looking woman, but complains of pain in hypogastrium. On examination of abdomen tenderness is elicited. Per vaginam the os and cervix are found to be deeply ulcerated, the vaginal walls, however, are not invaded. The uterus is quite mobile. Examination causes hæmorrhage.

February 28th.—Vaginal hysterectomy was performed. Uterus and ovarian vessels were clamped by Doyen's forceps. Forceps left on for thirty-six hours before removal. The vagina was packed lightly with iodoform gauze, which was not removed until the fifth day.

The patient made an excellent recovery.

On opening up the uterus, which was enlarged, it was found to contain a foetus of about two months' gestation.

III.—Case of Fibro-Myoma of Uterus taking on Malignant Action—Panhysterectomy—Recovery.

Miss R.—, æt. 56, brought to me by Mrs. Marshall, M.D., with the following history.—No family history of cancer. Menopause—in 1895; late in the year she consulted Dr. Macan, of Dublin, on account of loss of blood per vaginam. On examination some fibroids were discovered. The bleeding however continued, and she consulted Dr. Cullingworth, who considered the fibroids were the cause of the hæmorrhage. In 1896 she saw Sir John Williams and Dr. Cullingworth in consultation, they at that time could find no reason to suspect malignancy. She spent the winter of 1896 at the Riviera, but the hæmorrhage still continued. On her return to England she again sought Sir J. Williams' advice who then suspected there might be some inter-uterine mischief.

On June 2nd, 1897, she was placed under ether and

the uterine canal dilated, and Sir John Williams removed some growth which proved to be malignant.

It was thought that the disease had invaded the broad ligament, and that it was not a suitable case for operative interference.

She consulted me on October 28th, and with Mrs. Marshall, M.D., we placed the patient under an anæsthetic and examined her. The uterus was found to contain several fibroids, and there was a badly smelling discharge from the os. The vagina was quite free from disease, and the os and cervix also felt healthy. The right broad ligament felt somewhat thickened. On examination per rectum this thickening was evidently due to the presence of fibroids; the whole uterus appeared to be covered with bosses.

The uterus was quite movable, but there appeared to be some adhesion in Douglas's pouch.

The conditions found, in my opinion, quite warranted my advising an operation for the removal of the diseased organs, an opinion in which Mrs. Marshall agreed. Owing to the size of the uterus, I thought it wiser to remove it by the abdominal route, and on Nov. 7th, with the assistance of Mrs. Marshall, Mr. Ryall, and Mr. Richardson, Dr. English giving the anæsthetic, I performed panhysterectomy in the usual manner. There were some firm adhesions in Douglas's pouch, otherwise no trouble was experienced. The patient made an even recovery, and a month ago when I saw her she was quite well.

IV.—Case of Malignant Disease of the Fundus of the Uterus—Vaginal Hysterectomy—Recovery.

Mrs. R., æt. 43, three children, youngest ten years, since which time she has suffered a good deal from "bearing down" pains, in consequence of which Dr. Campbell Pope, her medical man, took her to Sir John Williams in May, 1890. It was not until May, 1897, that these pains increasing she again saw Sir J. Williams. In September, 1897, excessive menstruation commenced lasting for six weeks at a time, stopping only for three or four days then commencing again. This state of things continued until April, 1899. On April 12, Sir J. Williams dilated the uterine canal, and curetted the uterine cavity. The debris on being examined were pronounced to be malignant.

On June 20th Dr. Campbell Pope asked me to see the patient with him, he administered an anæsthetic, and I made a thorough examination, the uterus was very large and a sanguineous discharge was escaping from the os. The broad ligaments were free, and there was no ulceration of the os or vaginal walls. The uterus was fairly movable. On introducing a sound it passed readily for 3½ inches and caused bleeding.

I advised vaginal hysterectomy, which was agreed to, and I with, the assistance of Dr. Campbell Pope, and Mr. Ryall, performed the operation on June 27th.

There was some difficulty owing to strong adhesions in Douglas's pouch and the size of the uterus in delivering it, this was overcome, however, by splitting the anterior wall of the uterus up and pulling it down. The broad ligaments were ligatured. There was, however, some hæmorrhage from a small vessel somewhat high up. As there was some difficulty in ligaturing this I clamped it with a pair of pressure forceps. The patient made a slow recovery and was troubled with some little urinary leakage, which was due probably to the ureter being nipped by the forceps, this it is hoped will disappear as the wound cicatrises.

Transactions of Societies.

BRITISH GYNÆCOLOGICAL SOCIETY.

MEETING HELD THURSDAY, JULY 13TH, 1899.

Dr. MACNAUGHTON-JONES, President, in the chair.

MR. BOWREMAN JESSETT showed: 1. A case of carcinoma of the cervix uteri complicated with pregnancy. 2. A case of malignant disease of the fundus of the uterus. 3. A case of fibro-mycma of the uterus.

taking on malignant action. 4. A large dermoid ovarian cyst removed from a woman, *æt.* 72. Notes of which will be found under "Clinical Records."

Dr. HEYWOOD SMITH said that it was very interesting to trace the transition in these cases between fibroid tumours and malignant disease. He asked whether a fibroid uterus was more likely to take on malignant action than one that was not fibroid.

Dr. SNOW thought that malignant disease of the body of the uterus could be treated with success much later than when the disease affected the cervix; because in the former case the growth was encysted, whilst in the latter the lymphatics were involved far earlier. There were two ways in which myoma and malignant disease might be related. (a) The association might be merely accidental. (b) Malignancy might follow myoma, owing to the predisposition brought about by congestion. This was not a true passing of myoma into malignant disease, but the course of events was as follows: First, owing to the hyperplasia of the uterine muscle this passed into an embryonic condition, and this condition in turn merged into sarcoma. It was only in this way that the one growth could pass into the other.

The PRESIDENT said that the course of opinion tended in the direction that a myoma could sometimes become malignant, *i.e.*, sarcomatous. He had shown a case some time ago at the Society, and had seen another case since, in which myoma and carcinoma co-existed; but in both cases it was difficult to say whether the connection was accidental, or whether the carcinoma was an invasion of the myoma. In cases of large uterus where they were uncertain whether they had to do with hyperplasia or with malignancy, they should be prepared to warn the patient that the uterus might have to be removed. These were just the cases in which a diagnosis could sometimes be made early.

Mr. JESSETT, in reply, said that his main object was to lay stress on the importance of early diagnosis. He had no doubt that for carcinoma of the fundus vaginal hysterectomy was a most successful operation. He had now many cases in which this had been done for some time, and the patients had remained quite well. Cases in which the disease affected the cervix and spread down to the external os were the most unfavourable, for then the glands were involved much earlier. He believed that the prognosis was much better in old patients, say, after 50, than it was in young women. The same remark applied to malignant disease of the breast.

Dr. GEORGE KEITH showed, for Mr. Skene Keith, the ovaries from a case in which they were removed for a bleeding fibroid, and a diseased appendix from the same case. The patient, *æt.* 27, had had pain in both sides and in the back since she was eighteen, for which she had had a great deal of local treatment. Four years ago she had an acute attack of appendicitis. Examination showed both ovaries prolapsed, with a retroversion of the uterus. At the operation a fortnight ago the ovaries were found prolapsed and adherent; and the appendix was very long and adherent to the abdominal wall. The interest in the case was the condition of the appendix combined with the diseased ovaries.

Mr. Targett had made an examination and reported that the chief features of the specimens were:—1. Closed ostium and moderate dilatation of the tube. 2. The presence of blood distending the tube. 3. Thickened prominent rugæ of mucous membrane of the tube, which were seen embedded in the clot. 4. Microscopical examination showed acute tuberculous infiltration of this mucous membrane, which was evidently a primary lesion as there was no tubercle on the serous surface.

The PRESIDENT showed a case of primary tuberculosis of the Fallopian tubes, associated with hæmatosalpinx.

Dr. HEYWOOD SMITH had had a similar case some years ago, both sides being affected. He removed both appendages, and after the operation the patient gained considerably in weight.

Dr. POWELL asked whether the lungs had been examined in this case? He had lately seen a case which was thought to be one of primary tuberculosis of the larynx; but later on tuberculosis was found in the lungs. He believed that most cases were primary in the lungs.

Dr. ARTHUR GILES asked whether in the President's case the tubal condition was associated with hydro-peritoneum? Four years ago he saw a patient, *æt.* 16, with a cystic pelvic swelling, which was diagnosed as localised tuberculous peritonitis. On opening the abdomen this was found to be the case, but in addition there was tuberculosis of both Fallopian tubes, which appeared to have been the primary seat of the mischief. The lungs had been examined and found healthy. He removed the tubes and drained the pelvis; and the patient recovered and improved greatly in general health.

The PRESIDENT, in reply, said that an interesting feature of the case was this, that the ovaries had been carefully examined, and there had been found no extension of the disease, either to the ovaries or to the uterus. The latter was small and fiddle-shaped, thus accounting for her sterility.

A paper by Mr. Charles Ward, Pietermaritzburg, was read, on "Transfixors, for Securing the Abdominal Wound." The Secretary also read, in the author's unavoidable absence, a paper by Dr. A. Lapthorn Smith, Montreal, on "The prevention and Cure of Hernia after Abdominal Section." The papers will be found in another column.

In the discussion that followed,

Dr. PURCELL remarked that stitches remained buried and unchanged for a long time. Thus he had done a perineorrhaphy with buried stitches which had remained for twelve months, and which he had then removed, as they were giving pain. They were unaltered.

Mr. BOWREMAN JESSETT thought it would be interesting to know what 167 ventrofixations were done for in a few years. It seemed a very large number. In England he thought that two weeks was considered a long enough time to leave stitches in after abdominal section. He had used silk for ventrofixation, but had always regretted it, for it so often gave rise to abscess. For the removal of sutures he had not found anything so handy as a crochet hook.

Mr. FURNEAUX JORDAN observed that probably no two surgeons sewed up the abdominal wall in the same way. The great preventive of hernia was primary union, and the secret of primary union was asepsis. The length of time stitches were left in was not of great importance. As regards suture material, he would not like to leave silkworm gut buried, since the hard ends were apt to hurt; boiled silk answered very well as long as it was aseptic. In most cases he used through-and-through sutures of silkworm gut.

Dr. HEYWOOD SMITH said that since the method of suturing in three layers had been adopted there was very little fear of hernia. Further, the wound healed better if the incision were made through the recti instead of through the linea alba. For the middle layer he thought that interrupted sutures were better than the continuous.

The PRESIDENT did not think that on this side of the water they had an "appalling number" of hernias following abdominal section. He had had only one case of hernia, and that was due to the patient herself, who was insane; she did what she could to open the wound. He took exception to the statement that this kind of hernia was easily cured. He had no doubt that drainage was responsible for many of the cases of hernia that used to occur. His own practice was to use three layers of interrupted sutures. He would not like to bury silkworm gut nor silver wire as advocated by Howard Kelly. The principal thing was to get primary union of the fascia and muscle. He concluded by expressing the indebtedness of the Society to Dr. Lapthorn Smith for this interesting paper which he had sent them from Montreal.

THE LATE MR. LAWSON TAIT.

The PRESIDENT dwelt on the great loss the Society had sustained by the death of Mr. Lawson Tait, one of their honorary Fellows. Their loss was shared by Great Britain and Ireland, as well as by gynaecology all over the world, for Mr. Tait was one of the most prominent representatives of this branch of surgery of his time, an original thinker, and a bold and successful surgeon. At a recent meeting of the Council a vote of condolence with Mrs. Tait on their common loss had been unani-

mously passed, and he felt sure that the Council had but expressed the sentiment of every Fellow of the Society.

The remarks of the President were cordially and respectfully endorsed by the meeting, which then separated.

Special Article.

TUBERCULOSIS OF THE BONES, JOINTS, AND GLANDS, AND ITS TREATMENT BY THE OPEN-AIR METHOD AT THE SEASIDE (INSTITUT VERNEUIL, LA BAULE-LOIRE INFERIEURE).

In discussing the treatment of tuberculosis it is necessary at the outset to distinguish clearly between pulmonary tuberculosis, the only form of the disease with which the public in general are as yet familiar, and the various localised manifestations of tuberculous infection which are so frequently met with in bones, joints, and lymphatic glands. Although all forms of the disease are, roughly speaking, answerable to the same method of constitutional treatment it is necessary in practice to make a distinction, because the risk of infection which is inseparable from the pulmonary form does not obtain in the more strictly localised lesions met with in the bones, in joints, and especially in the lymphatic glands. It follows that the treatment of the latter requires to be carried out in separate establishments, specially organised to deal with this particular class of cases.

In the course of a recent voyage in France it was our good fortune to have been afforded an opportunity of visiting a remarkable institution in Southern Brittany where the treatment of delicate children of both sexes has for many years past been carried out on a large scale by what was described as the open air marine treatment with results which appear of sufficient interest to merit publicity in this country where public opinion is fully alive to the necessity of measures having for object the cure of the afflicted and the prevention of infection.

Some thirteen years ago a local philanthropist purchased a large plot of land surrounded by water and isolated from the mainland at high tide, situated near Le Croisie (Loire Inferieure) for the purpose of installing a sanatorium for the reception and treatment of the young of both sexes suffering from tuberculous disease other than phthisis. The buildings, all on the ground floor, are built on the principle of securing an ample supply of fresh sea air, and are provided with every modern sanitary appliances. Surrounded on all sides by extensive tracts of sandy soil and bathed by invigorating breezes from the ocean, the inmates pass their lives virtually in the open air. Caressed by the balmy and uncontaminated air, enveloped by direct sunlight, and suitably nourished, the miserable and degenerate products of town life, incapacitated for childhood's pleasures by the ravages of tuberculous disease, find in the Pen-Bron Marine Hospital a *milieu* admirably calculated to stimulate their inherent vitality, and to enable them to react against the further spread of the disease.

The credit for the success which has attended the administration of the Pen-Bron Hospital is mainly due to Dr. Jan-Karguistel, the medical superintendent, who has from its foundation displayed a scientific and affectionate interest in its management. Thanks to his activity the hospital was formally recognised by the State as of public utility in 1893, and it receives subventions from a large number of communes and municipalities, who in turn send their sick to the hospital for treatment. The conditions of admission are very strict from a medical point of view, the benefit of the institution being restricted to those whose condition is such as to justify the hope of eventual cure, or at any rate of material improvement, by the Marine treatment. Although the object of the founders was exclusively the treatment of the victims of localised tuberculosis, the benefit of the treatment is in exceptional circumstances accorded to debile and convalescent children on the

express condition that they do not present lesions capable of proving injurious to their fellows.

The Pen-Bron Hospital at present accommodates between three or four hundred children of both sexes. There is no limit of age as regards the girls, but males are not admitted above the age of 15. In the course of our inspection we were shown examples of pretty well every variety of local tuberculous lesions—tuberculosis of various bones and joints, tuberculous ulcers, involving the bones of the skull, the antrum, the mastoid, the nose, &c., but the predominant feature was tuberculosis of the lymphatic glands, especially of the neck, suppurating and non-suppurating. Most of the incoming patients arrive in an advanced stage of cachexia, and it is impossible not to be impressed with the promptness with which these little sufferers had regained strength, colour, and gaiety under the influence of these surroundings. The treatment comprises not only an existence under peculiarly favourable hygienic and dietetic conditions, but care is taken to exercise the minds as well as the bodies of the inmates. Under the sympathetic but firm rule of the sisters, who have devoted themselves to the task, every hour of the day has its allotted occupation, educational, religious and recreative.

There could be no more touching spectacle than that of the children basking in the shade of the trees, their eyes beaming with the sensation of recovered vitality, smiling, with faces expressive of affection and gratitude, to the sisters and to the doctor who knew each one of his flock by his or her name. The pallor and the hectic flush in all save the most recent arrivals had given place to the tawny glow of health, and their placid happy physiognomies testified to the *joie de vivre*.

The average duration of treatment is from twelve to eighteen months. There is an operating theatre fitted up in a way which would do credit to a London hospital, for the surgical treatment of cases requiring operative measures. The wards are spacious, with large windows on both sides, with ample space between the beds, and scrupulously clean throughout. In the space at our disposal it is impossible to do justice to the admirable organisation of the institution. We cannot do more than sketch the main outline of a scheme which enables children capable of deriving benefit from Nature's own treatment, to be restored to health at a cost not exceeding 1fr. 80 (rather less than 1s. 6d.) a day. The benefits of the Pen-Bron Hospital, as we have explained, are restricted to the children of the poorer classes, the cost of maintenance being defrayed by the local authorities by whom they are sent. The unquestionable and excellent results of the treatment during the last thirteen years have attracted public attention, and a movement has been set on foot to extend these benefits to the children of persons of a higher social standing who would be willing to pay for similar privileges on a scale commensurate with the greater comfort and conveniences. This movement has recently led to the construction of a building at La Baule, a few miles distant from the Pen-Bron Hospital, situated on the shore of a bay and surrounded by extensive pine woods forming part of the grounds. This is known as the Institut Verneuil.

The Institut Verneuil is to all intents and purposes a Pen-Bron institution on a more luxurious scale. Built of granite on a rising plot of ground facing the ocean, it is at once an architectural monument and an ideal sanatorium. The main block is reserved for the reception of young patients, but isolated villas are scattered through the extensive pine-clad grounds for the reception of adults. To the visitor in search of rest and recreation, as well as to the invalid requiring a thorough course of treatment, the Institut Verneuil, which is under the patronage of the most eminent French medical authorities, commends itself as a summer and winter residence by its complete organisation and unique natural advantages. A special department is provided for children of both sexes, with this unique advantage, that those of delicate health are enabled to pursue their education in company with others of their own age, while deriving lasting benefit from skilled treatment and a favourable climate. The establishment, indeed, affords

the freedom and comforts of home under circumstances which, we believe, cannot be rivalled elsewhere.

The locality is celebrated for its salubrious and restorative climate owing to its geological conformation, its exceptional situation and the influence of the Gulf stream which bathes its shores, it possesses in all seasons that uniformity of temperature so essential to the recuperation of the debile and convalescent. Eucalyptus, pomegranate, and similar trees grow freely in the open air, a fact which sufficiently testifies to the mildness of the winter.

The Institute, built in 1896, is of four stories, to which access is obtained by an electric lift and by two wide staircases. It comprises a main building and four detached houses, in addition to a farm, laundry, and electric station. It is within a short distance of the railway station. The various halls and rooms are well ventilated and lighted by electricity, and they all overlook the sea or the surrounding evergreen pine forests. The sanitary arrangements are on the latest and the most approved principles, insuring pure air, inside as well as outside. The system of drainage is all that can be desired, and special machinery has been erected for flushing sewers with electroliised sea water (Hermite's system), a remarkably efficient disinfectant and antiseptic. Drinking water of absolute purity is obtained from a deep subterranean sheet of water underlying the sandy soil, and no expense has been spared to make the arrangements as perfect and as complete as possible.

The treatment of patients varies, of course, according to the nature of the affection from which they are suffering. There is an admirable hydropathic department conducted by an experienced specialist of the celebrated Swiss school, under the control of a carefully selected staff of medical officers, according to the most approved Continental methods. It comprises hot and seawater baths, seaweed baths, electric brine baths, and hot air baths, together with vapour, douche, rain, shower and medicated baths. The brine is produced in the neighbourhood, where sea salt is produced on a large scale by evaporation, the mother liquor (a saturated solution) being thus available for therapeutical purposes. The services of experienced masseurs are available, and there is a medical gymnasium fully equipped with all modern appliances. The home farm is within reach of the main building. It insures a constant supply of fresh milk, butter, eggs, vegetables, and fruit, and houses the horses and donkeys belonging to the establishment. The laundry is on a magnificent scale, and it comprises a large disinfecting apparatus.

The marine open-air treatment is necessarily dependent for its success to a large extent on the resources at the disposal of the visitor for amusement and distraction. In this respect the Institut Verneuil is singularly favoured. There is a beach of fine sand extending several miles on either hand, sloping gradually into the sea, thus affording safe bathing at all hours of the day. At low tide the firm sand affords ample opportunity for tennis, cycling, &c. There are plenty of boats, and the outlying rocky islands provide objects for enjoyable excursions, fishing, shooting, &c. The roads in the neighbourhood are good for cycling, and there are numerous places of interest within easy reach.

It was impossible not to be impressed with the advantages which the Institut Verneuil offers for the regeneration of the debile and the recuperation of the convalescent. Nature has lavished her richest gifts, and art has supplemented them by providing all the comforts and appliances which favour recovery from disease. Last, but not least, La Baule is readily accessible from London, the journey not taking more than fourteen hours. The terms are very moderate, taking the luxury of the installation into consideration, ranging as they do from £3 to £4 a week for adults, and £10 to £12 monthly for children, exclusive of fees for medical attendance, baths, &c., which can be contracted for at a small additional cost. The only restriction imposed is that patients shall not be suffering from affections likely to incommode or prove injurious to the others.

The managing director is Monsieur A. Pavie, 4, Rue du Général Foy, Paris, from whom all particulars can be obtained.

France.

[FROM OUR OWN CORRESPONDENT.]

PARIS, July 30th, 1899.

HYSTERECTOMY.

At the meeting of the Société de Chirurgie, M. Ricord spoke on abdominal hysterectomy for uterine cancer and said that he had performed that operation ten times with only one death. The gravity of the operation was, consequently, in his opinion, not so great as was believed. None of his patients could have been operated on through the vagina, as the disease had in each case destroyed the greater portion of that organ. The speaker acknowledged that abdominal hysterectomy was a tedious operation, especially where the ligaments were infiltrated, but it had the advantage over the vaginal method that it permitted ablation of the infected glands.

M. Segond said that he performed ninety-five times ablation of the uterus by the vaginal method with a total mortality of 14 per cent.; most of the unsuccessful cases were those in which the vagina and the broad ligaments were invaded by the disease. As to the ultimate result of the operations, out of forty cases of relapse of which he had knowledge himself, the disease returned in thirty cases within the first year, seven in the second, one in the third, and one at the end of the seventh year. Among the cases that might be considered cured, one has already survived ten years, another nine years, two four years, and two two years. He only practised six times abdominal hysterectomy for uterine cancer. Surgeons, considering this method is superior to vaginal hysterectomy in the treatment of uterine cancer, believed that it was less grave than the latter, according to them, it was the only rational operation, permitting the removal of all the ganglions, and they hoped that by-and-bye the prognosis would be much more favourable than that given by vaginal hysterectomy. As to the gravity of the intervention, it was certain that, thanks to the perfecting of the method of operating, abdominal hysterectomy was as benign as vaginal hysterectomy, but it was none the less true that in cases where the extension of the lesions necessitated ligature of the iliac artery the operation could not be considered less grave than the vaginal method. Those who advocated the abdominal method gave for one of their principal reasons the facility with which the infected tissues could be removed, but that pretention was impossible to realise, for if some few glands were removed could the operator affirm that he left no tissue susceptible to be attacked by the disease? However, he admitted that for a cancer of the body of the uterus or for those forms complicated with softening of the neck, so that it did not afford a hold for the instruments, the abdominal method was the best. When the lesions were not limited to the uterus he never interfered, preferring palliative treatment, which eased the patient and prolonged her existence, frequently for a considerable period.

BLENNORRHOAGIA IN A BOY THREE YEARS OLD.

Nothing is more frequent than vulvo-vaginitis of specific origin in little girls in certain classes of society, as a consequence of the promiscuity in which the parents and children live and in which the gonorrheal virus

is communicated by the sheets, towels, or other instruments. On the other hand, urethral blennorrhagia is very rare in boys of tender age. Dr. Rouher reports a curious example of the kind.

He was called to a boy, aged three years, who, according to the mother, had not urinated for the previous three days. The penis was swelled, and pus flowed from the urethra. Another child of six years, who suffered each time that he tried to micturate for the last month, was also presented to the doctor. Here also by pressing on the penis a few drops of muco-pus were brought to the surface. On seeking the origin of the infection, M. Rouher learned that the two children slept in the bed with their eldest sister, who had herself suffered from acute gonorrhœa.

A CASE of infanticide was recently tried here, where the medical man who was called in showed up in rather a sorry light. The girl, a servant, being ill, he was asked to examine her. He came to the conclusion that she was five months' pregnant, and advised her removal to hospital. At the Hôpital Cochin it was found that she had recently been confined, and on search being made the dead body of an infant at term was found in a box in the bedroom. The doctor, in giving evidence, was fain to admit that he had only made a cursory examination, an admission which drew upon him some very pungent remarks from the bench.

A FEW days since a M. Vidal was sentenced to a fine of 1,000 francs and one month's imprisonment for the illegal practice of medicine. The curious feature in the case was that the accused, a commercial traveller, had succeeded in getting admitted to one of the services at Lariboisière hospital as a dresser, which post he had filled for three years.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, July 29th, 1899.

DIABETIC BLOOD.

AMONG recent discoveries one was announced for the detection of diabetes, by examining the blood with methylene blue, when a distinct red colour was evolved if sugar were present. If such a novelty could have been sustained it would have been of some practical value, but unhappily for the genius who startled the clinical world with such a simple means of diagnosis, the sugar is not the agent that strikes the red colour, but the acid of the blood which may occur in many other diseases besides diabetes. Schneider finds that a drop of urine added to normal blood will give the red colour that Bremer holds to be diagnostic of sugar.

The sugar in Bremer's new discovery is a mere accident, as any increased acidity of the blood will give the same reaction. This is Schneider's version of its diagnostic worth in medicine.

Müller, on the other hand, gives us a large number of experiments to confirm the accuracy of Bremer's deductions. Müller's earlier experiments were carried out in the morbid condition as well as the healthy, and found satisfactory. He goes further, and adds sugar to the healthy blood and thus obtains as positive a result as in the morbid condition. With this conflicting evidence before us we must pause before accepting the test as diagnostic or reliable.

SPINDLE-SHAPED DILATATION OF THE (ESOPHAGUS.

Schwörer relates a remarkable case of dilatation of the esophagus, caused by spasm of the cardiac end of the tube. The diagnosis was made during life, but was not confirmed till the post-mortem was performed. It was in consequence of a spasmodic attack when a bougie was used more violently or forcibly than usual that a rupture into the peritoneum took place, resulting in death.

ASEPTIC OPERATION WOUNDS.

Döderlein discovered some time ago that the fluids of the peritoneum after an operation were not free from germs which were attributed to the hands of the surgeon after a protracted operation in the abdominal cavity. These germs were shown to come from the deeper layers of the surgeon's hand which lay embedded below the epidermis, but became exposed after the epidermis was shed. This discovery led to the use of surgical gloves by some operators which Döderlein affirms is equally inefficacious, as no wound can be kept absolutely germ free.

He is not so reckless, however, as some who having discovered the impossible give a licence to operate in any manner. He charges the surgeon with grave responsibilities, and admonishes him to be more careful than ever by covering the hands with some impermeable medicated substance in order that the risk may be reduced to a minimum.

RUPTURED OVARIAN CYST.

Käppen records an ovarian cyst which he had diagnosed, but before operation was decided upon it suddenly burst. On operating, the peritoneum was found filled with a colloid material in which were seen large semi-solid masses of the same material. The whole was washed out and the wound closed and perfect recovery followed although the patient was collapsed at the time of the operation.

He relates another of a similar nature where chronic bronchitis existed, in which he used ether as an anæsthetic with an equally happy result.

THE SOURCE OF PAIN IN COLIC FROM BILIARY CALCULI.

It has frequently been asked, is it the calculus in the gall-bladder that causes the intolerable pain, or is the inflammation induced by the pressure of the foreign body? Different answers have been given by able physiologists. Bertelsmann places biliary colic on the same platform with colic of the bowel, and disagrees with Riedel that in all biliary colic there must be perialienitis present. Bertelsmann contends that the local inflammation which causes the bladder to contract is the cause of the pain, or at any rate the factor which makes it intolerable. If this be so the indications are antiphlogistic, but there are many cases with no inflammation whatever in which there is intolerable pain!

The Operating Theatres.

GT. NORTHERN CENTRAL HOSPITAL.

OPERATION FOR CARIES AND NECROSIS OF THE LOWER END OF THE FEMUR IMPLICATING THE POPLITEAL ARTERY AND VEIN.—MR. PEYTON BEALE operated on a boy, æt. 12, for caries and necrosis of the lower end of the left femur. The history of the case was of interest; the boy was originally admitted suffering from pyæmic abscesses over and around the right and left knee-joints, the right hip-joint, and in the left arm near the elbow-

joint. As so often happens, these abscesses did not then open into any of the joints. They were freely opened and stuffed, and those about the right hip and knee and left arm did well, one or two subsequent operations being needed to remove pieces of dead bone. In the case of the left knee however, the conditions became more serious. In spite of free incisions the joint became infected and had to be freely laid open and drained for some weeks. It eventually healed up leaving only two sinuses which led down to dead bone just above the intercondyloid notch of the femur. The present operation was performed in the hope that this dead bone might be removed completely. Before commencing the operation Mr. Beale stated that he had learned, by previous experience, to regard cases of this kind as very serious, for it commonly happened that the popliteal artery and vein were surrounded by pus, their walls were thus rendered very rotten, and both were liable to rupture at any moment. This fact rendered cases of the kind occurring in private practice much more serious than those in a well-equipped hospital where prompt and efficient aid was always speedily forthcoming. It was well, therefore, in operating on these cases to be fully prepared to ligature the popliteal artery or vein, or both, at a moment's notice. Mr. Beale then proceeded to enlarge the existing sinuses, first by the knife and then by Hilton's method, until the upper half of the popliteal space was laid fairly open, the popliteal vein and artery being both exposed to view. It was found, as expected, that the caries was very extensive, reaching into both femoral condyles; moreover, several flakes of dead bone which had peeled off the shaft of the femur were seen and carefully removed. During the removal of one of these pieces the popliteal vein suddenly burst. It appeared as if part of its walls, which were quite rotten, had suddenly given way. Both ends were at once clamped and securely ligatured. The dead bone having been removed, and the carious bone scraped out as thoroughly as possible, the wound was freely irrigated and stuffed with iodoform gauze. The popliteal artery was seen to be in a very unhealthy condition, but it was not ligatured then in the hope that its lumen would become more and more obliterated, and so collateral circulation would be established—if it had not already been fully established. The wound was dressed and the patient ordered to be removed to bed and watched carefully.

Mr. Beale stated that it was one of the golden rules of surgery to amputate at once should the main artery of the limb be wounded. He said that he had had under his care previously two cases exactly similar to the one on which he had just operated, but in those cases about three inches of the popliteal artery and vein were excised at the same time. In neither case had any gangrene supervened, and in one of them the carious and necrosed bone had been completely removed and the wound had healed up soundly. The other was still under observation, having still one small sinus in the ham. The point, he said, in these cases was that the collateral circulation became established during the time that the artery was exposed to the discharge from the carious bone and when the artery did give way, the hæmorrhage was very gradual at first and enabled the surgeon to tie the vessel above and below the rupture. Should secondary hæmorrhage occur, it was most essential to find the end of the vessel and apply a ligature about one

inch above it. That having been done, one could then consider whether it would be wise to ligature the femoral at once or not under these circumstances. Mr. Beale said he should ligature in Scarpa's triangle, taking the greatest care not to infect the wound from that in the popliteal space, but he would not amputate the limb unless other complications supervened. In these days amputation in such cases should be looked upon only as the very last resort.

It is interesting to follow the subsequent progress of the case. The wound was dressed on the second day and restuffed. On the fourth day the dressing was seen to be blood stained, and the house surgeon dressed the wound. He then saw that there was a small hole in the popliteal artery, from which blood was oozing, not spurting. The hæmorrhage was controlled by pressure and Mr. Beale was sent for. On his arrival he at once ligatured the artery above and below and excised about one inch of it, giving orders that if, in three or four days time, more hæmorrhage took place, a fresh ligature was to be applied upon the bleeding end. This expected hæmorrhage did occur and the house surgeon proceeded to look for the bleeding point; this, however, he was unable to find, so he ligatured the femoral at the apex of Scarpa's triangle. This operation controlled the hæmorrhage and the leg did not suffer in any way, thereby proving that the collateral circulation around the knee-joint had been fully established.

ST. THOMAS'S HOSPITAL.

HYDRONEPHROSIS FROM CONGENITAL DEFICIENCY OF URETER.—Mr. BATTLE operated on a girl, æt. 25, who was suffering from a tumour on the left side of the abdomen. The tumour had been noticed of varying size from time to time, and caused her a good deal of pain chiefly when large. She had not, however, noticed that there had been any increase in the amount of urine passed when the tumour had diminished in size. The swelling occupied the left side of the abdomen in the kidney region; it was dull on percussion, but the resonance of the colon could not be made out over it, fluctuation could be obtained; it was not tender. There was no rise of temperature; the urine was normal and her general condition healthy. The tumour was removed by the usual lumbar incision, being shelled out from the bed in which it was lying, a much elongated kidney being first met with; afterwards a cystic swelling, which had been partly emptied by a trocar and cannula introduced through part of the tumour, which was found to be chiefly kidney substance. The cyst-like part was found to consist almost entirely of the dilated renal pelvis and contained clear urine. The ureter left the cyst about three inches from its lower margin. It was much diminished in size, being represented by a small tube which only admitted a bullet probe: there was nothing obstructing it. No difficulty was experienced in ligaturing the vessels and ureter separately, but it was found difficult to reach them in the first instance on account of the large development of the cyst towards the aorta. The wound was closed in the usual way with deep and superficial stitches, and a drainage tube inserted. Mr. Battle said the absence of anything like renal colic made it likely that the condition was due to defect in the ureter, possibly as a result of kinking, but the condition found at

the operation made it probable the defect was of congenital origin.

It is satisfactory to state that the patient made an uninterrupted recovery.

“SALUS POPULI SUPREMA LEX.”

WEDNESDAY, AUGUST 2, 1899.

THE HOSPITAL QUESTION.

THE hospital question has been exciting a good deal of interest in London for some time. Our hospitals, great and small, were in low water. Their incomes had fallen off or their expenses had increased, and they were beginning to find themselves in difficulties. How to get money was the question, Charity with some does not always go hand in hand with Faith and Hope; and perhaps for this reason some take the view that “the greatest of these is Charity.” Important changes have taken place during the past half century, so far as the sick poor are concerned, in the relations between dispensers and recipients of Charity. The Fever Hospitals, Metropolitan Asylums, and Infirmarys, are not regarded as charitable institutions, any more than our Army and Navy. They are all supported by the State for its own benefit, and no sentiment of charity regulates the charges made on the people for their cost. Whether hospitals are needed now so much as they were, when little or no provision was made for the sick poor, we need not discuss. It certainly looks as if the sentiment of real charity in regard to hospitals was not active now, when we see appeals made through bazaars, balls, concerts, and fancy fairs for funds to help them. Is this a symptom of coming dissolution, preceded by expiring energy? It looks as if hospitals will have to be classed with

such social combinations as clubs, insurance companies, building societies, and many of the same character. Hospitals may be organised so as to provide not for the wants of poverty, but for those of sickness, that is for some of the accidents of life. If this is so, well and good. We shall then appeal to a sentiment altogether different from that of Christian charity. Our hospitals depended at one time largely on the influence of our clergy, through whom the most potent appeals could be made to the public. Through the great body of practitioners a great deal was done for our hospitals, more really than by any class, when legacies were being considered, or gratitude was having influence on those who wished to show sympathy for suffering, and could do so in no way better than through a hospital. We are rather doubtful now of the feelings of the clergy, and are not certain of those of the great body of practitioners towards hospitals. The institution of the Hospital Sunday has rather taken away the interest which certain of our clergy had always felt in certain hospitals, for in most parishes there existed a close relation between the sick poor and the ministers of religion. As regards the great body of practitioners, there is not the least doubt but that hospitals have injured them much in many ways, as those well able to pay their doctors have found they could do without them. Now the hospital authorities have resorted to another power to help them, and have appealed to Royalty for its patronage. The Prince of Wales has naturally done his best to assist, and for a time the result may be satisfactory. But only for a time, and sooner or later the collapse will come, if hospitals are to find support from charity. If we are asked what are the chief purposes for which hospitals are intended and on which their right of appeal to the public as charities should be based, we think that one of the chief is the advance and improvement of the Science and Art of Medicine, by which the whole people is benefited. One of the most important duties of hospitals is to educate those who are going to devote themselves to the practice of the profession. If the public does not require such servants, then hospitals as schools are not wanted, and the question of education does not come under consideration. It ought to be clearly recognised that the services of physicians and surgeons to hospitals must in some way be repaid. In old days, that is, about a century ago, when the Windmill Street School existed and the Hunters were the great teachers in London, education was a private matter. Things are changed since then, and now a special hospital may be worth a great deal more from a pecuniary point of view than even the chief of the general hospitals. Hospitals, particularly the specials, are advertising mediums, through which practice can best be obtained. There are some who take pleasure in teaching and who prefer it greatly to private practice, but if they can not afford to teach for little or nothing they must retire from hospital life. Whether the institutions supported by the State should be used as

schools of medicine, as they ought to be, particularly as the great class of infectious diseases are now removed from hospitals to which schools are attached, is a question which ought to be considered. Seeing there is not much hope of any great assistance being given to hospitals by the recent efforts made to obtain funds, we may leave the matter for the present *sub judice*, very much as the Transvaal affairs are being treated in the world of politics.

COMBINATION.

LANCASHIRE is well known as an active centre of "strikes"—as they are called—that is to say, of organisations trained to stand shoulder to shoulder and obtain a fair share of the wealth they are engaged in creating. That northern county, however, is now the scene of a combination of a novel character, the issue of which is fraught with importance to the future welfare of the medical profession. Strange as it may seem, the sturdy population of that busy district are slow to recognise in others the right to secure a fair remuneration for their services. There, as elsewhere all over the United Kingdom, medical men have been induced to act as the officers of lay societies upon terms that have become by degrees hopelessly attenuated and paltry; that have been conducted on lines of personal advertising and canvassing repugnant to professional traditions; and that have brought substantial profits to the coffers of these Societies. In other words, the trade societies have been astute enough to make money out of the members of a disorganised and disunited profession. The moral of the whole matter is clear as daylight. The weak strategical point is the want of organisation, and the remedy is common concerted action and proper generalship. That was the burden of the cry of the medical reformer fifty years ago, and that is the refrain he is still chaunting in the wilderness. But there are signs of hope that have for years past been steadily climbing up from the horizon. During the past fifteen or twenty years many associations of medical men have sprung into existence, with objects many and varied, but always with the central nucleus of some common interest to defend or foster. It is to such combinations that we must look for that self-help which alone can lead to salvation. Turning to the facts of the present deadlock, we find from the details, so far as reported, that the Lancashire Colliery Surgeons' Association, which is stated to have a membership of over one hundred, has become dissatisfied with the terms offered by a local friendly society. The origin of the dispute lay with the Wigan and District Miners' Permanent Relief Society, which has 20,000 members, and which refused to pay its medical officers what they considered adequate amounts for attendance in accident and other cases. The Wigan Society, not being able to come to terms, has engaged outside surgeons, who unfortunately are always forthcoming on such occasions. At that point in most instances the matter would have ended. The newcomers, having gained

a footing in the district by means that can hardly be described as creditable, would have gradually acquired practice at the expense of the gentlemen into whose shoes they have stepped, and by degrees the whole affair would have died out of memory, while friendly societies would have been the stronger by another victory scored over the medical profession. Fortunately, however, the colliery surgeons of Lancashire have had the prudence to unite and form a strong association, so that the cause of Wigan is not only that of a single district but also that of a large and important county. To replace the surgeons of a single society is one thing, but to find surgeons for a hundred societies is another and totally different matter. It is the old story of the colliers themselves, divided we fall, united we stand. The result of the present dispute should arouse the attention of the whole medical profession of Great Britain. Why should not a fund be raised to support the Lancashire surgeons in their spirited and resolute action? If they are to be left to fight their own battle without moral and material support from their professional brethren, then the outlook will be indeed hopeless. The association of the Lancashire surgeons is worthy of imitation in every county in England, and were there some universal system of such confederated bodies, the urgent need for reform in the medical profession would be to a great extent met. But how about the black sheep who have accepted the vacant posts at Wigan. It would be of interest to learn their names and antecedents. Would our friends the Medical Defence Union—"our hope for times to come"—undertake the task?

TUBERCULOSIS AND ITS PREVENTION BY DISINFECTION.

ONE of the results of the crusade against tuberculosis, now in progress, will be to impress the public with the fact that the disease is markedly contagious, and thus it is not difficult to foresee that as time progresses the conviction to this effect will become firmly established in the public mind. This then, having once taken place, one cannot avoid reflecting upon the possible results which are likely to accrue to the unfortunate persons who have been pronounced to be tuberculous. In all probability they will come to be regarded as tainted beings, sources of leprosy, so to speak, contamination, to be avoided at all hazards, and unfitted to mingle with the healthy portion of the community. If this state of affairs should come to pass it cannot be denied that those responsible for the present crusade against the disease will be answerable for it. At the same time who can doubt that the more tuberculosis is regarded as an infective malady the better are the results of its prevention likely to be. Carried, therefore, to its extreme, the warfare against tuberculosis will possibly, in the near future, enter upon a stage of expediency as opposed to sentiment. Under such circumstances the afflicted will have to suffer for the healthy; so much so, that, perhaps, complete isolation will come to be the rule among

those infected with tubercle. It is difficult, of course, to contemplate such an eventuation of a modern system of prevention of disease as this without feeling some pity for the hapless persons concerned. Nevertheless, further contemplation will show that the effects of this system will be likely to prove assertive far and beyond the persons immediately involved. Even the healthy members of tuberculous families will, perhaps, in the future be held to be ineligible for matrimony among families which are not tuberculous, and so it might come to pass that tuberculous families would have to limit their matrimonial undertakings to families of the same taint as themselves. This, of course, would be a most undesirable development of the tuberculous crusade, if it were to occur, and it would be calculated to defeat in a large measure the main object for which the movement has been undertaken. However, it is not only in this country that the trend of opinion, both professional and lay, is in the direction of making much of the infectivity of tuberculosis. For example, a paper was recently read before the American Climatological Association, in which it was pointed out that the larger and better class hotels at the different health resorts in the States are refusing to receive tuberculous patients. The result of this has been that the latter are now compelled to seek refuge in private houses, the proprietors of which are, so far, heedless as to the necessity of disinfection in such cases. For this heedlessness it is proposed to enforce disinfection under municipal authority, and thus, in view of such compulsion, the end may be that, rather than expose themselves to the trouble of this interference, the owners of private houses will deem it best to refuse a harbour of refuge to the hapless tuberculous person. We believe that in New York and Philadelphia the municipal disinfection system is already in vogue, and, therefore, it is quite likely that the plan will be adopted by other large cities. Taking then, all these facts into consideration, trouble appears to be in store for those who unfortunately happen to be infected with tuberculosis; let the public once firmly grasp that they are being taught to regard such persons as sources of dangerous contamination, and then sanatoria for their reception will become a matter of necessity throughout the country, and not, as now, merely a new method of profitable investment for capital.

Notes on Current Topics.

Plague in Europe.

UPON the appearance of the plague in Egypt we ventured to assert that its spread to European ports was simply a matter of time. From exclusive information which has come to hand it would seem not altogether improbable that the disease has broken out at Oporto. The facts of the case are that during the past few weeks there have been a number of suspicious deaths in the place mentioned, a promi-

nent feature of the sickness being swellings of the groin and axilla. Should this epidemic prove to be really plague the outlook is gloomy, for the wretched sanitary state of Oporto is notorious. Preventive medicine in that country is in a most elementary condition, and the ignorance and superstition of the population render special precautionary measures well nigh hopeless. If the disease which has invaded the important sea-port in question be not plague it is possible, in these days of practical bacteriology, for the authorities to settle the question within a few hours. We would suggest that not less in their own interests than in those of the rest of Europe the Portuguese Government should cause this most necessary investigation to be made forthwith. Under the stress of a threatened invasion by pestilences of the plague or cholera type the value of a prudent sanitary organisation is conspicuous and becomes an enduring comfort to the community that has set the house in order.

Boxing of Ears and Ear Disease.

THE fact that the boxing of ears is apt to set up serious middle ear disease has long been accepted as a canon in medicine. Indeed, no schoolmaster who is in touch with the times would resort at this time of day to the barbarous discipline in question. That a simple box on the ears may be a remote cause of death is readily capable of proof. The blow either ruptures the drum of the ear or sets up inflammation of some part of the auditory passages, septic processes intervene, and middle ear suppuration is established. The next step is the formation of a clot in the veins within the skull, in which they are anatomically in close connection with the internal auditory structures. As already hinted, this knowledge has long been a commonplace possession both of lay and of medical folk in our own country. It has only lately, however, received a practical recognition in Austria, where the absurd and childish practice of boxing the ears of soldiers has hitherto been in vogue. Instructions have recently been issued by the general in command of one of the army corps prohibiting both commissioned and non-commissioned officers in future from resorting to that degrading form of punishment. The reason given for issuing the order was the alarming increase of ear diseases in the Army. Of a truth, apart from sentiment, and viewing things in the cold dry light of experience, it were better to lash a soldier to the triangle and give him forty strokes with a cat-o'-nine tails than to box his ears. The one hurts and leaves a scar, the other permanently cripples, and perchance, kills.

Dangerous Advice.

THE prevailing cause of chronic inebriety is unquestionably the absurd habit of offering and accepting drinks, not because either party is thirsty, but in deference to a mistaken notion of good fellowship. By-and-bye the habit of taking drinks at odd times is formed, and so the drinking habit is gradually established. For this reason one cannot but deplore

advice, given ostensibly in the interests of temperance, when it takes the form of urging the drinker "to stop as soon as he has had enough." Yet this is apparently all the moral suasion which the Bishop of Ely cares to exert over his flock, judging from the report of a recent speech of his, which went the round of the Press. As well might one advise the reckless cyclist to stop on the down grade when he is going too fast. That is precisely what he often cannot do if he tries, and in respect of alcohol, moreover, the desire to stop is usually absent. Alcohol is an insidious poison, and the appetite grows by what it feeds on. It is comparatively easy to stop at the threshold, but every glass of liquor lessens the individual's power of self-control, and after a certain stage his one desire is to go a step further. The principle which ministers of religion and advocates of temperance should seek to inculcate is the desirability of struggling against the invading habit of indiscriminate drinking which is the root of the evil. It matters little what one takes with meals, the harm follows on the between-meal nips, and unless this fundamental weakness be resisted it is idle to talk of stopping at a particular stage on the road to ruin.

The London Hospital Sunday Fund Award.

THE large total (£50,716) reached by the Hospital Sunday Fund this year is inclusive of a donation of £10,000 from Mr. George Herring. But the Fund has other sources of income than that derived from the churches. It receives the interest from £45,000 Consols left by the Guesdon Trust, and the reversion belongs to it of £50,000 on the death of a lady. Altogether, with the addition of the collection this year, the Fund has now been the means of awarding a sum of £1,000,000 to the London hospital charities. Coming now to the awards, the first noticeable feature is that the unfortunate Queen's Jubilee Hospital is credited with "nil"—not the first time, by the way, in which this institution has been so dealt with. It would seem from this that the Sunday Fund authorities have not condoned the attack made upon the hospital by *Truth*. Either this is the case or the authorities of the hospital have failed to satisfy the requirements of the Fund as to the details of their management of the charity. In any case, to be publicly branded as unworthy of participation in the awards cannot fail to be damaging to the interests of the latter, and we should imagine that the Queen's Jubilee Hospital rather loses than gains by the efforts of its committee to obtain some recognition of its work from the authorities of the Sunday Fund. The next matter of interest is the award to St. Thomas's Hospital. This only amounts to £104 3s. 4d. Surprise must naturally be felt at the paltriness of this sum. But at the meeting of the Fund last week it was explained that the hospital was so largely endowed that its needs were small. We wonder if this expression of opinion has found favour with and been endorsed by the authorities of the charity concerned. For the rest it would be

interesting to learn the reasons for awarding £729 3s. 4d. to the Poplar Hospital, when the West London and Great Northern Central Hospitals are credited with £625 only. No one doubts for a moment the excellent work performed by the Poplar Hospital, but how can the large award to it be explained in comparison with that credited to the West London Hospital, an institution which is now recognised as being one of the most important centres of post-graduate tuition in London, and contains 152 beds.

The Punishment of "Peculiar People."

AMONG the cases tried at the Central Criminal Court last week was that of a man and his wife, members of the "Peculiar People," on a charge of manslaughter in respect to one of their children. The child, aged five years, fell ill, and in the course of a few days died, and the parents, in accordance with the custom of the sect, never called in medical aid. They were acquitted by the jury of manslaughter, but on the following day they were arraigned on a charge of cruelty and neglect. In the course of the case the defendants admitted that if one of their children were to sustain a fracture of the leg they would apply for treatment to a medical man. On the other hand, they advanced the curious argument that there was abundant reason for their refusal to seek medical aid, inasmuch as a neighbour had had three sick children attended by a doctor, and a fatal result had followed in each instance. It is, of course, impossible to argue with such persons, and doubtless recognising their inability to see the error of their ways, previous criminal court juries have avoided bringing in a verdict of guilty against "Peculiar People." However, since the law upon this point was settled by the Court for Crown Cases Reserved, matters have been different, and punishment is now being regularly meted out in these cases. In the present case the husband was sent to prison for six weeks, and the wife for one month. Parents are bound to provide medical aid for their children, and the law rightly takes no account of any conscientious scruples which they—as their guardians—may happen to hold against carrying out this necessary duty. As the judge remarked, it was impossible to believe that there was anything in Christianity which implied that children should be allowed to suffer from disease when they could be relieved by medical aid.

London and its Water Supply.

ALREADY, with the summer scarcely half gone, some concern is being expressed in regard to the possibility of a water famine in London this year. It has been pointed out that if the present dry weather continues a very serious state of affairs will ensue. Official returns show that during the month just ended the rainfall was quite inadequate to have any effect upon the sources of water supply, and it is even now admitted that unless rain in sufficient quantity to spoil the harvest and the enjoyment of

the holiday season were to fall, the situation would be scarcely changed for the better, owing to the intense dryness of the soil. It would seem that every year this question of the possible failure of London's water supply is becoming more and more one of urgency. The Thames cannot be relied on to meet the necessary requirements in this respect. The river remains the same in size while the metropolis grows, and the demand increases. Fortunately, other and purer sources are available in the "New River" and the "Kent" supplies, or London would, indeed, be in a sorry plight. It is even now a question whether the County Council will not eventually be compelled to consider seriously the proposed scheme of drawing a supply from Wales.

The Academic Costume Again.

A CORRESPONDENT in a contemporary has urged as a reason for endowing the Members of the Royal College of Surgeons, England, with an academic costume that they would be able to make use of it at the annual meeting of the British Medical Association, and he expresses, at the same time, the hope that in 1900 every member of the Association will be requested to wear a gown. But he goes further still. He thinks that a gown should be worn in the consulting room, and that medical men would command more respect and extract larger fees from patients if they were to prescribe thus academically clad. What a descent is this from high ideals to the low level of commercialism! We do not dispute that "fine feathers make fine birds," but we have yet to learn that patients are likely to be attracted by the costume, however gaudy, which their practitioner may choose to adopt. The public usually follow the custom of employing practitioners whom they find to be capable and trustworthy, and their respect and regard for their medical men are dependent upon those two qualities. It is, therefore, not in the least possible that they would be impressed by seeing their doctor in his consulting room robed in a gaudy hood; on the contrary, they would be much more likely to regard the matter from a humorous aspect, and associate the display with the development of an element of eccentricity in their medical adviser suggestive to them of the necessity of being watchful respecting his future proceedings. However, it is scarcely needful to condemn these suggestions. It is self-evident that they must be described as foolish. Let the Members of the Royal College of Surgeons ask the Council to procure for them a return of the number of Fellows of the College who have availed themselves of the privilege to procure a Fellow's gown, and then ask themselves whether agitation in favour of a Member's gown is worth the candle. We should not be surprised, if such a return were made, to find that not more than 2 per cent. of the Fellows had provided themselves with the gown designed for their special benefit, and quite possibly what would be true of the Fellows would be the case with the Members. As a

matter of fact, busy practitioners, whether Fellows or Members, have something more to think about than to trouble themselves concerning the question of an academic costume.

A "Haunted" Hospital.

WE gather from the *Liverpool Post*, that one of the large hospitals in the town—the name is not given—has the reputation of being "haunted." The apparition, which has frequently, so it is stated, appeared to the nurses of the institution, is that of a porter who, some years ago committed suicide by cutting his throat in in a small room off one of the landings, and was carried along the landing from the room to one of the large wards in which he died. "Now and again," continues our contemporary, "a nurse will see, either standing in some part of this corridor, as if awaiting orders, or walking along it a porter in the official uniform of the hospital. He appears in every respect an ordinary official, but on addressing him or in approaching him nearly he suddenly disappears. The matron evidently treats the matter as one of serious moment, for any mention of the 'ghost' is strictly forbidden among the nurses for fear of alarming the probationers." A haunted hospital is certainly a novelty in hospital life. But we should like to know, admitting the authenticity of the statements, what it is that has made the spirit of the porter uneasy? Possibly he has a grievance against a nurse who failed to treat his suicidal wound antiseptically. Or perhaps he has been making this special effort to reproach one of the medical staff who did everything that was possible to save his life. Anyhow, something should be done to "lay" the ghost, and no doubt this would be an easy matter as soon as the cause of the grievance was ascertained. We would suggest in the meanwhile, as a remedy, a fire hose containing a one in twenty solution of carbolic acid; as, however, the porter does not allow himself to be approached, it would be necessary to circumvent his wariness by special arrangements adapted for the purpose. Spraying a ghost with a one in twenty carbolic acid solution would be quite in keeping with the principle of sterilising instruments and other things regarded as indispensable in hospitals in the present day.

Food and Drug Adulteration.

SIR CHARLES CAMERON, M.P., deserves the thanks of everyone but the adulterators for his scathing denunciation of the Government Bill—as doctored up by the President of the English Local Government Board—for the protection of the trader. We have already spoken of this measure as being a wolf in sheepskin, an attempt, under pretence of protecting the public, to prop up trade interests. The real contest is between the vendors of margarine under the name of butter and the butter merchants, and between other traders in other commodities whose money interests are opposed, and the public is scarcely thought of in the dispute. The Government evidently think that the wholesale adulterators are a more useful voting force

than the tame and careless consumer, for its latest move has been to strike out of the Bill a clause which would have made the wholesaler legally liable if he issued an invoice of his adulterated stuff—falsely describing it under the designation of a pure article. The small shopkeeper, who is prosecuted for an adulteration of which, probably, he is perfectly innocent, is thus made a buffer upon which the sanitary authority may expend its energy intended for the real culprit—the wholesaler.

The Summer's Death Toll.

DELIGHTFUL as summer weather may be it, nevertheless, always exacts a death toll, especially among the infant population, and its death-dealing qualities bear an adverse ratio to the height of the temperature of the air. Thus the prevalence of the æstival wave of heat during the past few weeks has been associated with a gradual rise in the mortality throughout the country, mainly among the infant population. For example, last week, according to the Registrar-General's Returns, out of 4,028 deaths of all ages and from all causes, no fewer than 1,423, or 35 per cent, were infants under a year old. For the most part the increased death-rate is attributable to diarrhoea and dysentery, the origin of which is probably zymotic. Not even children who are nourished by their mothers' milk escape the diarrhœal attacks, although the mortality is much greater among those that are hand fed. It is certain, however, that if the present heat increases the infant death rate is bound to assume excessive proportions, inasmuch as the experience of previous years has taught that despite every care as to prevention and treatment fatal summer diarrhoea always accompanies a wave of heat.

The Effects of Vaccination in Germany.

THE anti-vaccinationists are a never-satisfied body—they always want to prove too much. They are claiming now that the Conservative party lost the Oldham election entirely as the result of the efforts of the anti-vaccinationists in the town. But it is scarcely needful to seriously discuss such a statement as this. We, therefore, deem it more to the purpose to direct the attention of the Anti-vaccination Society to the figures relating to the subject of vaccination in Germany. The statistics are remarkable. The population in Germany in 1871 was 40,000,000, and of these no fewer than 143,000 died from small-pox. After that year vaccination laws were introduced, making vaccination compulsory, and the result has been that the average number of persons who now die from small-pox in the Fatherland is 116. What more eloquent testimony than this could be wished for in order to show the value of vaccination? To dispose of such statistics as these is beyond the power even of the anti-vaccinationists, and their discontent under the circumstances is not surprising. But the general use of calf lymph is playing sad havoc with the anti-vaccinationist propaganda, and there are now reasons for supposing that the "tremendous experiment," such as the Vaccination Act

of last year was regarded, will in the end prove a very useful measure.

Arsenic in Thyroidism.

A FRENCH observer calls attention to a means of controlling the untoward symptoms which not unfrequently follow the administration of thyroid extract for obesity and goitre, and in certain diseases of the skin. He found that the exhibition of from two to twelve drops daily of Fowler's solution sufficed in most instances to obviate the palpitation, dyspnoea, &c., induced by a course of thyroid extract. The symptoms ceased when the arsenical treatment was instituted and reappeared when it was desisted from. As far as he could judge the co-administration of arsenic and thyroid extract, in no wise interfered with the therapeutical effects of the latter. We are familiar with the controlling effects of the arsenical treatment in affections, such as Graves' disease, which are supposed to be due to hyperactivity of the thyroid gland, and it is therefore, not surprising to learn that a similar controlling effect is produced on artificially induced thyroidism and the suggestion is one which deserves attention in view of the very large scale on which thyroid extract is now employed.

Vicarious Menstruation by the Ear.

DR. LERMOYEZ recently related before the Paris Hospitals Medical Society a curious case of vicarious menstruation. The subject was a girl who some years before began to lose blood periodically from the right ear. Every month, after some headache and general lassitude, an escape of clear non-coagulable blood took place from the auditory meatus, although on examination no local lesion or solution of surface continuity could be discovered. It was noted that the tympanum was intact. Three years after the onset of this irregular menstruation the function became established *per vias naturales*, and since that time the aural discharge had only recurred at rare intervals. Dr. Lermoyez regards the abnormality as a neuro-symptomatic manifestation of latent hysteria, inasmuch as examination revealed the existence of slight hypæsthesia of the tympanum and of the auditory canal, as well as a certain degree of auditory anæsthesia.

The Kissing Bug.

THE inhabitants of several cities in the United States are suffering from a sort of epidemic due to the bite of an insect to which the euphonic name of "kissing bug" has been given, by reason of its preference for the lips. There is nothing amusing about this animal apart from its name, for its kiss is followed very promptly by marked swelling, pain, and tenderness of the lips and adjacent parts of the face, sometimes culminating in unequivocal evidence of active cellulitis. The incriminated animal is described as about an inch in length, of a dark brownish-red colour, and is provided with six legs and long antennæ. Let us hope that our American Cousins will keep this offensive specimen of the

genus bug for home consumption as we have no use for it over here.

Ventilation and Change of Air.

SOME ingenious person has suggested that if people were careful to secure more perfect ventilation of their homes throughout the year they would be able to dispense with the costly obligation of taking a periodical holiday. There is certainly something to be said in favour of this idea since none would care to question the superiority of a constant supply of fresh air over casual indulgence therein. Our correspondent, however, overlooks the fact that holidays subserve other purposes than to secure an unlimited supply of pure air. They provide an opportunity for change of occupation, which is a form of rest, for relief from the intolerable monotony of the existence led by so many human beings in factories, offices, shops, and counting houses. Moreover, there is virtue in the mere change of air as this entails change of environment and habits. The hygienic value of a holiday largely depends upon the way in which it is spent, and this, of course, must vary according to the age, health, vigour, and tastes of the holiday-maker. The young and vigorous do not need physical rest, but change of habits; consequently a long journey by road, rail, or sea is preferred, while the middle-aged clerk, with no spare muscular energy, manifests a preference for a vegetative existence, free from the preoccupations and worries of his normal existence. The ever-increasing popularity of the cycle leads many people, physically unsuited for the strain, to undertake *tours de force* on wheels which, when reduced from theory to practice, prove the reverse of exhilarating. Fortunately, many of these persons are wise enough, at the end of the first day or two, to recognise the inanity of such excursions, and to abandon the trip, which has been the object of such elaborate preparations, in favour of a less exhausting method of whiling away the summer days. Every autumn, however, brings to one's notice a certain number of instances of heart strain unquestionably the result of ill-judged physical exertion during the holidays, and it behoves the middle-aged man more especially to bear this risk in mind when making his plans. Many of these cases, it is true, recover after more or less distress, but in a tangible proportion the cardiac function remains permanently impaired.

Presentation to Dr. R. Phillips Gelston.

A FEW days since the officers and attendants of the Clare Lunatic Asylum presented Dr. Gelston, late resident medical superintendent, on the eve of his departure from Ennis, with a beautiful illuminated address and a magnificent album-blotter, designed and executed in the most elaborate manner. The address was of the most eulogistic character, as were also the subsequent speeches of the representatives of the asylum officers and of the church. The affection entertained by the inmates of the asylum towards Dr. Gelston was testified by a presentation

to him at the same time from a female patient, consisting of two linen pocket-handkerchiefs, on which her imaginary initials (those of a really titled English lady) were beautifully worked with the needle, and which she inscribed "A slight token in kind remembrance."

Fees for Certifying Dangerous Lunatics.

AS we note that the new Guardians of the Boyle and other Unions have assumed the authority to "fix" the fee payable by them for the examination of dangerous lunatics at a much less sum than the £2 allowed by the Act of Parliament, we think it well to remind our readers that the Guardians' sole function is to pay what the magistrates order (under £2). They may advise or remonstrate, but they have no more legal authority in the matter than the blue-bottle which buzzes about the window pane. We would refer our readers to Clause 14 of the Dangerous Lunatics Act 38 and 39 Vict., Cap. 67, in proof of our contention.

Edinburgh University Graduation Ceremonial.

LAST Saturday the final wind-up of the University of Edinburgh's medical work for the year took place, a large number of degrees of M.B., Ch.B. being conferred, and a considerable number of men raised to the higher M.D. degree. Six of the theses for the latter received the coveted Gold Medal. One of the recipients of this honour being a lady practitioner. William J. Barclay, B.A., M.B., Ch.B., gained the "Ettler Scholarship," and a namesake of "Oom Paul," and, we believe, a nephew of his, the "Syme Surgical Fellowship."

A New Steriliser.

A NEW preparation composed of chlorate of potash and sulphuric acid has been introduced by Professor Bergé, of Brussels University. He claims for it that when brought into contact with water the chloric acid of the mixture becomes decomposed into oxygen and what he calls "Poleozone," which he says is the most energetic oxidising agent and bactericide known. Fishes and plants, he alleges, live well in water impregnated therewith, but that it at once destroys all microbic life.

PERSONAL.

MR. A. F. STANLEY, M.A., has been appointed Professor of Physiology in University College, Bristol.

MR. NORMAN HAY FORBES, F.R.C.S.Ed., has been appointed a Justice of the Peace for the borough of Tunbridge Wells.

MR. ROBERT O'CALLAGHAN, F.R.C.S.I., has been appointed surgeon and gynaecologist to the French Hospital, London.

DR. SUTHERLAND, Assistant Professor of Pathology in Glasgow University, was appointed on Saturday last to the Chair of Pathology in St. Andrew's University.

THE EMPRESS FREDERICK of Germany (Princess

Royal of England) has promised to lay the foundation stone next spring of the new building of the Nottingham Children's Hospital.

A BENEFICENT contributor, whose personality is only publicly known under the initial "M," has sent a further donation of £5,000 to the treasurer of Guy's Hospital for the re-endowment fund.

DR A. G. DAVEY, Senior Physician to the Royal Isle of Wight Infirmary, had the honour of being presented to the Queen on Saturday last on the occasion of the opening of the Children's Wing which has been built in commemoration of Her Majesty's long reign.

HER MAJESTY the Queen has bestowed the Decoration of the Royal Red Cross on Miss Leonora Maxwell-Muller, late Superintendent in the Indian Army Nursing Service, in recognition of her special devotion and competency in the discharge of her duties in the Army Hospital Corps.

THE BRITISH MEDICAL ASSOCIATION AT PORTSMOUTH.

MEMBERS of the Association may be congratulated on this year's choice of Portsmouth as a meeting-place. The interests associated with the town are many and varied, and there will be abundant opportunities for visitors to acquire new experiences, not only in intellectual but also in social and physical directions. As a seaport town and a centre of a busy shipbuilding industry the place has long been familiar, but it is best known, perhaps, in connection with the Government dockyards. It is practically continuous with the fashionable district of Southsea. Gosport is contiguous, and Southampton, the Isle of Wight, and the New Forest within easy reach. Visitors will have opportunities of visiting Netley and of inspecting some of the men-o-war stationed in the locality. Turning to the scientific aspects of the meeting, we find even more than the usual allowance of papers, of which it may be presumed a large number will be taken as read. Judging from past experience, there is some room for improvement in that direction, for not all the papers handed in to the honorary secretaries of sections have subsequently seen the light of day. So far as we have heard, however, the editor of the *British Medical Journal* is in no way responsible for this local process of editing by excision. At the same time it would be well if inquiries were made from the head office as to the ultimate fate of articles that have been handed to local secretaries. As a general rule, nothing but praise can be accorded to the organisation of the enormous amount of detail business that is involved in the conduct of so vast a concourse as that of the Annual Meeting. This year, for the first time, the railway companies have made a considerable concession to members of the association. Members who have signified their intention of being present at Portsmouth have received an official permit, on presenting which they will be enabled to secure a return ticket at a fare and a quarter. It is announced that the concession has been made this year as an experiment, so that it is to be hoped members will avail themselves of the opportunity thus offered to such an extent as to encourage the railway companies to repeat, if not to extend, these facilities in future.

Many matters of special interest to general practitioners are to be brought forward at the general meeting, which it is to be hoped will be attended by more than the usual somewhat scanty average of members. Such important questions as the licensing of midwives and of opticians by registered practitioners are down for discussion. Another point of special interest is the inquiry by the Coventry medical men why the recommendation of the Council of the Association made last year with regard to local friendly societies has not been enforced.

The entertainments are very numerous and varied, and include garden parties by Inspector-General Macdonald, C.B., and medical officers of R.N., and by Colonel Commandant Poore and officers of Royal Marine Artillery. Mr. Benjamin Barrow, of Ryde, the senior Vice-President of the Association, will also give a reception.

The annual dinner of the Association will be held in the handsome Town Hall on Thursday, and on the same evening a reception will be given by the Ladies' Committee; the Mayoress and Mrs. Lloyd will receive the guests.

The final general meeting will be held on Friday in the Albert Hall. The same day garden parties will be given by Mr. Montague Foster at Shiblington, and by Director-General Nash and officers of the R.A.M.C. at Netley. The Mayor gives a garden party on Wednesday at Melton, and a ball on Friday. Saturday will be devoted to the excursions, and Surgeon-General Cuffe, C.B., and the officers of the R.A.M.C. entertaining have invited a party of 200 to make a trip on the steamer *Dandis Dinmont* to Cowes and round the Isle of Wight.

On the evening of the same day the last ceremony of the meeting will be a grand Military Tattoo by massed bands of the garrison, a torchlight procession, and grand display of fireworks.

The forty-first annual meeting of the New Sydenham Society is announced for to-day (Wednesday), August 2, at five o'clock p.m., in Committee Room No. 1, Town Hall, Portsmouth. Business: Annual report, balance-sheet for 1898, election of officers for 1899-1900. The attendance of all members of the society is requested.

Altogether the prospects of the present meeting are brilliant. With a large attendance, perfect summer weather, and the social and professional advantages afforded by the neighbourhood, the meeting should be a red-letter one in the history of the association.

Medico-Legal Intelligence.

TALLERMAN v. THE DOWSING CO.

TREATMENT BY RADIANT HEAT.

AN application for an injunction was heard on July 19th and 20th by Mr. Justice Stirling in the Chancery Division of the High Court of Justice. As the case involves various points of interest to the medical profession, a short outline of the main features is appended. Counsel for Tallerman asked the Court to decide on the facts that the defendant Dowsing Co. had fraudulently used for their own purposes the case-notes and the testimonials of the plaintiff, and had fraudulently made use of the plaintiff's reputation, and that an injunction be granted to restrain such appropriation. A number of affidavits were put in on both sides, and the hearing of the case, which involved the arguing of a number of legal principles and other technicalities, occupied two days. The plaintiff's case

was briefly, that in 1893 he patented an apparatus for the application of dry air, a system of treatment that had been very successful. He had never advertised his methods to the public, but introduced them to hospitals, and trusted to cases, speeches, articles, and so on, published by medical men in the medical journals. Mr. Tallerman's Secretary, Mr. Pritchard, left him, and became secretary to the defendant company in March, 1899.

Two medical men, Dr. Sibley and Dr. Hedley, were also concerned in the case. With regard to Dr. Hedley, the plaintiff's position was thus defined in his evidence. Dowsing was instructed and aided in the manufacture of his apparatus and its application by Dr. W. S. Hedley, who had in the year 1894 been instructed by Mr. Tallerman in his treatment by hot air, and he became the plaintiff company's agent and representative in Brighton on the terms that the plaintiff company divided with him the fees received from patients for advice and treatment on his system. While occupying that position the said W. S. Hedley in the year 1895 constructed an apparatus which the plaintiffs alleged infringed the aforesaid patent, and he was called upon to surrender the apparatus. This he did, and further agreed not to be connected with the working of a similar one in future.

As regards Dr. Sibley, in August, 1896, that gentleman published in the *Lancet* an article on the Tallerman treatment, giving his experience at the North-West London Hospital, with which he was connected. The *Lancet* article had been edited and published in a pamphlet by the Dowsing Company as if it applied to the Dowsing treatment. Dr. Sibley's article was read in that way by the editor of the *Daily Mail*, who stated in a paragraph in his newspaper that the Dowsing bath had been favourably commented upon by Dr. Sibley in an article in the *Lancet*, and by Dr. Hedley, physician in charge of electro-therapeutics at the London Hospital. The *Daily Mail* article appeared in one of the pamphlets issued by the Dowsing Company. On May 6th, 1899, the *Lancet* said in an editorial note:—"We have seen the pamphlet and we cannot recommend its dissemination upon their business methods. It contains a mutilated article, the original of which was written by Dr. W. Knowsley Sibley in support of the Tallerman treatment. The title of the article is suppressed in the pamphlet. Dr. Sibley's words now wear the appearance of a commendation in the *Lancet* of some other treatment. Such tactics will not win the approval of the medical profession or the public."

Dr. Sibley also made a speech at the Balneological and Climatological Society during a discussion about March 1st, 1899, on the treatment of disease by heat. The report of Dr. Sibley's speech was not inserted in the next number of the *Journal of Balneology and Climatology*, but nevertheless appeared in the Dowsing pamphlet, but has since been printed in the journal. The published report contained the speech edited, but omitted all reference to the Tallerman method, just as in the *Lancet* article.

The position taken by counsel with regard to defendant was mainly that of legal objection to the form of the action in attributing fraudulent intention. It was several times suggested that if the dispute had been approached in a friendly spirit an arrangement might have been made. It was also stated that they were willing to say Mr. Pritchard should not be employed after September next. No affidavits were produced either from the last-named or from Dr. Sibley and Dr. Hedley. The defendant Dowsing, however, made the following statements in his affidavit:—"18. The article by Dr. Sibley in the *Lancet* of August 29th, 1896, contained a number of well-stated propositions applicable to any of the existing systems for the application of dry heat for therapeutic purposes. Believing that the copyright of the article belonged to Dr. Sibley, I asked if he saw any objection to my extracting from it these propositions for insertion in my company's pamphlet of extracts from the medical press. He assented to my doing so. My only object in thus acting was to utilise Dr. Sibley's general views of the principles common to the treatments of the

kind. Dr. Sibley was at that time acquainted with my apparatus. It is true that the remarks of Dr. Sibley to the Balneological Society referred to in plaintiff's affidavit do not appear in the April number of that Society's journal, though I understand they are intended to appear in the current number. I obtained from Dr. Sibley an advance copy of the number for insertion in my company's pamphlet and believe them to be a true report of what he said at the adjourned meeting of the said society on March 23rd, 1899. I inserted them exactly as received, and Dr. Sibley corrected my proof-print before publication. If there was any omission of a reference to the plaintiff's or any particular system in the original report it was made by Dr. Sibley himself. The proceedings at the adjourned meeting were too late for insertion in the April issue of the journal, which had gone to press. I am not aware that I have furnished these extracts in such a form as to prejudice or damage the plaintiffs."

With regard to the editing of articles, it was explained that Dr. Sibley objected to names. Plaintiff's counsel interposed by pointing out a difference between the balneological speech as quoted in the journal and in the Dowsing pamphlet.

The learned judge remarked that the alteration was in Dr. Sibley's handwriting, a fact at which he expressed surprise, and later:—"I cannot imagine that a professional physician like Dr. Sibley would deliberately falsify, for that is what it comes to, his own speech in order to give one an advantage over the other." After a prolonged hearing the learned judge reserved judgment, and added:—"I should be very unwilling to come to a conclusion that enough was proved in this case to justify the action in the form in which it is brought, but I have no hesitation in saying that, whatever the legal result may be, I think the defendant has made a mistake, and that the statements of fact which have been put into this pamphlet, and the article have been so modified as to produce a wrong impression on the mind of the reader; and, having regard to the statements in the affidavit of Mr. Dowsing himself that he desires to make his money by his own merit, I can hardly suppose that he will not take steps, whatever the law may be, to at once correct that erroneous impression."

Judgment accordingly reserved.

Laboratory Notes.

MARTELL'S "THREE STAR BRANDY."

We have carefully examined a sample of this well-known spirit by the usual tests, and the results obtained by analysis fully warrant our recommending it for medical and dietetic purposes. The analysis gave the following figures:—

Alcohol (as proof spirit)	...	86.5 per cent.
Extractives	...	68 " "
Ash	...	Nil.
Acidity036 " "
Ethers (as alcohol)028 " "

As appears from the above, it contains a relatively high percentage of alcohol, being well over the minimum alcoholic strength required by the New Food and Drugs Amendment Act (75 per cent. of proof spirit). The amount of ethers present is such as is usually found in genuine old brandies distilled from wine, and its flavour and aroma compare very favourably with those of similar high-class brandies. It is free from any undue amount of acidity, as well as from the various products met with in ill-matured spirits.

We analysed this product some ten or more years ago, and finding that it still maintains its exceptionally high character, we are consequently in a position to speak highly of it as a genuine old brandy made from wine, well matured, and free from all compounds which might detract from its value as a medicinal agent.

Correspondence.

We do not hold ourselves responsible for the opinions of our correspondents.

A DESERVING CASE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Being in the position to know the facts and circumstances concerning the regretted and unexpected death of Dr. W. B. Lauria on July 8th, I write to you on behalf of his wife and family in the hope that this appeal may not only reach the friends of Dr. Lauria, but also the charitable members of the profession. Dr. Lauria, through the effects of a severe accident, had been for nearly two years prevented from practising his profession. Directly his health permitted, he secured an appointment at Lagos, but shortly after taking up his work there he succumbed to the deadly nature of the climate. Dr. Lauria leaves a widow and three children quite unprovided for. All subscriptions to the Dr. Lauria Fund should be sent to Dr. Beers, 6, Wandsworth Bridge Road, London, S.W., or to Dr. Hartnell, 1, Rye-croft Street, Fulham, S.W.

I am, Sir, yours truly,

VICTOR HORSLEY.

25, Cavendish Square, London, W.
July 27th, 1899.

Obituary.

PROFESSOR JOSEF MAYER, OF CRACOW.

WITH the death of Professor Mayer, whose name is so well and favourably known in this country, Cracow has lost one of its most prominent members. He was born in Cracow 1808, where he studied and took his degree in 1831. In 1833 he was appointed Professor of Medicine in the Jagiellon University of Cracow. In 1848 he was appointed Rector, and inaugurated many reforms. In 1877 he retired from professorial work and devoted himself wholly to literature and scientific investigation, on which he was a varied and prolific writer. He was the founder of the first medical paper in Poland—viz., *Przegląd Lekarski*, still the leading journal in that country. During his lifetime Franz Josef had conferred on him many honours and titles of dignity. He had entered on the ninety-second year of his age at the time of death.

Medical News.

Careless Death Certification.

AN inquest was held a few days since at Hammersmith on the body of a child who had been attended by an unqualified person of the name of Achille Monpalao, who claimed to possess an Italian diploma. The child had previously been seen by Mr. Swindale, a local practitioner, who ultimately certified the death when Monpalao declined to give one. We would advise Mr. Swindale to be more careful in future in certifying the deaths of persons attended by unqualified persons, especially as in this instance he was rebuked by the coroner for his laxity in the matter. Just to show how necessary is a reform of the laws in this respect we may add that on inquiry it turned out that the death had not been registered at all, and the child was buried without the production of a registrar's certificate. It is to be hoped this incident will receive attention at the hands of the proper authorities.

The Royal University of Ireland.

At the meeting of the Senate on Friday last, Sir Thomas Moffett in the chair. Mr. Dease, Dr. Allman, Dr. McKeown, Dr. Macalister, Most Rev. Dr. Healy, Bishop of Clonfert, Rev. Dr. Delany, Sir William Thomson, His Honour Judge Shaw, Sir Christopher Nixon, Dr. Sinclair, Right Rev. Monsignor Molloy, Rev. Dr. Hamilton, Dr. Leebody, Rev. Dr. Brown, Dr. Cox, and Right Hon.

Mr. Justice O'Brien. Sir James C. Meredith and Dr. M'Grath, secretaries. A letter was read from Miss Redington thanking the Senate for their resolution of sympathy passed at last meeting. Her Majesty's Royal Warrant was received appointing Lieutenant-Colonel John G. F. Ross, of Bladensburg, C.B., to the vacant seat on the Senate. The Right Hon. Lord Morris, LL.D., was unanimously elected vice-chancellor. The reports upon the results of the summer examinations were considered, and passes, honours, exhibitions, &c., were awarded in connection therewith. It was resolved that history be inserted in the list of subjects of examination at Second University. The following resolution was adopted:—"That the Senate accepts with great regret Dr. John Campbell's resignation of his fellowship, and desires at the same time to express its high appreciation of his devoted services to the University during the long period of seventeen years for which he has held that office."

Measles at Liverpool.

DURING the last six weeks no less than two thousand cases of measles have occurred at Liverpool, and the epidemic has been followed by a disquieting increase in the mortality returns. The Medical Officer of Health reported that a drop had taken place on the closure of the board schools. Forty-one elementary schools have had to be closed on account of the epidemic.

Respecting Leicester Guardians.

THE judges of the Queen's Bench Division have granted a *mandamus* to the Leicester guardians to appoint a vaccination officer in accordance with the Statute, but seven days' grace has been accorded in view of an appeal. On their return home a large and enthusiastic crowd, duly garnished with brass and other wind instruments, met them and serenaded them to the Floral Hall, where a meeting was held, at which much perfervid oratory was disposed of. This is a victory for the Local Government Board, and we shall await the next stage of the proceedings with interest.

The Clerical Botanist.

THE trial of the LL.D. and ex-clergyman, on a charge of manslaughter, came off on Saturday last at the Central Criminal Court. The prisoner, who practises as a medical herbalist, had attended a child suffering from diphtheria which he had not recognised, with the result that the child died and another child contracted the disease. The medical evidence tended to show that the treatment was altogether unsuitable, and even injurious, and after a patient trial the jury returned a verdict of guilty, coupled with a recommendation to mercy, based apparently on the implicit confidence which the prisoner evinced in his ignorant practices. In the upshot he was let off with two months' imprisonment.

PASS LISTS.

Society of Apothecaries of London.

During the examinations in July, 1899, the following candidates passed in:—

Surgery.—R. P. N. B. Bluett, H. R. Cross, A. B. Dunne (Sections I. and II.), A. D. Evans, F. R. Featherstone (Sections I. and II.), C. Fisher (Sections I. and II.), J. E. Griffith, E. S. Johnson, F. S. Leach (Section I.), G. S. Moore, O. H. Rogerson (Section I.), A. F. Weston (Section I.), C. C. Worts, T. H. B. Yorath.
Medicine.—F. G. Aldrich (Section I.), R. P. N. B. Bluett, T. S. Elliot (Section I.), H. Fawcett, E. L. Gowland (Sections I. and II.), H. M. Hardy, O. E. Lemin (Section I.), R. A. Lyster, V. S. Partridge (Section II.), J. W. Robertson, F. C. Torbitt, L. E. Whitaker (Section I.), W. H. Willcox, E. D. Wortley (Section I.), T. Young (Section I.).
Forensic Medicine.—R. P. N. B. Bluett, T. S. Elliot, E. L. Gowland, H. M. Hardy, O. E. Lemin, R. A. Lyster, W. P. B. Newth, E. S. Pushong, L. K. Tickner, F. C. Torbitt, W. H. Willcox.
Midwifery.—M. A. Alabone, R. P. N. B. Bluett, A. M. Davis, C. A. W. Egan, H. C. Holden, H. R. Miller, A. C. Oliver, E. S. Pushong, G. M. Smith, L. K. Tickner, S. J. Welch, L. E. Whitaker, W. H. Willcox.

The diploma of L.S.A. was granted to the following candidates, entitling them to practise medicine, surgery, and midwifery:—

R. P. N. B. Bluett, H. R. Cross, A. D. Evans, E. L. Gowland, J. E. Griffith, E. S. Johnson, G. S. Moore, V. S. Partridge, J. W. Robertson, L. K. Tickner, W. H. Willcox, and T. H. B. Yorath.

Notices to Correspondents, Short Letters, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

LOCAL REPORTS AND NEWS.—Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sending them to the Editor.

READING CASES.—Cloth bound cases, gilt lettered, containing twenty-six strings for holding the numbers of THE MEDICAL PRESS AND CIRCULAR, may now be had at either office of this journal, price 2s. 6d. These cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

REPRINTS.—Authors of papers requiring reprints in pamphlet form, after they have appeared in these columns can have them, at half the usual cost, on application to the printers before the type is broken up.

ORIGINAL ARTICLES OR LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

"LENNOX" IN THE "ECHO."

As an example of the freedom with which certain evening "rags" publish mendacious statements, a correspondent calls our attention to the utterances of the notorious "Lennox" in a recent issue of the *Echo*. He asserts that the large amounts subscribed to hospital funds by the public avail the public but little, because, forsooth, "the honorary staff draws the money and the patients are treated like cattle." How the "honorary" staff can draw the money this disreputable correspondent of a not less disreputable journal does not stoop to explain. He vouchsafes the information that he has been served with a writ in an action for slander, and if his utterances in regard to private individuals are characterised by the wanton mendacity of his remarks on professional men in general, the issue of the action ought to be tolerably certain.

INEX.—You will find all the information you require in our Educational Number, which will appear very shortly.

A WARNING TO SPRAYERS.

The latest adulteration vagary is the colouring of ordinary coppers with Prussian blue and selling it for wheat and potato spraying (for which it is totally ineffectual) as sulphate of copper. This fraud has been recently brought to notice by Dr. Vaelcker, Public Analyst for the Bath district, who believes that it has been, already, very prevalent.

"**SECRETARY**" asks:—"Where are advertisements for secretaries of hospitals, &c., most likely to be seen? They do not appear in the medical journals, and very rarely in ordinary dailies." The position is usually non-medical, and, therefore, when advertised at all the announcement is generally to be found in the daily press. But, very often, the appointments are made without advertisement.

TAITIAN.

A correspondent writes:—"Can you inform me where I can find Mr. Lawson Tait's 'General Summary of Conclusions from 4,000 Consecutive Cases of Abdominal Section' 1894? It is entered in the 'Medical Directory' under Mr. Tait's name, but with no reference to any journal. A former colleague of the deceased informs me that he has no idea where it appeared, but he fancies that it was published in parts in the MEDICAL PRESS AND CIRCULAR."

The majority of Mr. Lawson Tait's communications of late years have appeared in this journal, but we cannot trace the Summary alluded to in 1894. A brief summary of "The Life of Lawson Tait" has recently been issued (price 6d.), by Messrs. Baillière Tindall, and Cox, which contains a good many interesting notes. **ED.**

MR. WYNTER will receive a private note as soon as the necessary inquiries are complete.

SOAPSTONE FLOUR.

The Secretary of the State Board of Agriculture (Maine, U.S.), has issued, by circular, a warning to the public that flour is being now adulterated, to a considerable extent, with "mineraline," which is nothing more nor less than ground soapstone. We have often heard of bone dust as a constituent of bread, but this seems to be a distinct improvement in adulteration, at least in point of sentiment!

Vacancies.

Birkenhead Union.—Assistant Medical Officer for the Infirmary Workhouse and Schools. Salary £20 per annum, with board, washing, and apartments. Applications to the Clerk of the Guardians, 45, Hamilton Square, Birkenhead.

Cheltenham General Hospital.—Assistant House Surgeon for two years, unmarried. Salary £100 per annum, with board and lodging.

County Asylum, Gloucester.—Junior Assistant Medical Officer, unmarried. Salary commencing at £120 per annum, with board (no stimulants) and washing.

Down Infirmary.—Registrar, Assistant-Surgeon, and

Apothecary. Salary £63, with board, lodging, washing, &c. Applications to Dr. Tate. (See advt.).

Denbighshire Infirmary, Denbigh.—House Surgeon. Salary £20 per annum, with board, residence, and washing.

Dundee Royal Lunatic Asylum.—Medical Assistant. Salary £100 per annum, with rooms, board, and washing.

Ennis District Lunatic Asylum.—Resident Medical Superintendent. Salary £350 with extras valued at £110 per annum. Applications to the Chairman. (See advt.).

Enniskillen Union.—Medical Officer *pro temp.* Remuneration £3 3s. per week. Applications to the Guardians. (See advt.).

Halifax Royal Infirmary.—House Surgeon, unmarried. Salary £20 per annum, advancing £10 a year, with an extra allowance of £9 2s. 6d. per annum. Residence, board, and washing provided.

Hospital for Consumption and Diseases of the Chest, Brompton.—Assistant Resident Medical Officer. Salary £100 per annum, with board and residence.

London County Asylum, Cane Hill, Purley, E.S.O.—Junior Assistant Medical Officer. Salary £150 per annum, with board, furnished apartments, and washing. Applications to the Clerk to the Asylums Committee, 6, Waterloo Place, S.W.

Lunatic Hospital, Nottingham.—Assistant Medical Officer, unmarried. Salary £150 a year, with furnished apartments, board, attendance, and washing.

Oldham Infirmary.—Senior House Surgeon. Salary £25 per annum with board, washing, and residence. Also Locum Tenens. Three guineas.

Rochdale Infirmary and Dispensary.—House Surgeon, unmarried. Salary £20 per annum, with board and residence.

Royal Hants County Hospital, Winchester.—House Surgeon. Salary £65 per annum, rising to £75, with board and residence.

Roxburgh District Asylum, Melrose.—Assistant Medical Officer. Salary £100 per annum, with furnished quarters, board, washing, and attendance.

Seamen's Hospital Society (Dreadnought), Greenwich.—Senior House Surgeon for the Branch Hospital in the Royal Victoria and Albert Docks, E. Salary £75, per annum, with board and residence and an additional £25 per annum if certain clinical work is performed satisfactorily.

West Bromwich District Hospital.—Resident Assistant House Surgeon. Salary £50 per annum, with board, lodging, washing, and attendance.

Western General Dispensary, Marylebone Road, London, N.W.—Second House Surgeon, unmarried. Salary £20 a year, with board, and residence and 10s. a month for washing.

Appointments.

ARMSTRONG, HUBERT, M.B., Ch.B. Vict., Honorary Assistant Physician to Infirmary for Children, Liverpool.

BAKER, OSWALD, L.R.C.S., L.R.C.P. Edin., Physician to Out-Patients of the Seamen's Hospital Society, Greenwich.

BOYD, F. D., M.D., F.R.C.P. Edin., Assistant Physician to Edinburgh Royal Infirmary.

DUNCAN, ANDREW, M.D., F.R.C.S., Physician to In-patients of the Seamen's Hospital Society, Greenwich.

HALL, C. BEAUCHAMP, F.R.C.S. Eng., District Surgeon to the City of London Lying-in-Hospital, City Road.

LYLE, H. S., M.B.C.S., Senior Medical Officer to the Liverpool Cancer and Skin Diseases Hospital.

MCCREA, PHILIP WM., A.B., M.D., B.Ch., B.A.O. Dubl., Deputy Public Vaccinator for the Ashley District Union.

MCGAVIN, LAWRIE HUGH, M.B.C.S., L.R.C.P., Surgical Registrar and Tutor to Guy's Hospital, London.

MAHONY, M. J., M.B., B.Ch. Irel., Senior Medical Officer to the Liverpool Cancer and Skin Diseases Hospital.

PREDMORE, JOHN WALTER, M.B.C.S., L.R.C.P. Lond., Assistant Medical Officer to the St. Saviour's Infirmary, Dulwich, London.

RENTSCH, S. H., L.R.C.P. Lond., M.B.C.S., Divisional Surgeon to the Cornwall Constabulary.

RICE, DAVID, M.R.C.S. Eng., L.R.C.P. Lond., Assistant Medical Officer to the County Asylum, Cheddleton, Staffordshire.

SHENNAN, T., M.D., F.R.C.S. Edin., Pathologist to the Royal Hospital for Sick Children, Edinburgh, and to the Leith Hospital.

STILL, G. F., M.A., M.D., M.B.C.S., Assistant Physician for Diseases of Children at King's College Hospital, London.

WAT, MONTAGUE H., M.B.C.S., L.R.C.P. Lond., Assistant House Surgeon to the Royal Portsmouth Hospital.

Births.

GARMAN.—On July 24th, at Oakeswell Hall, Wednesbury, the wife of Walter Garman, Esq., M.D., of a daughter.

MONRO.—On July 27th, at 17, Queen's Gardens, Muswell Hill, N., the wife of J. D. R. Monro, M.B., of a daughter.

Marriages.

BAILLIE—GOULD.—July 27th, at Park Church, Grosvenor Road, Highbury, James Baxter, son of the late Alexander Baillie, Kinnaird, Forfarshire, to Annie, eldest daughter of William Gould, M.D., of Highbury.

BARENDT—CROWE.—July 27th, at St. Augustine's Church, Liverpool, by the Rev. W. J. Adams, Vicar, assisted by the Rev. J. Henderson, Rector of St. Pancras, Chichester, Frank Hugh Barendt, M.D. Lond., F.R.C.S. Eng., of 65, Rodney Street, Liverpool, third son of the late D. E. Barendt, of Liverpool, to Mary Burchall (May), eldest daughter of Mrs. Crowe, 47, Bedford Street, North Liverpool.

Deaths.

MOTT.—On July 27th, at St. Leonards-on-Sea, Marcus Wm. Mott, M.D., aged 69, son of the late Chas. Mott, of Church Stretton.

The Medical Press and Circular.

Original Communications.

RECENT ADVANCES IN PRACTICAL MEDICINE. (a)

By SIR RICHARD DOUGLAS POWELL,
Bt., M.D., F.R.C.S.,

Physician in Ordinary to Her Majesty the Queen.

THE author dwelled upon the comparatively short time that had elapsed since the introduction of many appliances now in general use, such as the stethoscope, the clinical thermometer, &c. He then reviewed the present position of bacteriology, and its bearings on susceptibility or immunity, passing on to discuss the prevention and treatment of tuberculosis. Among the questions that have in the present year ripened considerably, and have been urged forward strenuously towards a final settlement, that of the prevention and treatment of tuberculosis has, he observed, taken a very prominent place, and it is impossible not to allude to it here, although it will be the subject of a special discussion in the Medical Section. Truly a disease which still claims one-ninth of our mortality may well command our deepest interest. That much has been done to diminish our national liability to consumption by improved sanitation on general grounds by Parkes, Simon, Bowditch, Buchanan, Milroy, MacCormac, Smith, Greenhow, is evident by the gradual reduction of the mortality in the last half century from 38 to 14 per 10,000 living, or in proportion to the population for England or Wales by one half since 1851 (Tatham). Even in comparing the quinquennium 1875-79 with that of twenty years before, Longstaff found that the mortality from phthisis at the ages between 5 and 35 had decreased by 15 to 28 per cent., and he could say in 1884 that "the decline of the deaths in recent years is chiefly to be attributed to a diminished number of deaths assigned to fever and phthisis." All this had been effected without direct reference to the special bacillus element in the disease, chiefly by amending those conditions to which he had alluded as being intermediate between the bacillus attack, of which most of these pioneers in tubercle sanitation knew nothing, and the illness of the patient.

That it is *au fond* a right grouping to place all the previously ascertained causes of consumption among the predispositions, and to regard the disease itself as produced by definite infection or contagion through the inhalation of sputum dust, or by the ingestion of tuberculous foods, had been accepted at least for the last ten years; but, he urged, we must not discontinue to attach a due importance to the other etiological factors because one of them may seem *primâ facie* to be sufficient. To set heredity at naught, to regard climatic considerations as of no importance, and to state that the disease is always acquired by direct contagion or infection is, in his opinion, to ignore much that is true, and to magnify that which should be carefully guarded from exaggeration.

Thirty years ago Sir W. Jenner, in an address to the Epidemiological Society, declared the transmission of tuberculosis from parent to child to be one of the best-established facts in medicine. Jenner did not mean by this the actual transmission of tubercle, nor has anyone that I know of, in modern times at least, made any such contention; but that the susceptibility to become tuberculous runs in families, and this I must confess remains with me an unshaken belief. Take, for example, on the one hand, the striking account by Dr. Reginald Thompson of 80 families of consumptive parentage yielding 385 children, of whom 194 became phthisical and 37 died in infancy, leaving only 154 exempt. Consider this in account with the unproven direct communicability of the disease to which I shall presently allude, as shown by the distribution of mortality among married people compared with their numerical liability as members of the general public, and the case for heredity as a predisposing cause of consumption is a strong one if not still "one of the best-established facts in medicine." We cannot, of course, prevent consumptive people from marrying; there are exceptional conditions under which they may rightly do so, but the advice of the family physician should be steadfast in discouraging such alliances, which are unfortunately often prolific. Life assurance offices, whose calculations are based upon experience, will probably wait for much further evidence against the heredity of phthisis before they will feel justified in accepting without surcharge the lives of those who present a consumptive family history.

We are all familiar with circumstances connected with the incidence of certain cases of tuberculosis which render it probable that they have been acquired by indirect contagion through the contaminated dust of dirty rooms, and know that under certain conditions of stagnant, dark surroundings a patient with advanced phthisis of unclean habits would cause local danger of tuberculous infection to his attendants and friends, and to future occupants of the room. But except under such and similar almost experimental conditions the evidence of the contagiousness of phthisis is extremely slender.

It, for instance, has not been proved that tuberculosis is more prevalent among married than single people, and Dr. Longstaff has shown that normal co-incidence would account for more than the deaths reported. Pulmonary consumption is comparatively rare before puberty, infantile mortality being almost exclusively from bowel consumption through milk infection. Tuberculosis is nearly twice as frequent among male as among female infants. The mortality from tuberculosis has diminished more greatly, by from one-third to one-fourth, among females than males above the age of 20 in the last 30 years (Hugh Beevor), when one would think that industrial, nursing, and indoor conditions generally would have told against the female in this respect. The records of the officials and servants of one of our largest consumption hospitals taken out for 50 years, including a period precedent to the use of any special preventive measures beyond those of ordinary sanitation, show a death-rate not in excess of that of the ordinary population.

(a) Abstract of address delivered at the annual meeting of the British Medical Association, August 1899.

Whilst, therefore, on the one hand advising every ordinary measure of cleanliness, avoidance of dust, and proper disposal and disinfection of sputum, we may, and indeed must, avoid all exaggerated statements calculated to alarm the public as to the contagion of phthisis. In respect of sanitary precaution he instanced the simple and efficient directions of the Medical Officer of Health for Brighton as being in most reassuring and refreshing contrast to the theoretical and alarming precautions printed for some other health resorts and published on no official authority. These directions are privately sent through the medical practitioner to the person affected.

It is again difficult to recognise the striking testimony of such trustworthy observers as Middleton, Bowditch, and Buchanan as to the influence of a wet subsoil on the prevalence of consumption with the present view of the acquirement of the disease only by human and bovine infection. We must recall, too, to mind the enormous prevalence of bovine tuberculosis, not be it observed only among stall-fed, crowded, and insanitary cattle communities, but among animals under good open-air conditions. Do we not find in this prevalence of tubercle among pasture-fed cattle, and in the fact of the prevalence of the disease in localities with wet subsoils and deficient sunlight, some probability that the tuberculous organism, like those of actinomycosis, tetanus and anthrax may have an independent and parasitic existence, and that like malaria tuberculosis will probably be found to have a double origin from purely microphytic as well as from parasitic infection.

It is remarkable that two at least of the most deadly of disease microbes, tetanus and anthrax, should be normal inhabitants of the soil, and yet how comparatively scarce these diseases are, and, as regards one at least, how communicable. It would seem that, as is the case also probably with malaria, whilst the ultimate source of the disease is vegetation in the soil, yet a greater virulence and activity is attained, and for a short time maintained by cultivation in the human body, or in that of certain other warm-blooded animals. With regard to tuberculosis he pointed out that whilst we may hope on the one hand by further careful sanitation, by destroying and diminishing the careless distribution of bacillary dust, and by withdrawing from human consumption tuberculous foods, still to effect a considerable inroad upon the remaining 14 per 10,000 mortality from consumption; we cannot afford, on the other hand, to withdraw or relax precautions dictated by observations, sound in themselves, although in some regards capable of amended explanation, or we may have to make some deductions from the two-thirds diminution in mortality already achieved. There is probably a mephytic laboratory beyond our special control, yielding organisms ever ready to attack the unwary and those whose vitality is depressed. General sanitation and cleanliness is our first line of defence against them all. Wherever the conditions of insanitation, dampness, deficient sunlight, and the prevalence of favouring diseases are present there aggressive activity may be again looked for.

A SKETCH OF THE CENTURY'S PROGRESS IN

MEDICINE AND SURGERY. (a)

By J. WARD COUSINS, M.D., F.R.C.S.,

Senior Surgeon to the Royal Portsmouth Hospital.

AFTER reviewing the state of medical science at the beginning of the century, the orator referred to

(a) Abstract of Inaugural Address delivered at the meeting of the British Medical Association at Portsmouth on August 2nd.

the history of vaccination, and deprecated the ill-advised action of the Legislature in deliberately minimising the protection which Jenner's discovery was the means of affording.

Passing on to the subject of pathology, he observed that the early part of the century will ever be recognised as the birthtime of modern pathology—the period when the huge chasm between dead morbid anatomy and living pathology began to be bridged over. The teachings of John Hunter had long exploded the old humoral theories of disease. The leading minds in those days no longer considered that disease depended upon an excess of bile, or blood, or phlegm, and the other fluids of the body, and that it could be cured by getting rid of these faulty elements. The principles formulated by Hunter were maintained by succeeding writers in the same field for many years. His pathology was a long way in advance of his predecessors, and he was the first to recognise that all the processes of the organism belonged to biological science.

To-day, he observed, we are able to appreciate the fact that the evolution of our new pathology has progressed side by side with the evolution of biology, and that, in its broadest sense, pathology is an outgrowth of biology. The work of the last fifty years may be rightly defined as the great unravelling of the deep relations between the healthy phenomena of life and the variations which are outside the normal cycle of these vital phenomena. Through many years biology and pathology have been mutual helps in their onward and remarkable evolution, and we may rest assured that in the coming century their healthy reaction on each other will still go on. Pathology will still advance, and the new discoveries of biology will serve as starting points of new pathological truths; at the same time, the ordeal of biological criticism will be accepted as the test of every new pathological development.

The orator then discussed the relations between the disorders of mankind and those of the lower animals. Recent investigations in bacteriology, he said, have proved a great stimulus to the study of the relations between the diseases of mankind and those of the lower animals, and this relationship will form an important part of future researches. It is only a few years ago that the real nature of that dreadful scourge of the human race, tuberculosis, was discovered, and its intimate association with the same disorder in domestic animals clearly brought to light. Laennec was the first observer who described tuberculous nodules, and traced their development from miliary tubercles. In 1865 the inoculation of animals with caseous material was found to produce tiny masses in their bodies which were in all respects similar to the disease in man. Some physicians were bold enough to assert that the phenomena suggested the probability of contagion, but the notion only excited the ridicule of the profession at that period. Tuberculous disease was generally regarded as an hereditary disorder transmissible in various degrees of intensity. At the same time external influences were looked upon as powerful factors which could kindle the smouldering flame into activity. From the very dawn of modern pathology tuberculous disease received profound investigation, and the researches only corroborated the time-honoured theory. The microscope failed to detect in the diseased parts any specific elements, and in vain cells and granules, and cells of giant form were searched for some characteristic quality. Tubercle was examined by the best observers in the civilised world; thousands of clever eyes had gazed at it with intense devotion, and with a remarkable unanimity they pronounced the opinion it was so indefinite in structure that it could be recognised as much by negative as positive qualities.

In 1882 the whole pathology underwent a great revolution by the demonstration of the life-history of the tubercle bacillus. The disease, occurring in any tissue or organ, is now universally regarded as a specific disorder, the bacillus the absolute proof of its invasion, and the cause of the morbid changes. The long accepted causes are now dislodged from their position, and are rightly grouped as morbid tendencies. The inheritance of chronic inflammations, and the susceptibility to external influences, are now regarded as conditions which help the microbe to establish itself within the body. Still these factors are not less potent because the specific characters of tuberculosis have been revealed.

This pathological transformation has around it still many unsettled problems. It is, however, a fact of history that Koch, by his own researches, brought to light from the microscopic elements of tubercle a living atom which no human eye had seen before. I believe one may anticipate that this great discovery will be of priceless benefit to mankind.

Bacteriological investigation has already unfolded many of the problems connected with diphtheria. The researches began in Germany in 1882, the chief experimenters were Drs. Behring and Kitasato, and they were soon followed by Dr. Roux, of the Pasteur Institute in Paris. We now know that many animals are liable to its attacks. It is communicable to the horse, rabbit, guinea-pig, and fowl, and some species seem to suffer from a chronic form of the disease. Horses when attacked develop similar symptoms to those which follow inoculation of diphtherial toxin.

The orator insisted on the great impulse bacteriology has given to the study of the intimate connection between the diseases of mankind and the diseases of animals.

What, he asked, may we expect from this young science in the future? We are only touching the fringe of its possible revelations. Much that has been done will have to be done over again, and much that has been written will have to be rewritten. How many questions have yet to be solved? Will the further evolution of bacteriology solve the great problem concerning immunity? The striking differences in the susceptibility to disease in individuals are still unfathomed. Some seem to possess a natural insusceptibility to infectious disorders while others are susceptible on the smallest exposure. He did not believe that any individual can inherit or acquire a resisting power for all forms of disease: some races appear to acquire immunity, and native population in some parts of the world exhibit very little susceptibility to yellow fever and malaria. Race immunity is generally explained by natural selection and protection by inheritance, but we learn from experience the resisting power to infectious diseases is very variable and that there is no such thing in the world as absolute immunity.

There can be no doubt, he observed, that the pathogenic organisms are a huge factor throughout our world in the causation of disease and that we must never cease to combat the conditions in which specific organisms can grow. Still we must not forget there is always another factor which we may call feeble resisting power or impaired vitality. The susceptibility to disease bears a direct relation to the vigour of the body, and the health of every individual is the real measure of the power to resist infection. Personal immunity indeed can almost be acquired by the daily practice of temperance, cleanliness, and periodic repose.

The next subject to engage the attention of the orator was the discovery of anæsthesia and its influence on surgical practice, concluding with the remark that surgical anæsthesia can never be wholly stripped of risk, and that to-day the risk is greatly reduced by our modern safeguards and improved methods of

administration. It is certain, he added, that we have not reached finality in the matter of surgical anæsthesia, but he believed that by experience and the skilful adjustment of the dose we are entitled to regard the inhalation of our present agents as practically safe.

In regard to the future he asserted that the medical profession was never so earnest in its efforts to prevent disease as it is to-day, and it is really a fortunate thing for the world that its ranks are not getting thinner. On the other hand, the people of this country, especially the educated classes, are more anxious than ever to obtain professional assistance in the early stages of their disorders, because they are beginning to appreciate the fact that this is the best time for cure. In the near future he believed far less medicine would be taken than formerly, not, perhaps, on account of any reduction in the quantity prescribed by the faculty, but rather that people generally are growing wiser, and will trust less to mysterious and puffed-up remedies. He hoped the day would come when every vaunted specific protected by a Government stamp will carry a label revealing the exact nature of its composition.

The President next entered upon the consideration of recent advances in medicine and surgery, and concluded his address by a forecast of the role of preventive medicine in the future.

During the last fifty years, he observed, there has been a steady increase in the value of human life, and we can confidently hope that the health of the people of Great Britain will continue to improve. In the coming century a stronger and broader warfare will be carried on against preventible disease; sanitary authorities will grow in wisdom and will more graciously accept their responsibilities; the public health service will be better organised; the medical officers of health will be better paid, and wholly devoted to their duties; hospital accommodation for contagious disorders will be considerably increased; and the houses of the working classes transformed and reconstructed on modern lines. He believed there was reason to anticipate that the death-rate of the country may still be greatly reduced, and that 10 to 12 per 1,000 may be the figures of the coming century.

The great hindrance to the progress of preventive medicine which we have to overcome is the overcrowded and insanitary condition of the dwellings of the working classes. This is the field, he said, on which the great battle with infectious disorders will have to be fought out. Our warfare will not be directly with microbic life, but rather with the conditions in which specific organisms are grown. We want to see more progress in getting rid of the crowded and dirty courts in every city. We want to behold fewer of these revolting pictures of impurity and wretchedness herding together in the narrow avenues where the light of heaven strives in vain to pierce the patched and broken windows, and where the meridian beams struggle in vain to penetrate through the gloom and corruption of these denlike homes. These denlike homes are the arch-enemies of sanitary progress in all our great centres. Philanthropy has long pleaded for the removal of these great social evils; the voice of the medical profession has long sounded the alarm; but we are still waiting for the educated and wealthy classes of the community to catch the same inspiration, and to join in demanding more sweeping measures by which these nurseries of disease may be exterminated.

But the battle against disease and death will only end in disappointment unless we have something more than the force of legislation and the unceasing watchfulness of a complete sanitary system. The great mass of the people must become willing and active helpers: the fathers and mothers of our land

must learn how to maintain the healthfulness of their homes, and the blinding forces of selfishness and ignorance must be replaced by the best and purest aspirations.

If we had the power of transforming the dwelling houses throughout the land, and of establishing everywhere a perfect system of drainage, and of securing for all an abundant supply of pure water, we should accomplish but little without the help of the people themselves. The basis of national health is the personal cultivation of health. We want the fathers of England to be the enlightened sanitary officers of their own households. We desire to see a wider knowledge of the laws of health, and he hoped the day was not far distant when they will be zealously taught in every school in the kingdom.

A COUNTRY HERBALIST'S CURE FOR THE "KING'S EVIL." (a)

By JOHN KNOTT, M.A., M.D., and Dip. Stat. Med. (Univ. Dub.); M.R.C.P.I., M.R.I.A.; &c., &c.

(Continued from page 110.)

THE views of the commentators and editors of the famous "Regimen" drawn up by the medical faculty of the University of Salerno for the profitable physical instruction of Robert of Normandy, throws a good many side-lights on the pathological views held during the Dark Ages on scrofulous and allied disorders. I proceed to quote as a specimen the two lines which specially allude to strumous disease, from an edition which bears the following title:—"Schola Salernitana, sive De conservanda Valetudine Præcepta Metrica. Autore Joanne de Mediolano hactenus ignoto. Cum luculentâ et succinctâ Arnoldi Villanovani in Singula Capita Eregesi. Ex Recensione Zachariæ Sylvii Medici Roterdamensis. Cum ejusdem Prefatione. The first line, indeed, completes the notice of scrofulous disease; the second carries on the pharmacology.

"Scrofa, tumor, glandes, ficus cataplasmate cedunt, Iunge papaver ei, contracta foris tenet ossa."

These lines have been thus Anglicized—

A plaister made of Figges by some men's telling,
Is good against all Kernels, boyles, and swelling,

With Poppy joyn'd, it drawes out bones are broken,
—in the anonymous English Version published in London (1607), with the title: "The Englishman's Doctor, or The Schoole of Salerne. Or, Physicall Observations for the perfect Preserving of the Body of Man in continuall Health."

The fact that over 160 editions of this remarkable production appeared in the centuries preceding the modern literary deluge is proof positive of the immense influence which its verses must have exercised. They were addressed to Robert, Duke of Normandy, eldest son of William the Conqueror, and prepared in the Medical Faculty of the University of Salerno, the "Mater et Caput" of all the Universities and Medical Schools of Christendom.

The universal celebrity of the "Regimen" of the famous School of Salerno caused its translation into English, in the still embryonic state of that language. The resulting rare and curious black-letter gem bears the following title:—"Regimen Sanitatis Salerni. This booke teachyng all people to governe them in health is translated out of the Latine tongue into Englishe, by Thomas Paynell, which booke is amended, augmented, and diligently imprinted, 1575. Imprynted at London, by Wylliam How, for Abraham Weale." And the orthography, etymology, and syntax of pre-Shakespearean English are all thoroughly illustrated in the commentary on the first line of the above quotation, which I here reproduce:—"Here the autour saith, that plaisters made of figges are holsume againste thre diseases, yt is

to saie swines yueli, kirkels, and swellinges. By swynes euil is understand infiasion under the chynne about y^e throte. And it is called scrofula a scrofa, that is to say, a sowe or a swyne, either because this disease chaunceth manie tymes too swyne through their gulo-sitie; or els because y^e shappe of this diseases is lykened to a swyne, as Avicen sayth. By kirkels are understand impostumes, whiche commonly chaunce under y^e arme pittes, and in the groynes. And by swelling may be understande infiasions in any parte of the body. Wherefore to hele these impostumes, & specially to rype them, fygges should be sodde in water, and w^t the water shuld be mixed a little curtsy of vineger, y^e whiche helpeth y^e vertue of figges to entre. And whan it is sodde, the fygges must be beaten in a mortar: and than myngled with a courtysy of water that they were sod in, & so make a plays'er. A playster is propely medicine made of some herbe or flower, and the juyce therof: . . .

Another, more rare, more copious, and in many ways quite as interesting a black-letter volume devoted to "matters medical" had appeared even before (1558) that from which the last quotation has been made. It consists of four parts, of which the first has the following title:—"The Secrets of maister Alexis of Piemont, by him collected out of diuers excellent authors, and newly translated out of French into English. With a generall Table of all the matters conteyned in the sayde Booke. By William Warde." A good many of the "secrets" are found to consist of various modes of "cure" for the King's Evil, showing very forcibly how much the treatment of this peculiarly untractable form of disease had puzzled the wits and overtaxed the scientific attainments of both amateur and professional healers, down through all the centuries.

The first "secret" which I have selected happens to be one which I have not found in print elsewhere; and its existence in the collection of "maister Alexis" is a curious illustration of the widespread diffusion of similar popular ideas among the uninitiated of all the countries and all the ages. The item in question is a method of making an absolutely accurate differential diagnosis—a most important contribution to the knowledge of the period, when the diagnosis was generally as hazy as the treatment was doubtful.

"Howe to Knowe the Kings euill.

"Take a grounde worme alyue, and laye hym upon be swelling or sore, and couer him with a leafe: if it the the kings euill, the Worme wyll chaunge and tourne into earth, if it be not, he wyll remayne whole and sounde."

In my boyish days in the West of Ireland, I heard this method of diagnosis enunciated by an agricultural labourer, who was a relative and near neighbour of a person who practised a "cure." The only difference is that the Hibernian worm merely died at once: there was nothing said of hasty decomposition.

I now proceed to give a series of remedies culled from the pages of this very rare and very interesting volume of "Secrets":—

"A verie good easie remedie against the disease called the Kinges euill.

"Take the herbe called Farfara, Foale foote in Englishe, well stamped with his rootes, and then beeyng mingled with the flowre of the seede of Line or Flaxe, and the grease of a Barow, make thereof a plaster, and laie it upon the sore changyng it twice a daie, and all the sores of the disease shall be resolued into sweate. After thei be healed, washe often the place with white Wine, by the space of ten or fiftene daies.

"An other remedie against the same disease.

"Take the stones of an Horse, and put them in a Firepan among the embers and coles, leauyng them there, untill thei maie be beaten into pouder, then giue the Patient drink of the saied pouder in white Wine, the quantitie of twoo penie weight, continuyng this the space of xxi daies, by this meanes you shall make hym caste out at his mouthe, all the ordure, and filth of the euill, and shall heale hym thoroughly.

"A verie good remedie against the Kynges euill.

"Take Cernuse or white Leade well stamped, fower

(a) An abstract of this paper was read in the Medical Section of the Royal Academy of Medicine in Ireland on Nov. 18th, 1898.

unces, oile Oliue eight unces, let this boill together five or sixe howers, styrring it continually, and when it is waxen, or become verie blacke, it is sodden enough: then spreade it uppon a linnen clothe, and laie it unto the place of the sore: if the sores bee broken, thei will bee healed incontynente: if not, they will resolue and loose, and shortly heale throughly.

"To heale the same disease, by a substance taken at the mouth.

"Dresse a Henne as it were to eate, so that she bee boilled in a great Potte, or Caudron, with a greate deale of water without Salte, lettynge it boile untill all the bones bee separated from the fleshe, then take the saied bones, and drie them in an Oven, or at the fire, so that thei bee not burned, or waxe blacke; after this, beate them well to powder, and take of the seede of *Sesamum*, beaten well likewise into powder, and mingle it with the powder of the Hennes bones, as muche of the one as of the other. And so take a sponfull of the two powders, and mingle it with Honie, causyng the Patient to eate of it at Night, when he goeth to bedde, and in the Mornynge when he riseth. This ought to bee dooen from the beginnyng of the quarter decreasyng of the Moone, unto the ende: It is a verie excellent Secrete. It also happened to me of some menne, in whom the saied disease was so olde, and farre gone, that the saied remedie could not help them, whom I caused to take with the saied powder specified, as followe, whiche oughte to bee made after this maner. Take a certaine little Serpente called a Slowe worme, boile hym in oile Oliue, untill he be broken and consumed, then rubbe the euill with the saied oile, and laie pieces of Towe upon it, leauyng it so thre or fower daies: and after that, make a newe annointyng, and laie Towe to it againe, as before. By this saied remedie I healed them perfectly, thanks be unto God.

"To heale the Kings euil, a disease called in Latine *Seruma*.

"Take a great Tode aloue, and when the Moone draweth toward the coniunction of the sunne, cut of the legges from him, and put him about the necke of the patient, and it will doe him muche good. Take also the hoofe of an Asse and burne it, and lay it upon the sore, for it is very good and profitable for such sicknesses.

"To heale the disease called the Kings euill.

"Take Barley floure, Liquide Pitch, Waxe, and oyle of equall quantitie, mixe all together, and seeth it well, and put into it a little pisse of a yong childe, and stirring it well about, laye it upon the sore in maner and forme of a playster, and it will heale it.

"To remedie the Kings euill.

"Wash the sore and wartes with the decoction of the rinds of Caphers: then take a Serpent, and hauing cut away his head and tayle, put the other part into an Earthen pot that hath holes in the bottome, and beyng well luted both aboue and beneath, put unto it another pot as a receiver, whiche you shall cause to stande upon a pot filled with water, which shall boyle so long untill the Serpent bee dissolued into oyle, unto the whiche adding the powder of the rootes of Capers, annoynt the griefe eight daies therewith and it shall be healed.

"Against the Kings euill in children.

"Take of the iuice of Sothern wood, and of marsh Mallows, and of the Mucilage of the kernels of unripe grapes, of ech like like quantitie: lay them beyng all mixed together upon the sore. But if it be hard, dissolue in the saied iuices, of Gum Armoniack or of Bdellium, and use it as a plaister uppon the euill, and you shall see a happie successe.

"Against the Kings euill.

"Take of liquide Pitche, of waxe, of urine of children, and of meale of Barly, of ech as muche as you please: mixe them together, and putting thereunto a little oyle Oliue, laye thereof many tymes upon the griefe.

"To remedie the Kinges euill.

"Take Vitriol and put it upo the coles, and let it boyle and cast spume so long, that it become red: then braie it, and put it to dissolue in Aqua vitæ, and beyng taken

out, let it drie, and thus doe three tymes: in thende put it into a fine peece of linnen cloth and let it bang in a moist place, with a pottinger or some other recipient under it, for it will cast oile like unto oile of Tartar. Take as muche of the saied oile, as of Aqua vitæ, and bathyng therin a sponge, bind it upon the sore, and in short space it will breake it.

"To heale the Kinges euill and other harde impostumes.

"Take of Mustarde seede, of Nettle seede, of Sulphur, of the spume or fume of the sea, of Aristologia, of Bdellium, of Ammoniack, and of olde oyle, of ech like quantitie, braye all thinges that are to be brayed, and dissolue the Gummes in vinegar and make a plaister.

"To dissolue the Kings euill, and every hard impostumation.

"Take of Salt Peter one pounce, of Litarge of Siluer, as muche more, of the filthe of oyle vessels foure pounce, of Galbanum foure pound and a halfe, braye the Salt, and the Litarge, and putting thereto the filthe, bray it againe, and set it to boyle in an earthen vessell, laboring it often with a spatter, and when it doth not cleave to the fingers, take it from the fyre, and bray the Galbanum with a Pestell of wood, and meddle and dissolue them together, and being wrought upon Marble, keepe it to use when neede shall require, it will be verie marueilous."

So much for "maister Alexis of Piemont."

It is well known to all those who are acquainted with the conditions of life in the Middle Ages, that a large proportion of the practice of the healing art was then exercised by the ecclesiastical orders. In the years of monastic retirement which long preceded his elevation to the see of St. Peter, Petrus Hispanus benevolently occupied his leisure hours in the compilation of his "*Thesaurus Pauperum*," a "Poor Man's Treasury" of the most celebrated known remedies, an English version of which appeared (without date) about 1550.

A comparison of the remedies collected by "maister Alexis of Piemont," and by Petrus Hispanus, with those mentioned by Bonet, and the writer of the article in James's Dictionary, cannot fail to impress the careful observer with the hopeless thralldom to which the human intellect was subjected in presence of the incubus of "Authority" down to comparatively recent times. The authorities of Hippocrates and Galen, of Aristotle and Pliny, possessed nearly the same power to charm in the middle of the last century, that they had possessed 1,500 years before.

The same helpless and hopeless groping in the dark for relief still unattainable is illustrated in the writings of all those who have dealt with this scourge of humanity, down almost to our own times. We have seen how large a part of existing medical practice the Church appropriated in the Middle Ages; and we know that as knowledge became more widespread its more enlightened votaries did not neglect to educate themselves in the healing art. Francis Bacon tells us that he had been "puddering in physick" all his life. His successor on the throne of English philosophy, Robert Boyle, compiled a "*Collection of Choice and Safe Remedies*," many of which were intended for the King's Evil.

In common with so many of the learned men of what may, I think, be fairly called the pre-scientific centuries, the courtly and accomplished warrior and adventurer, Sir Walter Raleigh, devoted many of his leisure hours to cultivation of the theory and practice of the healing art. His "*Cordial*" long possessed a very high reputation in the healing of scrofulous and other inveterate diseases which had resisted the orthodox means employed by the licensed members of the faculty. In the very interesting little volume, "*The Court and Character of King James*, written and taken by Sir A. W., being an eye, and care witness," we are told that: "Queen Anne, that brave Princesse, was in a desperate, and beleaved, incurable Disease, whereof the Phisicians were at the furthest end of their studies to find the cause, at a Non plus for the Cure, Sir Walter Rawleigh being by his long studies an admirable Chymist, undertooke, and performed the Cure, for which he would receive no other

reward, but that her Majesty would procure that certain Lords might be sent to examine Cobham, whether he had accused Sir Walter Rawleigh of Treason at any time under his hand; the King at the Queen's request (and in Justice could do no less) sends six Lords . . . to demand of Cobham, whether he had not under his hand accused Sir Walter Rawleigh at Winchester, upon that Treason hee was Arraigned for; Cobham did protest never, nor could he; but said he, that Villaine Wade did often sollicite me, and not prevailing, got me by a trick to write my name upon a piece of white Paper; which I thinking nothing did, so that if any Charge came under my hand, it was forged by that Villaine Wade, by writing something above my hand without my consent or knowledge. These six returning to the King, made Salisbury their Spokes-man who said: Sir, my Lord Cobham hath made good all that ever he wrote or said, and this was an equivocating trick, for it was true, he made good whatever he writ, but never wrote anything to accuse Rawleigh; by which you see the baseness of these Lords, the credulity of the King, and the ruine of Sir Walter Rawleigh. I appeal now to the judgement of all the world, whether these six Lords were not the immediate Murderers of Sir W. Rawleigh and no question, shall be called to a sad account for it." If it be true, as Court gossip stated, that the malignant revenge of Salisbury was dictated by a "kind of wild justice" for the too serious practical joke which Rawleigh had played upon him in former years, and which in the end cost each his life, we have in this case one of the most striking examples that history affords of the inextricable connection between private passions and public life, between individual morality and historical pathology. Of the nature of the disease of which Salisbury was the victim, his numerous enemies, at least, professed to have no doubt, as some of the epitaphs with which they pursued their vengeance after his death clearly show. The following has been preserved by Osborne:—

"Here lies thrown, for the worms to eat,
Little Bossive Robin, that was so great,
Not Robin Goodfellow, nor Robin-Hood,
But Robin the Encloser of Hatfield Wood:
Who seem'd as sent from ugly Fate,
To spoil the Prince and rob the State.
Owning a Mind of dismal ends,
As Traps for Foes, and Tricks for Friends.
But now in Hatfield lies the Fox
Who stank while he liv'd, and died of the —.

Others among his detractors announced that he died of the "Herodian disease," while his apologists aver that he perished as a victim "of a complication of disorders operating on a scorbutic habit of body."

The constituents of Rawleighs cordial have been preserved for us in a remarkable eulogistic commentary, written by a French scientist of the period. For the benefit of the curious it is here reproduced:—

"*Recipe* Rasuræ Corni Cervi libram unam; Carnis viperarum cum Cordibus & Hepatibus uncias sex; Florum Boraginis, Buglossæ, Roris Marini, Calendulæ, Vetonice Coronariæ rubræ, Roris Solis, Rosarum rubrarum, & Sambuci, singulorum libram semissem; Herbarum Scordii, Cardui benedicti, Melissæ, Dictamni Cretici, Menthæ, Majoranæ, Betonicæ, singulorum manipulos duodecim; Granorum Kermes recenter in rob redactorum, Cubebarum, Cardamomi majoris, Baccarum Juniperi, Maceris, Nucis myrticæ, Caryophyllorum, Croci, singulorum uncias duas; Cinnamomi acutissimi, corticis ligni Sassafras, flavidinis malorum Citriorum & Aurantiorum, singulorum uncias tres; Lignorum Aloës & Sassafras uniuscujusque uncias sex; Radicum Angelicæ, Valerianæ, Carlinæ, Fraxinellæ seu Dictamni albi, Serpentariæ Virginianæ, Zedoariæ, Tormentillæ, Bistortæ Aristolochiæ longæ, rotundæ & cavæ, Gentianæ & Imperatoris, singulorum unciam unam & semissem. Omnia incisa & grosso modo contusa in vasi idoneo posita cum Spiritu Vini rectificato extrahantur secundum Artem. Tincturæ filtratæ in extractum mediantes, in Mariæ balneo, distillatione evaporentur, Magma expressum comburatur; Cineres reverberati per aquam elixivientur, unde Sal purum lege Artis paretur, quod Extracto

miscetur. His ita peractis, huic Extracto adde, ut Artis est, Pulverem sequentem ceteraque ingredientia. *Recipe* Lapidum Bezoardicorum orientalium et occidentaliū verorum uniuscujusque unciam simissem, Magisterii solubilis Pelarum orientalium uncias duas, Magisterii solubilis Corallorum rubrorum uncias tres; Boli orientalis, Terræ Sigillatæ veræ, Unicornu mineralis, Cornu Cervi Philosophicæ præparati, & Cornu Cervi calcinati, singulorum unciam unam; Ambre griseæ electissimæ in Essentiam redactæ unciam unam; Moschi orientalis optimi essentificati drachmam unam & semissem; Croci Solis cum tinctura Antimonii Basilii Valentini parati drachmas duas; Sacchari candidati albi subtilissimè pulverisati libras duas Ex his omnibus mixtis & ex Arte unitis fiat confectio verè Regia, quæ ad usum reservetur in pyxidibus apprime clausis."

Whatever opinion we may form in the present day of the therapeutic value of this elaborate formula, it can hardly be denied that there is something to admire in the studious attention which the gay and gallant Sir Walter must have bestowed upon its preparation.

The famous "Brevaire of Health" of Andrew Boorde—the "Merry Andrew of Physicians," *Andreas Perforatus* of his own periods of comic dignity—contains but one short chapter on the subject, and his method of dealing with the condition reminds me forcibly of the time-serving policy of John of Gaddesden, to be afterwards referred to.

"The 236 Chapter doth show of the Kings euill.—" *Morbis regius* be y^e Latin words. In English it is named the kings euill, which is an euill sicknesse or impediment.

"THE CAUSE OF THIS IMPEDIMENT.

"This impediment doth come of the corruption of humours, reflecting more to a perticular place than to universall places, & it is much like to a fistle, for and if it bee made whole in one place it will break out in an other place.

"A REMEDY.

"For this matter let every man make friends to the king's maiestie, for it doth pertain to a king to help this infirmitie, by the grace ye which is giuen to a king aynoynted. But for as much as some men doth iudge diuers tymes a fistle or a French pocke to bee the kings euill, in such matters it beehoueth not a king to meddle withall, except it be thorow & of his bountifull goodnesse to give his pitifull and gracious counsell. For kings and kings sonnes and other noble men hath beene eximious Phisicians, as it appeereth more largely in the Introduction of Knowledge, a book of my making."

As our author enjoyed what some of us would probably consider the uneasy dignity of physician to his Majesty King Henry VIII., we can appreciate the discretion which dictated the remedial diplomacy recommended in this chapter. It may not be uninteresting to mention in this connection that the "Brevaire" from which the above quotation has been taken is said to be the first manual composed in English by one of the Faculty.

(To be concluded in our next.)

The Nursing Problem.

NURSES OF THE LATEST FASHION.

A.D. 1899.

PROFESSIONAL EXPERIENCES IN SHORT STORIES.

By FREDERICK JAMES GANT, F.R.C.S.,

Consulting Surgeon to the Royal Free Hospital.

II. — THE HUSBAND-HUNTRESS AND TRAPPER-NURSE.

IN contrasted alliance with the inhuman species of woman, Satan in Petticoats, who is the exponent of the latest possibilities of nurse or nurse-attendant—I now introduce the reader to one who is morally very unfit or a heaven-born calling, and socially a very dangerous

type of feminine nature, gaining admission into families—as a nurse, for the exercise of her art. That such is the way of the world with either sex, does not ennoble and beautify the character of one who plays her part under cover of a dress and vocation which specially offer opportunities for her purpose.

See yonder sick and suffering wife; her husband in daily intercourse with Nurse Lovibond; she readily and rightly wins the heartfelt gratitude of him who sees in her ever-watchful attention and devoted care, on behalf of the sufferer, all the qualities of that womanhood which has blessed his own life, she who might replace a mother to his young children. Or, the only son of his mother—a widow, is attracted by the fidelity and womanly grace of one who nursed her in her lingering last illness—a vision of the woman who would share his fleeting joys of sunshine, support him in tempest-tossed hours of adversity, dispel the clouds of sorrow—in the loss perhaps of love's pledges, in sickness, God's Nurse-messenger; and forsaking all other, keep only unto him, until she receded from his longing eyes and holden hand to reappear in his first consciousness beyond the veil. In either of these cases, say you, what a divine union with father, or son. Surely some such women, by their natural endowments and life-training, are the truest of Eve's daughters, and have proved themselves the best wives. I am certain that no such woman, in the vocation of a nurse, would be a disguised husband-hunter and trapper.

In a villa on the wild and weird coast of Tenby, in North Wales, a palsy-stricken lady rested during the last few years of her troubled way, with nothing true about her but the first beams of heavenly light in her soul, and a daughter of comfort and consolation. Husband, not a deserter, but absent by private "deed of separation;" an only son, a drunken sot, &c., occasionally visited his invalid mother.

To be accurate with regard to their relationships, I may mention that the son was his father's, Mr. Goatman's stepson, by his wife's former marriage. Mrs. Goatman, who was divorced from her (previous) husband in exceptionally painful circumstances, readily consented to her son's exchange of surname, which would thus to all the world conceal a wretched, a hideous past.

Her (present) husband, Mr. Goatman, as a stock-jobber, usurious money-lender, and bubble-company promoter, had amassed a large fortune, increased by building investments, &c. He well knew how to keep that which he had thus gathered, without indulging his generosity for the benefit of others, apart from self-gratification as his motive.

If the love of money be the root of all evil, in the soul, this passion would seem to be soul-destroying by first enthroning self, as the idol of worship, with all the mind, with all the heart, and with all the strength of the moral nature; extinguishing the love of self-sacrifice for others, as the true source and sustenance of the higher life, whereby, whomsoever will lose his life shall find it; and he who would keep his life, shall lose it. Thus had the greed for money killed the soul of its victim in the person of Mr. Goatman, the embodiment of selfishness.

In an illness prolonged and tedious, passing into a pathetic imbecility, nurse-attendants on his poor wife came and went in succession. But the last such attendant, Nurse Lovibond, eclipsed all the previous, sisters in her ministrations; for as they paid attention only to the wants of the restless invalid, our Nurse Nonpareil found time to extend her favours to one other, the witless boy-stepson, who despite his personal demerits, possessed an overpowering attraction to her, money.

A young lady, tall, tender-eyed, and otherwise personally well-favoured, and equipped with more than the average of woman's sail, and bottom-ballast of steadiness, would surely capture the ever-floundering craft of a young man who could never pull an oar, or steer his course in life, when pursued by a clever and experienced adventurer on the same ocean.

In the person of our present adventuress, it must be admitted that her methods were refined and delicate; all the more engaging to a young man who could the

better appreciate a tone of character he did not himself possess. It is thus that the lowest and most depraved moral nature often experiences the refining influences of companionship and conversation, which the reading of healthy books would fail to impart. Character begets and moulds character by association. The drama teaches, not only by studying the pages which portray human life in its highest forms of virtue, or would correct vice in its unloveliness and repulsiveness; all the *dramatis personæ* must act and speak for themselves, as in life, to really and fully convey the lessons which the dramatist would teach. Even Shakespeare's most living creations of character are dead-liveless forms, as seen only in the plays he wrote; until vivified by the true actor's art, they speak and move on the stage. Thus it is, that Hamlet, Othello, Macbeth, Lear, with the accompanying types of feminine character, fulfil the teaching purposes of the Drama, when rightly interpreted and impersonated. To return from this digression.

Mr. Alfred Goatman (fils) and Nurse Lovibond are sitting closely coupled together on a rock, under the cliff, at Tenby, and as the lady draws thoughtless figures on the sand with the point of a sunshade, she pours her domestic history of pitiful privations and troubles into the ear of a sympathetic listener. A few sea-gulls perched on recesses in the adjoining cliff, or flapping their wings around the happy pair are the only other depositories of her moving tale; and of his response whose heart was open to distresses, which in idle affluent circumstances he had never known.

Mr. Alfred, however, is a man with a past. His marriage with a barmaid, undiscovered for a while by stepfather and the mother of her darling boy, was nevertheless, in due time blessed by the birth of a girl-baby, then a boy was born; both of whose characters, as they grew, have thus far done much to redeem an unhappy legal union.

We have now reached the stage at which fair Nurse Lovibond has hooked and landed Mr. Alfred; but it was not long before accident apprised her of his much married past.

The announcement that Mr. Alfred was a married man having been made by letter by the lady-nurse who had caught him of the music-hall species, he was interviewed by the fair trapper. He coolly admitted the impeachment—simply remarking—"don't I look like a married man"; a rather mortifying challenge of the trapper's skill; who at once let him escape to enjoy his married liberty and felicity.

Nurse Lovibond resumed her duties of attendance on the old invalid lady with more singleness of purpose, now that she was no longer pre-occupied with the all-absorbing designs of captivating and capturing Mr. Alfred. She performed her duty more efficiently and faithfully when freed from the distraction of her former pursuit to find a man suitable at least for her purpose in marriage; who, whatever his personal qualification and social position might be, would be provided with a certain "settlement" on her in this uncertain life.

As the end of the case drew near for the poor wife's release from long suffering, and the blighted faith of years, let us hope and believe that some restoration of conjugal affection and respect for manhood were felt by the departing spirit; that some words of reconciliation passed between her and her husband, and that some lost appreciation of a truly good woman, wife and mother, awakened Mr. Goatman's dead soul, and somewhat redeemed his grievous errors in the past.

Our lady-nurse in the loss of her patient, loses also her situation. But she bears—it seems—a good character for faithful attendance and kind attention, and of having such knowledge as an "untrained" nurse may have casually acquired. Cast upon the world to find her own way, and in her own way, she was not long in making, as she thought, a good venture. She would rent of Mr. Goatman the pretty and well-furnished residence in which his wife had died and convert it into a small sanatorium for invalid ladies and gentlemen. The air of Tenby is, perhaps, more generally salubrious than the climate of the Riviera. Mr. Goatman, with his large fortune, gladly let, at a nominal rental, a villa which recalled to him no happy memories.

In her new enterprise, the lady-nurse tenant, associated with her own disqualifications, the "trained" qualifications of a younger sister—a "certificated" nurse. Not unlike in personal attractions, the two young ladies were bound to each other by a strong sisterly affection; but, differing in the inner woman, Nurse E. Lovibond shared not her sister's craft and design; under cover of her nursing vocation, she would have scorned to captivate and capture any man in marriage. The elder sister—of whom we have yet to know more—had started her sanatorium with a double prescience; the possibility of its failure as a business speculation, and an ulterior view in that event.

At the end of a year the landlord, not seemingly a hard-hearted man, as he had shown himself at his wife's grave, was unwilling to allow the fourth quarter to pass over without any payment—for business with him meant business, and he then gently reminded his fair tenant of her forgetfulness. She frankly confessed the failure of her enterprise, invalids coming and going, or leaving the place empty, as in other such resorts; but Nurse Lovibond would willingly work out her rent in some other way. Old Mr. Goatman had occasionally visited the sanatorium during the year, and had seen and admired the younger sister no less in view of her personal outfit, than that he saw in her also a woman to his taste as a business man—steady, and with singleness of purpose; as compared with the flippant, coquettish, love-making elder sister.

Mr. Goatman felt a sincere sympathy for the younger sister in the distressful failure of her efforts to make the sanatorium a success; and to cut short any description of his prosaic proposal to relieve her anxiety as to what her future might be—he plainly proposed to offer her a home as his wife! The landlord-widower would thus cancel her sister's debt due to him as rent. In these circumstances the younger sister reluctantly accepted the offer of a new way to pay a heavy debt, which assuredly the rich landlord would not otherwise have cancelled, than by having his "pound of (her) fair flesh."

Meanwhile, the elder sister had not forgotten her resource in the event of the sanatorium proving to be a financial failure. In an interview with the landlord, she proposed to him her method of paying the rent, without incurring any further liability. She had heard that Mr. Goatman was in quest of a housekeeper; and she at once offered her service in that capacity. Her failure had not been owing to any ignorance of housekeeping; the sanatorium had not answered as a health resort. She had full confidence in her ability to conduct the internal arrangements of Mr. Goatman's large establishment at "Emby. What might be Nurse Lovibond's ulterior view in making this proposal, the reader of this story will shrewdly and surely guess.

In the final interview of Nurse Lovibond with Mr. Goatman, he would have accepted her proposal to work out her rent—when she again pressed upon him her service—as his housekeeper. But, said he, "there is just this difficulty; I am about to marry your sister, and it would hardly do for me to have you in my service, with your sister as my wife." Alas, the poor husband-trapper was foiled a second time, after her first adventure with Mr. Alfred G., the stepson; caught again in her own trap.

Of course, she never again tried to establish a sanatorium. She returned to private practice. I have heard that she married a young doctor which would take her out of practice; I cannot credit the report; for although I believe some doctors have found wives in nurses and good wives; it would be incredible that any man having any knowledge of nurses, would himself select one of Nurse Lovibond's species, or have been caught by her in marriage.

What may have been all the aptitudes which Nurse Lovibond possessed cannot be fully and fairly estimated, in addition to her personal gifts, which doubtless surpassed her qualifications, as an "uncertificated" nurse. She moved among the wealthier classes of society—or as she expressed it—in good families. But, unfortunately, the public of that world more especially, cannot distinguish between the true and the false species

of nurse; while the personal gifts which society might value most—in charms of appearance, manner, and conversation, are often such as would least qualify a woman to honourably, not to say religiously, fulfil her duties. Of strictly technical qualifications, the public can hardly be expected to know anything—nor of the Nurse Lovibond species.

Clinical Records.

WESTMINSTER HOSPITAL.

Two Cases of Fatal General Phagedæna.

Under the care of Mr. WALTER G. SPENCER, M.B.Lond., F.R.C.S.,

Surgeon to the Hospital.

CASE I. was that of an unmarried man, æt. 61, who had not drunk excessively, and in whom evidence of syphilis was limited to a superficial ulceration of one eyelid. The disease had been inoculated a week before and gangrene had extended to the external genitals, perineum and lower part of the abdomen, as well as perforating the anterior wall of the rectum. The gangrenous parts were removed and strong antiseptics used with the result that healthy granulations covered the whole surface, and recovery seemed almost possible, when slight signs of broncho-pneumonia appeared, and the patient died on the tenth day, 2½ weeks from the date of infection. No other disease was noted.

Case II. was that of a woman, æt. 35, who had had years before pelvic inflammation of venereal origin, but for the previous year had felt quite well. A fortnight before admission signs of severe pelvic inflammation reappeared, with a foul blood-stained vaginal discharge. During a month in hospital the vaginal discharge became less, and she was then operated for double pyosalpinx by laparotomy. Owing to dense pelvic induration and adhesions, the whole of the distended tubes could not be removed. Extremely foul pus escaped. The pelvis was plugged with gauze. For the first week the patient did well, only a little foul discharge escaping. Then menstruation, which had been absent beforehand, came on, the pelvic inflammation lighted up, and the abdominal wound, which had previously been healing, was infected from within, and each gaping surface was found to be covered with phagedæna. By vigorous treatment this was arrested on the surface, but progressed in the pelvis until the small intestines were perforated, and fæces were freely discharged for the last two days. The patient died on the fifteenth day after the operation. The phagedænic process had extended to the uterus, but not to the vagina. The coils of intestine in contact with the pelvis and abdominal wound had been invaded. The rest of the peritoneal cavity was free, and no other disease was found post-mortem.

Mr. Spencer finally referred to the progress which had been made in connecting phagedæna with the presence of a peculiar bacillus.

Annual Meeting of British Medical Association,

HELD AT

PORTSMOUTH, AUGUST, 1899.

THE ANNUAL EXHIBITION.

THE annual exhibition was held in the Drill Hall at Portsmouth. It was well up to the average so far as exhibitors and exhibits were concerned, but the attendance of members was decidedly small. This falling-off was probably due to the heat of the weather and the host of attractions that claimed attention elsewhere. But whatever the reason, the contrast between the numbers that were to be seen at Portsmouth and at the corresponding show in Edinburgh last year was, to say the least of it, conspicuous. Appended will be found brief

notices of the more important exhibits, all of which have already become familiar to readers of the *MEDICAL PRESS AND CIRCULAR* through the medium of our advertisement columns.

THE ENTERTAINMENT.

Whatever view may be taken as to the general organisation, and the sectional work, at the Portsmouth meeting, there can be no doubt whatever as to the success of the recreational side of the affair. The excursions were numerous, most interesting, and, on the whole, exceedingly well organised. The most brilliant reception was the ball given by the Mayor (Alderman Scott Foster) and Mayoress, on Friday night, at the Town Hall. That magnificent building was brilliantly decorated and illuminated, both inside and out. The effect of the broad facade of steps in front of the building and the high relief lent by the electric lighting to its lofty pillars was one of the most striking and artistic that could have been conceived. Dancing was kept up to a late hour, and the guests, including a number of townfolk, were entertained at supper in a large marquee erected behind the hall. The hospitality of the Mayor of Portsmouth certainly eclipsed that shown at the average of association meetings, not only in the scale of generosity but in attention to the minutest details of organisation. Those of the members who stayed over Saturday had the opportunity of witnessing a "Tattoo" by the massed bands of the garrison. The effect of the torchlight marchings, and of the bicycle evolutions, relieved by a brilliant display of fireworks in the illuminated grounds, formed what may be described, without exaggeration, as a gorgeous military spectacle. Space does not permit any detailed description of the rest of the entertainments.

THE PATHOLOGICAL MUSEUM.

The two chief features of the scientific museum may be summed up in the phrases, gunshot wounds and Röntgen photographs. A large and varied collection of bones injured by bullets was sent from the Royal Naval Hospital at Haslar and the Army Hospital at Netley. In it were shown almost every conceivable injury of bone, immediate and remote, dependent on missiles, to say nothing of injuries to soft tissues. These two hospitals contributed between them no less than 189 specimens of first excellence. The London Hospital Medical College was represented by a neat collection of up-to-date anatomical and pathological specimens. The Leeds Medical School sent an interesting case of specimens, especially of some renal tumours. Mr. L. V. Cargill exhibited some excellent specimens of pathological eyes, mounted in glycerine jelly. Mr. Jonathan Hutchinson, jun., had a number of interesting surgical specimens, and of radiograms, amongst which may be specially noted the photograph of separation of lower epiphyses of femur, and a sub-coracoid dislocation of the shoulder before and after reduction. Mr. Mackenzie Davidson showed stereoscopic views of much beauty and interest. One of the upper thoracic skeletons reproduced the cancellous tissue of the numerous and other bones in striking perspective relief. He showed eight cases of calculus. Professor Stevenson, of Netley, had a good stereoscopic view of a buckle buried in the tissues by the impact of a bullet. Mr. Hugh Walsham had a series of good photographs of pathological conditions of the lungs and heart, and an excellent one of a renal stone, both *in situ*, and after removal. Mr. H. A. Boone showed some interesting X ray records, including various badly united fractures, and a subluxation of the knee by the kick of a horse. Dr. David Walsh showed a chest with sharply defined miliary tubercles, scattered through the lungs—a record of a tumour apparently connected with the kidney in a tall stout woman, possibly of an hydatid origin; absent clavicles, fractured ribs, and a hæmophylic knee. There was a most valuable and interesting collection of ancient medical books from Netley, which also sent numerous radiograms of gunshot injuries. Dr. Claremont showed some good pathological specimens, and Dr. J. Eyres

exhibited some water-colour sketches of tuberculosis of the conjunctiva.

THE MUSEUM.

The SANITAS stall was filled with its usual display, including the Ringzett sulphur fumigating candles, Local Government Board corrosive sublimate pellets and an imposing array of Sanitas preparations. Sanitas wool of excellent quality was exhibited, and from personal experience we are able to testify to the excellences of this particular preparation. Sanitas soap is another article that will repay a trial. A special preparation is the peroxide of hydrogen. Ringzett's patent, a stable article which it is claimed, does not deteriorate after opening the bottle, and is not decomposed by light. The bronchitis kettle for the use of Sanitas vapour is so familiar an article now in the sick-room that there is no need to enter into a detailed description of its excellences. A similar remark applies to other well-known productions of this enterprising firm.

The FORMALIN COMPANY has this year introduced a powder containing the active antiseptic in a potent and convenient form. The alformant lamps in the different A and B shapes were shown, and the later form, which is on the principle of a water bath. Grutol is a gelatinous preparation of formalin intended for the treatment of wounds. At body heat the antiseptic is slowly liberated and acts on the tissues. A fine spray is also provided, the working part being a metal atomiser of showy but simple construction. A scented preparation of most agreeable nature is provided for general purposes about rooms. Formalin is also put up in bottles for household use.

Messrs. PARKE, DAVIS & Co. showed all their usual preparations, such as liquor sedans, euthymol, syrup of hæmatic hypophosphites, and vakadiastase. Among the newer things was a fine line of chocolate-coated tablets, including nearly two hundred varieties of drugs and combinations of drugs. These practically replace in a pleasant and palatable form the old-fashioned pills and powders, and are quite in accordance with the modern tendency to elegant pharmacy.

Our attention was particularly arrested by senna cordial, an elegant elixir of that standard aperient. Its chief characteristic was a pleasant taste of figs. The throat mentholated tablet is a good voice and throat lozenge, specially suitable for singers and speakers. It contains menthol, cocaine, benzoic acid and other drugs, and has the advantage of being perfectly safe. We should mention the excellent work done by this firm in the direction of the physiological standardisation of those drugs not capable of chemical assay, such as ergot, strophanthus, digitalis, and cannabis indica. These preparations deserve the confidence of the medical profession. Another point is their serum preparations, which are supplied in the familiar hermetically-sealed bulbs that have been from the first adopted by this firm. They include the antistreptococcic, antitetanic, antidiphtheritic serums, with Coley's fluid, mallein and tuberculin, and are carefully tested and standardised.

Messrs. BAYER and Co. had an exceedingly artistic stall. The covering, a delicate shade of olive green embroidered with various devices, and fringed with a most tasteful edging of raised and stamped scroll-work of faint maroon colour, twined with green velvet leaves. On the stall itself were conspicuously placed several oval shie'ds, the borders of which were fashioned into raised pattern, with an effective bay-leaf and berry ornament made of several kinds of differently coloured metals. The upper part of the stall was draped in a delicate plush of an artistic tint, which it would be difficult to name, but which with its iridescent shades formed a perfect contrast from the pale olive green of the main motive. The principal exhibits are too well known to need detailed mention, for such drugs as phenacetin, sulphonal, trional, and lycetol are household words in the therapeutic world. Among the newer productions are asperin, a substitute for salicylic acid, which claims to avoid the disadvantage of the latter, and heroin, the newest and most effectual derivative of morphine, with its soluble salt, hydrochloride of heroin, the latter

intended especially for hypodermic use. Heroin does not constipate, and is less toxic generally than morphine. Protargol, as everyone knows, is a combination of silver with a proteid substance. It contains about 8½ per cent. of silver, and unlike other silver compounds, it is unirritating, and, at the same time, very penetrating.

Tannigen and Tannophen for use in enteritis; two intestinal antiseptics that have lately attracted a good deal of attention. Tannigen is a triacetyl of tannin and tannophen, a combination of tannin with urotropin. Trional and lycetol are both prepared as oxycarbonate waters by Messrs. COOPER, of Gloucester Road, London. This is an excellent method of administration under the pleasant guise of an aerated water.

THE BRITISH SOMATOSE COMPANY, LTD., of 165, Queen Victoria Street, who now possess the sole selling rights of somatose, make an exhibit of their three well-known preparations, somatose, iron somatose, and milk somatose.

THE HUNYADI JANOS water had a handsome stall in a commanding position just opposite the entrance. The pyramids of differently sized bottles decorated with the familiar red labels, had a remarkably good effect. The sales of this excellent water, we are glad to learn, have advanced of recent years to high-water mark, and testify to the high appreciation of the medical profession and of the public. There is no need to descant upon the virtues of this, perhaps the most popular of all natural aperient waters. Its merits are established on a sufficiently firm basis to secure their lasting fame.

NEWBURY AND SONS had a varied assortment of drugs. Their exhibit, as usual, was especially strong in sugar-coated pills of many different formulæ. A special feature was the preparations of sumbul, a heart tonic used in hysteria and other conditions. This was put up in pill form, and also as a liquid in tono-sumbul. Bromo-soda, an effervescing nerve tonic and calnative, was conspicuous, and also a number of other elegant pharmaceutical products of Messrs. WARNER AND CO., Philadelphia, for which firm Newbery and Sons are the agents. A special note should be made of the effervescing lithia tablets for use in gouty conditions. A portable and sterilisable hypodermic syringe with metal plunger appeared to be excellent in type and construction, besides being of moderate cost.

MELLIN'S food and other preparations were strongly in evidence on a most artistic-looking stall. The food for invalids and infants is so well known that it need not be more than mentioned. It may be added, however, for the benefit of those who admire the older product that Mellin's food biscuits are prepared largely from that material. They are specially recommended for use in childhood. The cod-liver emulsion claims special attention from the fact that it is the only 50 per cent. emulsion on the market, and is rendered agreeable to the palate by a cinnamon flavour, and is to be recommended in all cases of phthisis and other disease of malnutrition. Blended with Mellin's food it is said to make a good malted emulsion. A number of attractive little souvenirs were distributed to visitors.

THE APOLLINARIS CO., LTD., had a show of the various waters which form their specialties. Apenta, as everyone knows, is a natural aperient water that has come into vogue within recent years. Its chemical composition is such that it stimulates the gastro-intestinal tract without causing irritation. Another important point is that it contains lithium. The Johannis lithia and Johannis potash, are two new waters, the nature of which is sufficiently indicated by the names. They are both composed of additions of lithia and of potash to the Johannis natural sparkling water. With a little ingenuity in the direction of flavouring agents, it is possible, with the aid of these admirable waters, to administer remedies in a pleasant and indeed an almost imperceptible manner. Apollinaris needs only to be mentioned as the Queen of Table Waters.

BRAND & CO., Mayfair, showed their well-known products on a neatly arranged stall. Prominence was naturally given to their meat juice, which is ready for immediate use and cheaper than most preparations of the kind. The analysis is satisfactory, and it is guaranteed to be made from the finest English beef. A

new preparation of this firm is the "Nutriment Powder," made from raw meat deprived of its natural moisture. It can be taken in a sandwich or in water or wine, in both of which it is partly soluble. The chief advantage of this new product is that the nutrient qualities of the meat are retained in an almost tasteless and odourless form. There is also a special "fever" food for use specially in the tropics. It contains essence of beef, cream, and egg. Altogether, the exhibit was quite worthy of the representation of the firm.

MESSRS. NESTLE had a handsome show of their special products. The well-known children's food, and the Viking brand of unsweetened milk; as everyone knows the latter contains milk and cream without sugar. It keeps well, and is palatable. Samples of milk and soda water were freely dispensed at this stall, and the firm also endeavoured further to assuage the tropical heat that prevailed in the exhibition hall by distributing Japanese fans to visitors, who availed themselves widely of these timely gifts.

MR. B. KUHN exhibited an imposing array of special preparations, of which the popular and efficient antiseptic, Chinosol, was the most conspicuous. This drug, as all surgeons know, is non-poisonous, non-corrosive, and a powerful deodorant and germicide. It is put up in tablets, dressings, dusting powder, and other forms convenient for surgical purposes; and is, furthermore, adapted for veterinary practice, for hygienic and toilet purposes, and for general sanitation. Other preparations of this firm include argentol, vannalbin-knoll, diuretin-knoll, colchi sal capsules, betul ol, and papain finkler, the special properties of which need not be entered into here. A large number of the articles on show cannot be mentioned here, but in conclusion note may be made of the ethyl-chloride glass bulbs.

France.

[FROM OUR OWN CORRESPONDENT.]

PARIS, August 5th, 1899.

MYOCARDITIS.

At the Medical Congress held at Lille last week, M. Huchend read a paper on the different forms of myocarditis. He said that one should be on guard against the present tendency of diagnosing myocarditis where it did not in reality exist. Simple troubles in the innervation of the heart, disturbance of the cardiac rhythm of reflex order, modifications in the arterial tension, auriculo-ventricular thrombosis could lead the inexperienced to suppose the existence of myocarditis in the course of such infectious maladies as typhoid fever or influenza. But if abuse was frequently made of the term of acute myocarditis the study of the chronic form was generally overlooked and gave rise to errors of considerable importance.

Taken in the true sense of the word, myocarditis means inflammation or myositis of the cardiac muscle. When a microbe or a toxin penetrate into the substance of a tissue, their action, if sufficiently energetic, operated the destruction of the anatomical elements by cellular necrobiosis. The dead cell became a thorn in the side of the perenchyme: it was then that inflammation intervened to remove from the organism the foreign body. In acute myocarditis the inflammation constituted, consequently, but a secondary or transiting phenomenon the same might be said of chronic myocarditis. Thus all the lesions which served to classify chronic myocarditis (interstitial modifications, sclerous condition, fatty degeneration, segmentation of

the cardiac fibre) had frequently but the name of inflammation. Forgetting the extreme rarity of muscular inflammation, abuse was made of the word myocarditis to include every degeneration of the fibre of the cardiac muscle. All cases of chronic myocarditis comprised in different proportions, lesions of the interstitial tissue, parenchymatous alterations, and vascular lesions, but different pathological conditions of the myocardia, presented particular characteristics which required a special description.

Sclerosis in patches or arteriosclerosis of the heart was characterised by degenerative lesions occupying the territory of a stenosed artery, and ending in dystrophic sclerosis, the ultimate term of a trouble of nutrition due to ischemia. Those patches might be very small and disseminated, consequently stricture of the coronary arteries should be sought for. If those patches interested a large extent of the walls of the heart, a large vessel had been obliterated. In such case, the heart, voluminous, assumes a globular form. General dilatation of the ventricle, or partial dilatation (aneurism of the heart) might result. At the seat of the sclerosis there was always to be found atrophy of the wall, frequently resulting in rupture of the heart.

In diffuse sclerosis, chronic interstitial myocarditis, rings of sclerosis surround directly the artery, and progress in destroying the cardiac fibres; the arteries were not the seat of obliterating endoarteritis, but rather that of irritation of the peri artery, terminating in thickness of the vessel. The microscopic appearance of the heart was also different, the organ frequently enormous, and kept its conical form without dilatation of the cavities or atrophy of the wall.

Senile sclerosis was the terminal point of cardiac lesions exclusively provoked by the progressive disintegration of the elements of the organ by reason of the advanced age of the individual. The cardiac fibre underwent senile atrophy, whilst the fibrilla of the conjunctive tissue took its place to fill the empty spaces.

Three principal clinical forms of cardiosclerosis might be admitted—painful or cardiac stenosis, arhythmic and tachycardia, myovalvulaire. The arhythmic form was characterised either by intermittent attacks of arrhythmia or by a sort of cardiac folly which could persist six, ten, or even fifteen years as the only symptom. It was generally unaffected by digitalis. In the myovalvular, type a scuffle of insufficiency of the orifice could be heard due to sclero atheroma of the valve.

A phenomenon appearing generally at the *début* of arterial cardiopathy was the toxi-alimentary dyspnoea. That dyspnoea proved the existence of renal insufficiency even in the absence of albumine, and yielded to milk and vegetable diet. Death in arterio-sclerosis of the heart could be sudden, by syncope or by angina pectoris. It could be rapid either from rupture of the aneurysm of one of the coronary arteries in the pericardium or from rupture of the heart itself, or it might result from acute oedema of the lungs, uremic trouble, hemorrhage, or cerebral softening. On the contrary, the fatal termination might arrive slowly by asystolia, cardiac thrombosis, or from arterial cachexia, characterised by general emaciation and pallor of the face.

As to the treatment of cardiac sclerosis, the fundamental principle was to ease the organ by attenuating the peripheric resistances. Diuretic drinks, notably

milk and certain mineral waters, should be prescribed, while tea, coffee, liquors, pure wine, should be suppressed. Aliments containing a great deal of ptomaines, meat, preserves, fish, cheese, &c., should be forbidden. Abuse should not be made of drugs; theobromine was an excellent diuretic, while saline purgatives might be given with advantage. As a vaso-dilator nitro-glycerine rendered good services given in solution (1 per cent.) during twenty days a month in increasing doses of from 4 to 20 drops daily. During the remaining ten days of the month iodide of sodium might be prescribed.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, August 4th, 1899.

At the Medical Congress Hr. Krönig, Berlin, reported on

LUMBAR PUNCTURE.

which in some cases had led to very interesting diagnostic conclusions. With a very delicate apparatus he had investigated as to pressure in fourteen healthy men, and had ascertained that in the horizontal lateral posture the pressure was 125 mm., in the upright 410 and that the physiological range in the horizontal side position was between 100 and 150 mm., that in the sitting posture between 300 and 450, that in the horizontal side position the fluid exuded drop by drop; but that in the sitting posture it flowed in a stream. He was able to confirm Quincke's statement, that in the healthy individual the microscopical elements consisted of a few lymph corpuscles, with individual red blood corpuscles. The question as to whether there was a serous meningitis or whether such supposed cases were really simple hyperæmia with oedema was still debatable. Among other cases he had examined two of typhoid with cerebral symptoms from which a simultaneous serous meningitis might have been suspected. He found high pressure, but extraordinarily few cells, and those of a normal character. An autopsy was made in one case, and nothing but pronounced hyperæmia and oedema were found, and microscopical examination showed no trace of inflammatory serous infiltration. In two cases of chlorosis the speaker found pronounced capillary oedema, a few lymphocytes, and here and there an endothel. In a case of diabetic coma nothing was found beyond hyperæmia and oedema. In acute serous meningitis the same was found as in acute serous pleuritis, viz., only lymphocytes.

Polynuclear elements were scarcely ever found; occasionally there were apparently polynuclear elements produced by fragmentation of lymphatic nuclei. He had come across the chronic form of serous meningitis in various ways. His histological investigations were only positive when there were distinct oscillations in the tube of the manometer, as the oscillation showed that the communications between the brain and the cord were perfect, and the condition of the fluid withdrawn was an illustration of the condition of both cavities. If nothing was found in the spinal fluid, then nothing would be found in the cerebro-spinal fluid. If there were no oscillations it showed that connective tissue was present, preventing the pulsation of the basal arteries being passed on downwards, and in

such a case the fluid in the brain might be different from that in the spinal cavity.

In 4 cases there was proof of softened cerebral substance in the spinal fluid.

The oscillations in the tube in the case of healthy individuals were 2 to 5 mm. With a weak radial pulse only weak oscillation were to be expected. If excessive oscillations were met with with a weak radial pulse this would be due to strong pulsation of the basal arteries. In such a case his diagnosis would be either pulsating tumour or aneurysm. The pulsation oscillation with great significance in the case of cerebral tumour.

At the Society for Innere Medizin, Hr. Litten showed preparations of

CYSTIC KIDNEY AND CYSTIC LIVER.

They were taken from a woman æt. 55, who 10 years ago had had an accident, the nature of which was not clear, and who at intervals since then had suffered from hæmaturia. For this she was admitted into hospital four days previously. There was extreme weakness. In the right hypochondrium was a soft fluctuating tumour apparently connected with the kidney. In general the abdominal organs were normal, the urine was 1,200 ccm. in the twenty-four hours, clear, contained a little albumen, and had a specific gravity of 1.005 to 1.006, thus the symptoms resembled those of contracted kidney. There was moderate hypertrophy of the left ventricle. The following day there was headache, dulness of intellect, and then coma-uræmia. The probable diagnosis was hydro-nephrosis with contracted kidney, the cause of the uræmia closure of the ureter by kinking. Death took place in forty-eight hours. The autopsy revealed a peculiar condition: the liver was strewn with cysts of various sizes, and also the kidney, which was very much enlarged. There were also cysts in the ovaries, and hypertrophy of the left ventricle. The diagnosis of cystic kidney could not be certain. It was difficult because acquired cystic kidney was always double. Generally hydro-nephrosis was assumed. Puncture did not assist differential diagnosis, as the fluid was the same in both forms of disease; it contained a large percentage of urea. There were connective tissue bands between the cysts, as in contracted kidney. It was very peculiar that increase of urine should generally be found in such degenerated kidneys. No reason for this could be given. Recently Nauwerk had given a plausible explanation; there were actual tumours with a typical glandular growth in normal or already misformed kidneys. Children born with cystic kidneys died soon after birth. Acquired cystic kidney generally made its appearance in the fifth decennium. The patients died of chronic and subacute uræmia in consequence of renal insufficiency.

At the Free Society of Surgeons Hr. Hahn showed

TWO CASES OF RUPTURED LIVER.

The first, a young man, æt. 17, fell when cycling, lost consciousness, and on recovery he felt acute pain in the abdomen. There was great paleness and dulness over the depending part of the abdomen.

Laparotomy was performed at once; in the abdomen 2 litres of blood were found. On the convexity of the liver a rent 8 ctm. in length was felt, but at first not seen. Only on separating the suspension ligament could the liver be turned out so far that the rent could be

closed with fine catgut sutures. The abdomen was then closed, and recovery was uninterrupted.

The second case was one of gunshot wound. The point of entrance was between the middle line and the right margin of the ribs. The ball lay just behind and above the crest of the ilium, it could be easily felt and was removed without difficulty. Laparotomy was then performed. Entrance and exit openings were found in the liver, mesentery, pancreas, and parietal peritoneum. Pledgets of iodoform gauze were packed into each of the openings the ends being left outside. Recovery uninterrupted. In all cases of rupture of the liver the speaker advised operation as quickly as possible, in order to master the great danger—the hæmorrhage—and this was best accomplished by suture through the whole substance of the liver.

Hr. Israel remembered a case caused by a table-knife. The knife entered in the tenth intercostal space. The tenth and eleventh ribs were resected, the pleural cavity full of blood, the diaphragm being perforated. The abdomen was then opened, and the wound in the liver sutured and recovery took place.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, August 4th, 1899.

THE OPERATING GLOVE.

We are still reminded by Schloffer that the operating glove is an absolute necessity notwithstanding Doderlein's experiments and conclusions on the subject, and who is of opinion that a glove for operations in the abdominal cavity is useless as an aseptic agent if the surgeon use due diligence in disinfecting the hands, as no wound, whatever care may be used, can be kept quite free from germs. Schloffer has been experimenting with the leather gloves introduced for the use of surgeons by Wölfler, and now records some wonderful results. The glove, according to Schloffer's experiments, was first smeared over with a virulent culture, and then washed with a one per cent. Lysol solution, which again frees it from all danger of germ life; the glove is then put on the operator, the abdomen of a guinea pig is next opened and the hand maintained there for half an hour in a similar manner to the surgeon when removing morbid growths from the abdomen, with the result that out of sixteen animals acted on not one succumbed, while all the control animals conducted in the usual way died from sepsis.

The same results were obtained if a half per cent. solution of Lysol was used, or when the infected part was smeared over with vaseline.

From the foregoing, Schloffer concludes that the "Lederhandschuh" is a perfect protection against the transmission of germs into the peritoneum. He also adduces a large amount of clinical evidence to prove the benefits that have been derived from this provision in the operation of abdominal cases and deprecates Doderlein's efforts to diminish the importance of such a useful precaution. Lysol, according to his experience, is not injurious to the healing process and need not be dreaded. The leather glove is superior to the woven one.

GRANGRENE FOUROYANT.

Hitschmann, in his lecture at the Deutschen Gesell.

schaft, related the history of six cases of gangrene foudroyant, all in young people occurring after accidents. He thinks these cases must be quite separated from malignant œdema with which they have much in common. The severity of the injury, however, plays no part in modifying the course, or recovery, of the patient.

The characteristic symptoms of the disease are local objective coldness of the affected parts with subjective insensibility, while pressure produces a crackling noise under the skin. In addition to these the general constitutional indications of infection are present in the form of icterus and mental stupidity. The usual termination is death.

The local anatomical conditions observed during life can be demonstrated in the pathological room to depend on the constitutional influence. The internal organs have cloudy swelling and parenchymatous degeneration. There is no enlargement of the spleen, thus showing that the poison confines its ravages to the lymphatic paths in its progress, as bacteria are found to develop rapidly in the lymphatic vessels after death. The greatest number of these germs are to be found in the gas vesicles that crackle under the skin. The muscular tissue is broken down, and the colour quite lost, evidently from the effects of fermentation that takes place between the glycogen and albumen of the muscles.

In the six cases examined four were found to give in pure cultures a short stiff rod, which has the power of causing albuminous bodies to ferment with the evolution of butyric acid. In one of the cases this germ was found associated with another, to be frequently found in the soil and bowel, which is pathogenic in guinea pigs. Fraenkel has found an identical bacillus in a phlegmonous gasy inflammation.

In the sixth case the bacteria coli with a streptococcus were found. The bacterium coli produces fermentation in the carbohydrates alone, but do not in albumen, and is more likely to be present in the gasy phlegmonous formations met with in diabetes. But the Proteins produce another gaseous condition sometimes met with in pathological changes which were not found in any of the six cases. Whether the bacillus in the four preceding cases is an isolated and distinct species or a modification of Fraenkel's "gas-phlegmone" bacteria is yet difficult to affirm, but it is certainly one that decomposes muscular structure with the evolution of gas.

In such cases amputation of the morbid part is the only hope of saving life.

CONGENITAL DISLOCATION OF HIP JOINT.

Hoffa, in reviewing his success in this subject, said the mechanical treatment of congenital dislocations first practised at the hip joint was followed by a more heroic one, now known in history as the "bloody" operation for its correction; but recent surgery had supplanted both these operations by a more humane and satisfactory method, known as the bloodless operation, which had been recently popularised by Lorenz, while Paci, Schede, and Mikulicz had modified the operation. All the published facts were in favour of Lorenz's method of reposition in transposing the head of the bone forwards. Hoffa has operated on 84 unilateral dislocations and 73 bilateral. Lorenz's method was practised 64—42 unilateral and 22 bilateral. Kümmel is of opinion that extension is unnecessary, as reposition can be accomplished by

abduction alone. By Lorenz the leg is abducted, rotated outwards, bent and extended, as if moving the hand of a pump, by which means the capsule is stretched, the head ultimately springing into the cavity with an audible rush.

Lorenz further recommends a plaster of Paris support with the leg abducted and rotated inwards.

The treatment is useless when the child is over ten years of age. Out of 42 unilateral cases so treated only four were unsuccessful. The eldest was six.

Schede's method is extension pressure over the trochanter major. Thirteen were treated by this principle with good results.

Transposition in a large number of the cases is unavoidable from the thickened ligamentum teres filling up the acetabulum which allows the head to slip forward or upward, leaving on the whole a fairly good joint. On this account Lorenz's method of putting the joint in a plaster of Paris is good.

South Africa.

[FROM OUR OWN CORRESPONDENT.]

CAPE TOWN, July 2nd, 1899.

THE MEDICAL BOARD OF RHODESIA.

The profession in Rhodesia is very much up in arms against the Medical Bill of that colony. The principal objections appear to be that the Medical Board is to be entirely nominative, that it is to include a chemist and a dentist, and that the total strength may possibly not be more than three, thus putting the "auxiliaries" in a majority on purely medical questions. The Act, however, allows the board to have as many as nine members, and it is not likely that the Administrator will keep much below that number. Another objection is that Cape registration is to carry with it Rhodesian registration, but this is surely a very flimsy objection, as, except for the cases of a very few unqualified men registered retrospectively, at the passing of our Act, our requirements are stringent enough. It does not seem that our Rhodesian *confreres* have very good grounds for their agitation.

REGISTRATION FOR IMMIGRANT DOCTORS.

The Cape Medical Council has adopted a new regulation requiring a sworn declaration from applicants for registration to the effect that they have never been punished by any licensing body for any misdemeanour. This is to obviate the possibility of a man who had been struck off the *Register* in England getting registered here.

HYPNOTISM AMONG THE NATIVES.

The S. A. *Medical Journal* publishes an interesting paper by Mr. E. C. Long, of Maseru, Basutoland, on observations in hypnotising natives at the hospital at that place, of which he is medical officer. He reports having attempted hypnotism for the purpose of inducing anaesthesia, in seventy cases, succeeding completely in forty-five, and partially in six. When he failed, he had never made a second attempt. Sometimes the anaesthesia was complete, sometimes only partial, and in a good number even with complete anaesthesia, consciousness was retained. Generally the result was attained in from five to ten minutes, and in no case were ill-effects observed. The surgical cases included tooth extraction, opening

of abscesses, removal of carious bone, and exploration of hip-joint. Medically he used hypnotism in neuralgia, chorea, and hysteria. Considering that he was handicapped in the way of suggestion by having to use an interpreter, his results seemed fairly good, and he thinks that, to the single-handed South African practitioner, hypnotism is a very useful means of bringing about anaesthesia.

THE PREVENTION OF TUBERCULOSIS.

The Cape Town Branch of the British Medical Association discussed at its last meeting a committee's report on the prevention of tuberculosis. The matter was gone into somewhat exhaustively under a few headings, but nothing of special importance was elicited. At the next meeting the discussion will be continued, and it is probable that it will result in the establishment of an association on the plan of that in England, or possibly a branch thereof.

INFANTILE MORTALITY AND THE CRÈCHE.

Another Cape Town medical charity has been established, a crèche, very much wanted in this city. It has commenced under good auspices, and is likely to be of great benefit to the working classes. It is to be hoped that it may do something towards reducing the heavy infant mortality. During last month eighty-seven deaths were registered, and out of those fifty-six were under five years of age. Out of the total death-rate seventeen were credited to tuberculosis, a somewhat high ratio for a climate like this. Zymotic diseases account for twenty-five deaths. There is evidently room for preventive medicine in this good city.

The Operating Theatres.

THE SEAMEN'S HOSPITAL (DREADNOUGHT), GREENWICH.

PERIURETHRAL ABSCESS PROBABLY TRAUMATIC IN ORIGIN.—MR. WILLIAM TURNER operated on a man, set. about 35, who had been admitted complaining of pain and swelling in the scrotum. The patient stated that the penis when in a state of erection had been forcibly bent, with the result that the organ was still inclined to the left side; this accident had caused him great pain, and shortly after he noticed some swelling at the base of the penis. The accident occurred four days before the date of admission, and forty-eight hours after the accident he had a severe rigor, and felt very ill. He had not noticed any real difficulty in passing urine, though the stream was not so large as before, and there was a certain amount of pain during the act. He had never had any symptoms of stricture during his life, but some years before he had suffered from an attack of gonorrhœa. On admission he had a temperature of 102 degs., the tongue was dry and very furred. On examining the parts affected, the penis was found to be enlarged, swollen, and cedematous, and was inclined towards the left side; the scrotum was cedematous and between the two testicles, passing backwards, there was a tender, indurating swelling, undoubtedly corresponding to the peri-urethral tissue; this swelling extended forwards to within an inch of the glans penis, and backwards within about 2½ inches of the margin of the anus. Fluctuation could not be detected on account of the induration of all the parts. The

house surgeon had passed a full-sized instrument without difficulty into the bladder on account of the possibility of there being extravasation of urine. The diagnosis of peri-urethral abscess was made, and immediate operation was deemed necessary. An anæsthetic having been administered, and the patient placed in the lithotomy position, the parts having been shaved and purified in the usual way, an incision was made exactly in the *media raphe* of the scrotum, the testicles being held carefully apart on either side. The scrotum being thus divided, the inflammatory mass was exposed. On cutting into it about 3 ozs. of foul-smelling, putrid pus were evacuated and a large abscess cavity extending round the urethra and running up nearly to the glans penis was found; a pair of scissors were then introduced and the whole of the abscess cavity laid open forwards and backwards. The floor of this cavity round the urethra was found in a very sloughy condition, and on this account it was thought advisable to incise the bulbous portion of the urethra and pass a drainage tube into the bladder, in order to give the anterior part of the urethra a rest, it being very doubtful whether this could recover without the formation of a penile or scrotal urinary fistula. The parts were well washed with perchloride lotion and then packed with iodoform gauze, provision being made in the dressing for the soft catheter draining the bladder to be connected with an india-rubber tube passing into a vessel under the bed. Mr. Turner said that the cause of the patient's condition was doubtful, it was certainly not an ordinary lacunar abscess becoming peri-urethral occurring in acute gonorrhœa, as the patient certainly was not suffering from gonorrhœa. There was no communication with the urethra, and there was no urine in the abscess, thus excluding any idea of extravasation of urine. The most likely pathology of the condition was that a hæmatoma had formed from the injury, and that this had become infected in some way with micro-organisms, and probably the bacillus coli communis was the cause of the foul odour, it being a well-known fact that this organism is constantly found in abscesses in the region of the urethra and the rectum. There was no evidence as far as could be detected of any rupture of the corpus cavernosum on either side. Mr. Turner stated that in the treatment of cases of this kind he always advocated very free drainage and no direct treatment, such as scraping or the application of pure carbolic acid or chloride of zinc, as such treatment is liable to increase the sloughing of the surrounding parts. Had such procedure been adopted the floor of the urethra for a space of about 2½ inches would have been nearly certain to slough as the wall of the canal was already very thin and seemed almost a part of the sloughy base of the abscess.

A week after the operation the patient was going on very satisfactorily, the temperature came down to normal 24 hours after the operation and remained so. The bladder was still being drained by the perineum, the urine being normal; there were no sloughs in the wound at all, and the two sides of the cleft scrotum and of the wall of the abscess were covered with early granulations, all the sloughy condition had disappeared, and the wall of the urethra had not given way. The treatment that had been adopted was regular dressing with thorough irrigation of 1 in 2,000 perchloride lotion. On Mr. Turner's suggestion

the sides of the scrotum were brought together by the house surgeon, and a few stitches put in superficially to keep the opposing surface in apposition, whilst drainage was allowed for in an antero-posterior direction along the urethra. The next step in the treatment will be the discarding of the perineal drainage, together with regular catheterisation, so as to allow the perineal wound into the urethra to heal up and the drainage put along in the peri-urethral tissues gradually shortened, so as to permit of the complete filling up of the abscess cavity.

“SALUS POPULI SUPREMA LEX.”

WEDNESDAY, AUGUST 9, 1899.

THE ADDRESS IN MEDICINE AT PORTSMOUTH.

THE Presidential opening of the Section of Medicine at last week's Association meeting, delivered by Sir Douglas Powell, was a cautious, solid, and hopeful summary of recent advances in practice. His utterances were those of a cultured man who, ripe with past experiences, had not failed to gather to himself the facts and principles of modern progress. In this respect his utterances may be instructively compared with those of the chosen head of the contiguous Section of State Medicine. Both men touched upon serum therapeutics and upon bacteriology in relation to tuberculosis. But while the one appraised these researches at their proper value, and pointed out their possibilities and their limitations, the other indulged in a fierce onslaught upon the scope, the methods, the results, and even the ethics of bacteriologists in what he termed, with question-begging narrowness, “the insane hunt after the tubercle bacillus.” Whatever grain of truth this reactionary attitude may contain yet it must be abundantly clear to all reasonable men that the chair of an

important section of a great assemblage of representative medicine in Great Britain was not a fit place from which to issue rhetorical thunder of that kind. Comment upon a Presidential Address is forbidden, or, we venture to say that, at the meeting a strong protest and entire logical refutation would have been at once brought forward. If insanity be inseparable from the quest after the acknowledged source of the dread pestilence of tubercle, then in Heaven's name let a fair proportion of our best and brightest intellects sacrifice themselves for the love of mankind and go mad forthwith. It is a relief to turn to the broader views of Sir Douglas Powell, who opened his remarks upon bacteriology by saying that the science “in its application to diagnosis and treatment in practical medicine is yet in its infancy; but it is a very robust infancy, full of promise, the complete fulfilment of which none of us will live to see.” He pointed out that bacteriological work must necessarily be a matter of expert investigation, as it would be impossible for the busy practitioner to find the time and the necessary appliances for the purpose. At the same time, it may be remarked that an elementary examination, with the aid of cover-glasses and a few easy cultures, is becoming of increasing importance. At the same time, there can be no doubt as to the truth of the main proposition that practitioners of medicine will in future have for the most part to deal with the results of bacteriology, both in abstract scientific research and in practical bedside work. As to serum therapeutics, the speaker recognised the immense value of the knowledge that every infection required a separately prepared serum for its treatment. Some of our failures might be explained by the fact that a manifold pathogenic pathology lay at the root of many diseased conditions. Such associated poisons might be recognised in the third, and often in the first stage of enteric fever, in the suppurative stages of scarlatina, and perhaps in gonorrhoeal rheumatism. But while the neutralising the specific poison of various diseases by appropriate remedial serums would relieve the practitioner of vast anxiety, yet, on the other hand, his responsibility would be greatly increased by the absolute necessity of early diagnosis, and by the scrupulous care needed to prevent the introduction into the body of his patient of further dangers of microbial origin. As regards phthisis, while advocating the use of every ordinary measure of precaution in the way of cleanliness, avoidance of dust, and disinfection of sputa, Sir Douglas Powell, on the other hand, counselled the careful eschewing of exaggerated statements likely to alarm the public as to the contagiousness of the disease. One striking point to which he drew attention was the enormous prevalence of bovine tuberculosis not only among stall-fed cattle, but also in those kept under good open-air conditions. He argued that, like malaria, tuberculosis will probably be found to have a double origin from purely microphytic as well as from parasitic infection. He

remarked that we may hope by rigid sanitary control to reduce considerably the present death rate of 14 per 1,000 living due to consumption, a figure which already marked a reduction of 20 per 1,000 living from the same cause. In his belief there exists a mephytic laboratory beyond our special control, yielding organisms ever ready to attack the unwary and those whose vitality is depressed. General sanitation and cleanliness are our first line of defence. Wherever the conditions of insanitation, dampness, deficient sunlight, and the prevalence of favouring diseases are present there aggressive activity may be again looked for.

DISCUSSION AT GENERAL MEETING OF THE ASSOCIATION.

THIS meeting had been looked forward to with special interest by members, from the fact that a number of notices of motion had been lodged. At least half of these propositions had been ruled out of order by the late President of Council, Dr. Saundby. Under these circumstances it is much to be regretted that the somewhat arbitrary position taken up by Dr. Saundby, on behalf of the Council, had to be sustained in his absence. Dr. Ward Cousins read a letter of apology for absence from Dr. Saundby, who said that he "had to return to Birmingham to give evidence at the Assizes, or he would not have run away from" that discussion. Now, the general meeting took place on Wednesday, August 2nd, from 2 to 5 o'clock, in the afternoon, and Dr. Saundby was present at functions of the Association, both in the afternoon and evening of that day, and was also seen in Portsmouth next morning. With these facts in view it seems abundantly clear that members of the British Medical Association are entitled to demand a further explanation from one who continues to occupy a high position on the Council. Dr. Lorrimer Hart struck the keynote of the position of members in the debate by rising on a point of order to ask under what powers the President of Council (Dr. Saundby) had ruled out of order certain notices of motion duly sent in for discussion at general meeting. The originally excluded motion alluded to by Dr. Hart was raised nominally, and to put himself in order, on a reduction of the editor's salary by £10, in order to call attention to the exclusion from the journal of several matters of prime importance to the profession. That was ruled out of order, and so did not come before the meeting. In the course of the discussion, however, the whole question of the powers of members in general meeting over the expenditure of the Association upon its journal was raised, and practically a vote of censure was passed upon the Council. The specific resolution concerned was proposed by Mr. Victor Horsley, seconded by Mr. Tomlin, and carried. It ran as follows:—"That inasmuch as the President of the Council, and subsequently the Council itself, have ruled that the members of the Association have no right to discuss in general meeting the

question of the expenditure of the Association upon its journal, this meeting strongly disapproves of the action of the Council." In the upshot Dr. Hart moved a modification of his original excluded motion, which was accepted by the president (Dr. Ward Cousins). It ran:—"That the attention of the Council be invited to the exclusion of the editor of the *British Medical Journal* of matters of interest to the Association and to the profession; especially in reference to the memorials of the General Medical Council against the certification of unqualified persons by registered practitioners; and to his silence on such matters obstructing reform." This resolution was seconded by Dr. Frederick Spicer and passed. Curiously enough, the issue of the *British Medical Journal* that has since appeared (August 5th), emphasizes the position by omitting from what would have been otherwise a fair report all mention of two most vital subjects that took a conspicuous place in the discussion. Those two omissions were:—I. The mention of petition of fellows and members of the English College of Surgeons claiming the privilege of electing their representative on the General Medical Council. II. Mention of the memorial addressed to the General Medical Council against the certification of unqualified persons by registered practitioners, and signed by over a thousand medical men. It should be added that the meeting absolved the editor from personal responsibility.

A SERIOUS INDICTMENT AGAINST THE NAVY AND ARMY MEDICAL SERVICES.

IT was, perhaps, quite in accord with the natural fitness of things that Professor Ogston, of Aberdeen should have discussed in his address in surgery at the annual meeting of the British Medical Association the affairs of the Navy and Army Medical Services. In the midst of such a naval and military community he would be certain to attract not only an attentive but an appreciative audience. Our *confidères* in the Services, however, were probably not quite prepared for the outspokenness in which Professor Ogston indulged. The picture which he presented of the unpreparedness and inefficiency of the two medical departments must have been a revelation to many to whom the facts in this regard were unknown. But such an address was nevertheless well-timed and apposite. It has for long been known, for example, that the officers of what is now the Royal Army Medical Corps have felt extreme dissatisfaction with the want of sympathy displayed by the War Office towards their efforts made to increase the efficiency of the military medical service. No one knows better than the army medical officer how deficient his department is in the matter of modern medical equipments. Instead of doing everything in their power to foster the zeal for efficiency among their medical officers the War Office seem to make a point of deliberately following the opposite policy. The following quotation from Professor Ogston's address will reveal something of the state of affairs in this regard. "Under the existing system no junior officer

of the Royal Army Medical Corps has any opportunity of practising modern surgery; even if an occasion offers he is tied down by modern restrictions and impediments enforced by his seniors, and his natural desire to prepare himself for the highest work is disregarded and repressed, so that few, if any, are capable of the class of surgical work which will be expected of them by the country, and for the non-performance of which they will be unjustly blamed when the test of war is imposed upon their performances. So long as the medical services afford their surgeons no proper facilities for acquiring and maintaining a competent knowledge of their highly important and necessary matters; so long as the junior medical officers, as the junior medical officers, have neither the chance nor the encouragement to perfect themselves in their science, and especially in what would lie before them in the event of a war, it can hardly be wondered at that a service entailing on those who enter it what is from a professional point of view almost an intellectual sterility, should be a mode of life our best graduates recoil from and which few of them can be persuaded to adopt." The natural corollary from this is, that the services must either adapt themselves to the altered spirit of the times, or remain undermanned, and lacking in everything which an up-to-date department should possess. It seems a curious anachronism that the poorest subjects of Her Majesty should have an opportunity in our hospitals of profiting by the benefits of modern medicine and surgery, when these are practically denied by the War Office and the Admiralty to the soldier and sailor as long as he remains in the service. That is really the position of affairs, and there is no disputing the fact. Under the present system under which the medical departments are being conducted, it would be impossible to predict the consequences in the event of this country becoming involved in a great war. We do not for a moment deny that in our expeditions in the Soudan and to the North-West Frontier the medical department was found efficient, and worthily earned the praise bestowed upon it. But the authorities have been repeatedly reminded that the past little wars in which we have been engaged cannot be regarded as affording any test of the requirements of the department. On the other hand, were we to be engaged on equal terms with a large European power, the belief among those best qualified to judge is that the horrors which occurred during the Crimean War would be repeated. But however melancholy it may be to discuss these matters in respect to the Army Medical Service, it is more so still to contemplate the picture drawn by Professor Ogston of the horrors in store for the wounded on board our battleships during a naval engagement. Its central feature is that everything on board ship that can destroy life is in the highest perfection, while everything that can save it is of the rudest description and behind the age. Professor Ogston states that on board none of Her Majesty's vessels is there any possibility of performing a laparotomy for a gunshot wound of the abdomen. There is neither

accommodation, nor instruments, nor accessories for the purpose. We have not space to discuss the many excellent points put forward with the object of remedying the defects to which attention is drawn in the address. Suffice it, however, to say that Professor Ogston makes many valuable suggestions which the authorities would do well to take into their serious consideration. We believe that the address is bound to bear good fruit, inasmuch as even if the authorities remain obdurate, the grave indictment to which it amounts cannot fail to excite earnest attention among the medical and lay public.

Notes on Current Topics.

A Retrograde Sanitarian.

Food for unpleasant reflection is afforded in the remarks with which Dr. Wilson opened the Section of State Medicine at the annual meeting of the British Medical Association. We are sorry to have to admit that the sum and substance of this address was the belittling of the work of bacteriologists especially apparently because of its association with experiments upon animals. With considerable temerity, and quite inconsequentially, Dr. Wilson avows that he is prepared to contend that the indiscriminate maiming and slaughter of animal life with which bacteriological methods of research and experimentation are, in his opinion, inseparably associated, cannot be proved to have saved one single human life, or lessened in any appreciable degree the load of human suffering. Dr. Wilson, of course, is entitled to hold any opinion that he likes upon the subject, but it is a pity that in his official position as president of the section of State medicine he should have reiterated statements entirely opposed to the teaching of modern scientific research. To hold such retrograde views upon the subject of bacteriology, for example a science still in its infancy, and, we may reasonably believe, full of promise in the near future, and to express such views officially, is not only calculated to do harm to the profession, but also to disturb the confidence of the public in the validity of medical progress. What sensible person can admit, because bacteriologists have so far failed in their attempts to isolate and cultivate a specific organism of scarlatina, whooping-cough or measles, as urged by Dr. Wilson, that no such specific organisms exist. To accept a statement of this nature is to imply that finality has been reached in the methods of bacteriological technique, but who can imagine for a moment that this is the case? Bacteriologists are gradually feeling their way, in an entirely new field of science, and time and opportunity must be permitted them to work out the problems with which they are confronted. In the legitimate prosecution of their investigations experimentation upon animal life is indispensable, and is at the same time permitted by law, and it was, therefore, scarcely the duty of a medical man, placed by his *confreres* in a

position of trust and responsibility, as Dr. Wilson was, to avail himself of the opportunity to throw discredit upon the work of some of the ablest medical scientists of the day, whose claims to honesty and singleness of purpose moreover are fully equal to those advanced by the orator on his own behalf.

The Section of Tropical Diseases.

THANKS to the enthusiasm which has been thrown into the problem of promoting the study of tropical diseases this subject has forthwith attained to the dignity of a separate section. In the introductory remarks with which Dr. Thin inaugurated the section at Portsmouth we get a glimpse of the immense amount of patient study and observation which have been devoted to the study of malarial fever. Day is apparently just beginning to dawn in this dark region of medicine, but at the price of many deceptions and disappointments, due in part, no doubt, to the desire to discover some one fact which should explain and co-ordinate the protean manifestations of the diseases classified *en bloc* as malarial. Hitherto all classifications have been made on a purely clinical basis for the simple reason that no trustworthy pathological data have been available for a more scientific arrangement. To the general reader papers dealing with the results of recent investigations on this subject are more or less unintelligible, owing to the large number of new terms which grace the terminology of this particular department of research. We are fain to await the services of an interpreter who shall give us a plain statement of facts divested of the technical obscurities which at present close the avenues of knowledge to all save experts. The evidence in favour of the mosquito being the means of transmitting, at any rate, certain forms of malaria seems tolerably conclusive, though as malaria occurs in parts of the world where mosquitoes are unknown this insect cannot well be the only, possibly not even the principal, means of its transmission. We are glad to see that due credit is given to Italian observers for the many years of patient unrecompensed labour which they have devoted to the subject. If they did not earlier achieve results of a kind to command general assent, this fact must be attributed to the inherent difficulties of the subject. It is hardly possible to exaggerate the importance of this branch of investigation, bearing as it does upon a group of diseases which virtually close large sections of the globe to the white man.

Matron and Doctor.

THE Chelsea Board of Guardians have been much occupied of late concerning a dispute which has arisen between one of the surgeons to the Infirmary and the matron. We gather that a man had been operated upon for hernia and was left with instructions that he was not to be moved without permission in view of the danger of reopening the wound. In the face of those instructions the matron, in order to guard against bedsores, ordered a pillow to be placed

under the loins, with the result that the wound reopened and dangerous hæmorrhage supervened. As the matron declined to acknowledge having committed an error of judgment, for that is all it amounts to, the matter was brought before the Guardians with a request that the facts should be laid before the Local Government Board. This, however, they were indisposed to do, and after a brief discussion, the motion to that effect was negatived. The members, or some of them, who voted in the minority asked permission to see the documents, but as the clerk suspected that this was for the purpose of obtaining information to be sent direct to the Local Government Board, he took upon himself to refuse access thereto in spite of a favourable opinion by the chairman. He held, like the President of the General Medical Council, that the Board as a whole could alone order him to produce the documents in question. The matter in dispute may appear a small one but it must not be forgotten that a very important principle is at stake—viz., the subordination of the nursing, to the medical, staff. Obviously if nurses and matrons take upon themselves to disobey the orders of the Medical Officer, with the approval of the Guardians, the Medical Officer must disclaim any responsibility for the results to the patient. Of course one would like to see surgeons and nurses working together harmoniously in the interest of their patients, but this cannot be unless discipline is maintained. The matron after all was guilty merely of injudicious interference, but her fault is aggravated by her subsequent attitude, and if she persists in that attitude the Local Government Board, in default of the Guardians, will, sooner or later, have to adjudicate.

Cockles and Typhoid.

A SERIOUS epidemic of typhoid has prevailed in Chichester for some months past. Fifty-five cases have occurred, and close enquiry revealed the fact that in at least 20 of these the patient had partaken of local cockles. These come—as all larger fat cockles do—from the black mud in the neighbouring harbours which was abundantly watered with sewage from the neighbouring villages. In one instance the father of the family, the only one of eight who abstained from the cockles, was the only one who escaped the typhoid.

Recent Vaccination Returns.

IN spite of the fuss that have been made about the large number of conscientious objectors, we have it on the authority of the President of the Local Government Board that the total number of certificates of successful primary vaccination received by the vaccination officers during the first six months of the present year amounted to 353,992 as against 277,821 in the first six months of 1898, that is to say there has been an increase of upwards of 76,000 primary vaccinations, equal to more than 27 per cent. in the first six months of the present year as compared with the corresponding period of 1898. Mr.

Chaplin added that these results had been obtained in the first six months of the Act notwithstanding the difficulty of giving effect to an entire change of method throughout the country from stationary to domiciliary vaccination, and also in spite of the fact that in numerous cases there was very considerable delay in the fixing of fees and the appointment of officers, and that in some cases, such as Leicester for instance, the necessary appointments are not made even yet.

The Food Preservative Danger.

FOR some time past the dangers of the use of antiseptics in the preservation of food has been increasingly apparent. Boric acid, salicylic acid and many other chemicals of a more or less potent nature, have been discovered in food stuffs of various kinds, and have in several instances formed the subject of prosecutions. It can hardly be said, however, that the judicial attitude with regard to this form of adulteration, for so it must technically be termed, has been yet clearly and authoritatively defined. The scientific knowledge of the agency of bacteria in putrefaction is of recent growth, and the subsequent practical application of the newly born science have, in many instances, introduced into the ethical life of the community problems that still await a satisfactory solution. So far as the addition of chemical preservatives is concerned the greatest offenders have hitherto been the milk and the butter man. As a general rule the drug chosen for their purpose is comparatively harmless, but a report comes from New York of the use of a deadly poison, to wit, nothing more nor less than arsenic. The fact was brought to light by the poisoning, in Brooklyn, of nine persons, two of whom are not expected to live. The occurrence was traced to milk, an analysis of which revealed the presence of arsenic. As the outcome of further investigation the dairyman confessed that he used the poison systematically in order to keep the milk sweet. Medical men generally will do well to bear in mind the fact that some cases of obscure illness may be due to food preservatives. If the milkman is going to embark in a wholesale round of chemical experimentation, the community will find a fresh terror added to their daily life.

Gunshot Wounds in Civil Life.

THE increasing use of the revolver among a certain class of the community has more than once been pointed out by police magistrates, and confirmatory evidence of the fact was given last week by Mr. Butlin in his opening address in the Surgical Section at the British Medical Association. In his experience of late years the use of firearms, for the most part the revolver or pistol, in civil life has increased alarmingly. "If" he said, "a young man has a grudge against his fellow workman he buys a pistol and shoots him; if a youth quarrels with a maiden he shoots her, sometimes fatally, then turns the weapon against himself, but rarely with such success that he

blows out the little brains that he has." The records of St. Bartholomew's Hospital show that while in the seventies and early eighties the average number of gunshot wounds used to be about three a year, the average lately has been at least twelve for the same period. Of course the moral of this state of things is that an Act should be introduced either restricting the sale of such weapons as pistols and revolvers or of providing that they shall not fall into the hands of those likely to improperly use them. However, any effective legislation, in this direction might be a difficult matter to accomplish, but it goes without saying that unless something is done to put a stop to the facilities for causing gunshot injuries in civil life the time will come when every peaceful citizen will be compelled to carry a "six shooter" in self defence.

A Medical Slander Case.

WE congratulate Mr. Hugh Cameron Kidd, the Medical Officer of Health for Bromsgrove, in charge of the local isolation hospital, on the issue of his action for damages against a slanderer. The defendant was a baker who, possibly with the best intentions, made, published, and reiterated a series of grave charges against Mr. Kidd in connection with the management of the institution. The hospital in question is apparently a temporary structure, mainly consisting of tents, hence many of the amenities of properly-constructed buildings were lacking. The fault, if any, for these shortcomings obviously could not be placed at the door of the medical officer, who is only concerned with the medical care of the inmates. The hypercritical baker, however, charged him with neglect and gross mismanagement, and at the trial he waived the question of privilege and attempted justification, thereby exaggerating the recklessness which originally led him to formulate the allegations. Mr. Kidd challenged the allegator, and the jury, after a two days' trial, gave a verdict in favour of the plaintiff for £150 with costs, coupled with an intimation that, but for the social position of the defendant, they would have awarded a much larger sum. We would not for a moment seek to curtail the right of free criticism; indeed, the possibility of this is one of the best safeguards we can have for the good management of public institutions. It is, however, one thing to criticise an institution and another to attack the reputation of a particular officer, and the latter course can only be condoned when the hostile critic fully authenticates his assertions in a court of law. British juries can generally be trusted to do justice in such matters, and the result in this instance confirms the opinion we had formed.

The Malaise of "Paddling."

PADDLING in moderation is not attended with harm, but carried to an extreme it is likely to cause symptoms of malaise indisputably harmful to children. The physiological effect of the pastime is to cause distention of the cerebral blood vessels, the action of the cold water upon the leg,

being to drive the blood away from the lower extremities. Probably most of the organs in consequence of this also become unduly vascular for the time being, but it is chiefly in the brain that the symptoms are manifested. Headache is the most common symptom of prolonged paddling, and irritability and lassitude are also noticed in the children, the cause of which is often overlooked. Parents and others having charge of children at the seaside should therefore be careful to bear these facts in mind, and imit the "paddling" zeal of their charges to a short period during the day.

A Curious Poisoning Case.

MR. WILKES, practising at Sparkhill, near Birmingham, was called in last week to a girl who exhibited symptoms of what he took to be hysteria, but which subsequently proved to be due to the effects of "vermin poison" (strychnine), to which she ultimately succumbed. Naturally enough public opinion is very hard on the practitioner who failed to make the diagnosis in time to save the girl's life, but we, on the contrary, are disposed to sympathise with him. The public cannot possibly appreciate the immense and even insuperable difficulty which must attend a correct diagnosis in the absence of any suggestion of attempted suicide. The mild spasms which usher in the more formidable toxic manifestations of strychnine, for example, point to nothing in particular, and one is compelled to await more precise information, either clinical or verbal, before deciding as to the nature of the affection. When a case is labelled "attempted suicide," treatment is vastly simplified, but in some instances this nature can only be a matter of inference, and inference means time for observation and reflection. This may seem unsatisfactory to the public, but it must be so.

Urine Analysis by Chemists.

THE organs of the pharmaceutical press have been discussing the propriety of chemists taking up the analysis of urine for medical men, and, with certain reservations, the idea has much to commend it. If chemists care to undertake this particular branch of research, however, they must qualify for the work, and, so far, their training is hardly such as to fit them for the task. Medical men are not likely to have recourse to their services in this direction merely in order to ascertain qualitatively the presence of albumen or sugar in the urine. This much is well within the time at the disposal of the busiest man. What would be required is the exact quantitative analysis not only in respect of albumen and sugar, but in regard to urea, uric acid and the various abnormal constituents of morbid urine. To be able to furnish trustworthy reports on these lines would require very special training and experience of a kind not at present within the reach of most retail chemists. When our universities awaken to the opportuneness of instituting a degree in pharmacy, urine testing and the analysis of alimentary substances might well form

a conspicuous item of the curriculum. By the time a chemist reached this stage of graduation, however, he would probably relinquish counter-prescribing and the sale of tooth brushes and soaps in favour of the more purely scientific departments of his calling, and it is probable that his fees would be on a scale which would indispose the average practitioner from having recourse to his assistance. Abroad it is usually the *pharmacien* who is entrusted with the analysis of urine, for the simple reason that for their proper execution the process takes more time and requires more technical appliances than are at the disposal of the average practitioner. For the present the retail chemist in this country is neither willing nor able to undertake such work, and it is doing him a sorry service to publish for his benefit little books which cannot reasonably be expected to do more than give him a smattering of the knowledge required for this department of research. At some time in the future it may well be that the medical practitioner, who by that time will have given up dispensing his own medicines, will get his analyses and bacteriological examinations done by his chemist, but this time is not yet.

A Spectacle Fellow.

THE only person, as far as we recollect, who addressed a lady as a "fellow" was Dick Swiveller, who applied that term of endearment to Miss Sally Brass, but the Spectacle Vendors' Society has extended the title to a Miss Frances Troulan, who is the premier female member of that very venerable society. At an outing which it had on the 28th, the lady was present, and held the place accorded by chivalry at a subsequent dinner, at which she was presented with a bouquet, had her health proposed, and made a speech. We offer our congratulations to Fellow Troulan.

The London Universities Future Habitat.

A TREASURY minute was issued last week which declares the terms upon which the University is to occupy part of the buildings of the Imperial Institute. The "consideration" is the payment off of a mortgage of £40,000, and a number of debts to the amount of £15,000, and for these sums the University is to acquire the eastern and central parts of the building and certain other accommodation within its walls.

The Progress of Cremation.

ALTHOUGH cremation has not yet attained to the dignity of a craze it is making steady progress, witness the fact that from three cremations in 1885 the annual number had risen in 1898 to 240. This method of disposing of one's remains only appeals to the "intellectuals," or, at any rate, to persons of such social rank as ensures a cultivated mind. One reason *inter alia* for its lack of popularity among persons of a lower social and intellectual status is that the matter must be thought over and decided upon beforehand, and the average person respectfully insists on limiting his field of vision to the near

future, and nothing is less to his taste than discussions bearing on the disposal of his mortal remains.

The Annual Museum.

THE ever-increasing sums charged for space at the annual museum, which is one of the features of the meetings of the British Medical Association, and the scant consideration shown for the comfort and accommodation of exhibitors, who have gone to the expense of putting up and furnishing stalls, appear to have had the inevitable effect of alienating a large number of those who, in years gone by, gladly availed themselves of this opportunity of bringing their wares before the profession. The building at Portsmouth where the museum was located was a modern reproduction of the famous Black Hole of Calcutta. Unprotected from the solar rays, which were tropical in their incidence, the temperature oscillated about 80 degs. F., and, as there was a complete absence of ventilation, the exhibitors and their rare victims gave unequivocal signs of cerebral irritation. We trust that at future meetings more consideration will be meted out to a very deserving class of men. The fact that commercial instincts underlie their propaganda does not detract from the intrinsic usefulness of these annual exhibits. The country practitioner is thereby enabled to examine the year's innovations and novelties, his practical knowledge in matters pharmaceutical and instrumental is brought up to date, and unquestionably his visit to the annual museum is by no means the least useful item on his programme of engagements.

The Value of a Hand.

A CASE of some interest from an insurance point of view was heard last week at the City of London Court. A labourer lost his right hand in consequence of a heavy barrel falling upon it, and he sued his employers for damages. Under the Employers' Liability Act the case was given against him, but under the Workman's Compensation Act the decision was given in his favour, and his employers have been called upon to provide him with nine shillings a week for life. The case undeniably shows how well provided for the workman is now in the event of accidents occurring to him during his employ. A few years ago the law could not have helped such a man to obtain any compensation in a case of this kind.

Measles in Dublin.

THE epidemic of measles from which Dublin has been suffering, and which appeared to be decreasing, has now again increased—75 deaths from the disease took place in the week ending July 29th, being more than double the number (35) in the previous week.

PERSONAL.

DR. J. R. THORNTON, of Bournemouth, has been appointed President of Council of the British Medical Association vice Dr. Saunby.

THE Baly medal has been awarded by the Royal College of Physicians of London to Professor Sherrington for his researches on the physiology of the nervous system.

DR. E. STARLING, F.R.S., has been elected to the Jodrell Professorship of Physiology by the council of University College, London, in succession to Professor E. A. Schäfer.

THE Queen has conferred the decoration of the Royal Red Cross upon Miss Annie Gill Mark, superintendent Army Nursing Service, and Miss Gertrude Mary Payne, Army Nursing Service, in recognition of their services in tending the sick and wounded.

THE Bisset Hawkins Gold Medal has been awarded to Dr. James Burn Russell, M.D., LL.D. Glasgow, Medical Adviser of the Local Government Board for Scotland, by the Royal College of Physicians of London. This is the first award which has been made of the medal, which was founded in 1896 in memory of the late Dr. Francis Bisset Hawkins, to be given triennially for work done in advancing sanitary science as in the opinion of the college deserves special recognition.

Correspondence.

We do not hold ourselves responsible for the opinions of our correspondents.

OUR RULERS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR.—Why does "R. B. W." not write over his name? Why is our profession such a cowardly gang? We are ground to powder by our rulers, and yet we have not a kick in us. They fleece us in their schools and hospitals and colleges and universities, and then cut the ground from under our feet by turning hospitals that were intended for the poor into so many hotels for the rich. Alone among all professions, the medical man of to-day cannot offer the meanest privilege to his son in going to the father's profession. The General Medical Council established (bless the mark) an apprenticeship system, driven by the reports of their own visitors as to the insufficiency of the present system, and by conscientious men among themselves, but they so contrived it as to make the whole scheme unworkable, and so it has completely fallen through—a brilliant example of how not to do it. Look at what our Dublin rulers have done. The Dublin licensing bodies established some time ago a precious regulation under which a knowledge of pharmacy is to be acquired—where do your readers think? Well, in the lecture-room, of all places in the world. Some time since I presented a memorial to the General Medical Council on the subject of a notorious and admitted fraud on the curriculum of the General Medical Council in the existence of side doors through which parties may slip who would not face the public examinations, on the collapse of the apprenticeship regulations, and on the interference with the statutory rights of members. What do you think they did? They strangled it. Afraid to publish and unwilling to deal with it, they allowed it to die out in the hands of the executive committee. I now publicly call on the elected representatives of the professional masses to show a little more loyalty and a little more energy than they have done, and bring the whole matter forward at the next meeting of the Council. Why should these gentlemen show any loyalty or any energy? Are they not all, or nearly all, members of the governing classes themselves? I am ashamed of the profession I belong to, for when, in Ireland, at all events, we might have re-

turned men who would confound our blunderers, we, like the Roman plebs of old, went basely and meanly into the enemies' camp for our tribunes, and we certainly have no right to complain of the result. I shall appeal to the Privy Council, and shall in that way ensure publicity for my memorial, and compel our worthy representatives to show their hands.

I am, Sir, yours truly,
THOMAS LAFFAN.

Cashel, Ireland, August 1st, 1899.

THE INSTITUT VERNEUIL.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—My attention has been drawn to a very able article upon La Baule Hydropathic Establishments appearing in your issue of the 2nd inst.

I notice two errors, which however in no way detract from the value of the article from a medical point of view.

I represent the proprietors of the establishment in England, and all inquiries by intending English visitors should be made of me, and not as stated in the article. The management thought this the better plan, as, being near at hand, I am enabled to spare intending English visitors trouble and to avoid delay.

The terms for children I may add are £10 to £12 a month inclusive of medical attendance, baths, &c.

I shall be obliged if you will kindly insert this letter in the next issue of your valuable paper.

I am, Sir, yours truly,
RALPH S. LEACH.

10 Serjeant's Inn, E.C.
August 3rd, 1899.

MR. VICTOR HORSLEY ON THE WORK OF THE GENERAL MEDICAL COUNCIL.

WE have received from Mr. Victor Horsley a copy of his sixth annual report to the registered practitioners of England and Wales, the salient portions whereof are as follows:—

Mr. Horsley recapitulates the incidents of the struggle between himself and the president of the General Medical Council respecting the right of members to have access to documents—a struggle which terminated virtually in favour of Mr. Horsley.

The result is that the unconstitutional action which he protested against has been entirely abrogated and the rights of the members of the Council are now, after twelve months of futile and expensive delay, fully restored to them. He concludes with the hope that we shall not have any more absurd attempts to introduce a despotic régime which “is entirely out of date in the affairs of this or any other public institution.”

In reference to the Hunter case, Mr. Horsley remarks that in the session just concluded he at last, against an unscrupulous resistance, headed by Mr. Carter, gained an opportunity to draw attention to the scandalous procedure of the officials of the Council in relation to the Hunter case. Mr. Horsley comments, in what appears to us to be unnecessarily violent terms, upon the action of the law officers and of the Penal Cases Committee in the matter. He points out that the original charge of the illegal use of an American M.D. was, without the authority of the Council, converted into one of the illegal use of the titles physician and surgeon, and he challenges the right of the Penal Cases Committee to resist the appeal without the sanction of the Council.

Passing on to the conduct of the legal business of the council, Mr. Horsley points out that no formal appointments have ever been made constituting any person or persons “legal assessor to the council,” so that it is obvious the council is at liberty to employ any legal assistance it may prefer.

In respect of personation and fraudulent misrepresentation of the register, Mr. Horsley recalls that the special committee of which he was appointed chairman duly reported, but when the report was presented the council recognised that the subject was an extremely complex and

important one, and it was therefore agreed that the determination of the alterations which the committee suggested ought to be made in the procedure of registration and in the work of the office, should be postponed till the November Session of the present year.

In discussing the present state of the reciprocity question, Mr. Horsley observes that the reciprocity question has come up in a totally different and more pertinent form, viz., on a species of international bargain which was proposed by the Italian Ambassador, and concerning which the executive committee had already illegally taken it on themselves to make a statement to the President of the Privy Council. In that statement the executive committee had expressed a desire to see the privileges and rights of medical practitioners in this country extended to all foreigners who could offer in exchange the privileges of practice in their own country. The adoption of the executive committee's principle would, of course, render entirely nugatory the whole system of medical education and registration in the United Kingdom. The matter was ultimately postponed to the next session.

On the examination for higher qualifications, Mr. Horsley relates his several attempts to induce the Council to take cognisance of the defective nature of the examinations for the fellowship of the Faculty of Physicians and Surgeons of Glasgow. His first attempt was thwarted by the President, to whom the memorial had by error been addressed (instead of to the Council), and his second attempt, on an impersonal and purely legal basis, failed by reason of a number of members of the Council abstaining from voting. In this particular the division list on page 72 of the minutes of the Council (Vol. XXXVI.) is interesting because it shows that abstention from voting was resorted to in order that the view expressed by the officials of the Council should be protected regardless of the facts of the case.

Mr. Horsley then deals with illegal certificates of proficiency in medicine, surgery, or midwifery. This important matter, he remarks, prejudiced as it was by the language and terms of the memorials presented to the Council from the Corporate and Medical Reform Association, was treated very unsatisfactorily by the Council. The executive committee had had the matter referred to them, and had, of course, reported to the effect that nothing ought to be done. Thereupon Mr. Brown and he moved that a special committee be appointed to report on the subject at the next session, but the amendment was lost.

MEDICAL AID ASSOCIATIONS.

With regard to the serious matter of Medical Aid Associations the committee appointed, under the chairmanship of Dr. Glover, to report to the Council on that subject at last presented their long looked for report. Practically, that report dealt with only two points. First, it proposed the appointment of a Conciliation Board; and, secondly, the adoption of a resolution of general disapproval of medical practitioners taking office under Medical Aid Societies. As he was unable to obtain any satisfactory explanation from the members of the committee respecting the formation of the Conciliation Board, or the conditions under which the profession was asked to join such a board, he spoke against the proposal as being an inchoate one, and also because the report of a conference held between Dr. Glover's committee and certain representatives of the Friendly Societies showed beyond all manner of doubt that the so-called Conciliation Board would not be allowed to take into consideration the important point of wage limit. In fact, the attitude of the Friendly Societies on the subject of wage limit is actively hostile to the opinion of the medical profession. Under these circumstances, unless the conditions under which such a Board is to meet are clearly laid down, he could not see how its deliberations could be of any service, nor how the profession is to elect its delegates, nor how the Board is to enforce its decisions, nor how the expenses of the business are to be met. During the discussion in the Council very serious statements were made by Mr. Bryant and Dr. Glover, which evidently influenced many members of the Council in favour of the Conciliation Board, but for which no

specific authority was forthcoming. He therefore advises the profession to reserve judgment until it has distinctly before it in print all the necessary conditions for the establishment of such a Board.

Mr. Horsley congratulates the profession on the warning addressed to persons accepting office under Medical Aid Societies, and upon the progress made at the recent Session in regard to the legislation further inhibiting unqualified practice by persons forming themselves into companies.

Regarding the Midwives Bill, Mr. Horsley points out that the Bill will doubtless come up next Session when care must be taken to prevent its passage in its present pernicious form, since it neither secures safety to the public nor adequate observance of the interests of the profession.

Mr. Horsley congratulates himself on the fact that he was enabled to secure the registration of the F.R.C.S.I. on the Colonial List as an additional qualification, in spite of the uninformed opposition of the law officers of the Council.

In respect of the scientific education of students, Mr. Horsley comments in strong terms on the unfortunate fact that the English Conjoint Board, *i.e.*, the College of Surgeons and the College of Physicians, had adopted an attitude of hostility to the provisions of the Council for securing a thorough scientific training to the student, an attitude which was aggravated by the representative of the College of Physicians, who defied the Council. The Council, however, were not intimidated by this disloyal action on the part of the English Conjoint Board, and supported the views of the Education Committee.

11. The number of members of the Penal Cases Committee has been increased by the addition of Sir Christopher Nixon, Dr. Bruce, and himself.

Mr. Horsley concluded with some remarks on Council finance, which, he alleges, is in a serious state. If the accounts of the pharmacopœia were separated as they ought to be (and as at the last session of the Council it was finally determined that they should be), and a true estimate obtained of the finances of the Council, it would become clear that the income is diminishing, while the expenditure is increasing, that the reserves of the various branches are also decreasing, and that the Irish branch is already bankrupt. The proposal was made by the junior treasurer that money should be lent from the funds of the English branch to the bankrupt Irish branch, but this provisional and unsound proposition fortunately met with no support from the Council. The whole trouble of the Irish branch arises from the fact that the financial system of the Council and its branches is faulty. The necessary expenditure of the branches imposed upon them by the Medical Act of 1858 is by the same Act only to be met by such registration fees as happen to be paid into the account of that particular branch Council, the result being that if, as is the case, the students educated in Ireland to a considerable extent register themselves in England and Scotland, the Irish Branch of the Council is deprived of its proper income. The whole constitution of the Council and its Branch Councils and their financial arrangements therefore need immediate revision, and this fact alone, in Mr. Horsley's opinion, constitutes a powerful argument for obtaining as quickly as may be an amendment of the Medical Acts. A committee, however, which was proposed by Dr. Glover to consider amendment of the Medical Acts was refused by what Mr. Horsley describes as "the customary clique of obstructionists," headed as usual by Mr. Carter, and in the discussion upon Mr. Glover's motion, the same obstructionists suggested that all propositions for a Medical Amendment Bill should come from the outside.

Summarising the work of the last session of the General Medical Council, the profession, Mr. Horsley observes, can be fairly congratulated on the fact that at this last session the majority of the questions raised for discussion not only have been accredited sufficient time for their consideration, but also that the interests of the profession have obtained on the whole nearly as much consideration as the interests of the general public.

Medical News.

Edinburgh University Scholarships and Prizes.

At the Graduation Ceremonial last week, the following Scholarships and Prizes in the Faculty of Medicine were awarded:—The Ettles Scholarship—William John Barclay, B.A., M.B., Ch.B. The Beane Prize in Anatomy and Surgery—Arthur Preston, M.B., Ch.B. The Syme Surgical Fellowship—Carol Hendrik Kruger, M.D., C.M. The Goodsir Memorial Fellowship—Percy Theodore Herring, M.D., C.M. The Mouat Scholarship in Practice of Physic—John Jeffrey, M.B., Ch.B. The Murchison Memorial Scholarship in Clinical Medicine—Alfred Charles Sandstein, M.B., Ch.B. The Gunning Victoria Jubilee Prize in Zoology—James Peter Hill, B.Sc. The Gunning Victoria Jubilee Prize in Pathology—William Thomas Ritchie, M.D., C.M. The Pattison Prize in Clinical Surgery—Ernest Francis Bashford, M.B., Ch.B., and Hubert Dunbar Shepherd—equal. The Buchanan Scholarship in Gynecology—William John Barclay, B.A., M.B., Ch.B. The James Scott Scholarship in Midwifery—Frederick Adolphus Fleming Barnardo, M.A., M.B., Ch.B. The Cameron Prize in Therapeutics—Major David Bruce (R.A.M.C.), M.B., C.M. Edin., for his discoveries of the cause of Malta Fever and of the Tyetse Disease, and the great value of these discoveries in their prevention and treatment.

Voyage d'Instruction.

THE circular trip, organised to leave Nérès on September 2nd to visit the best known French watering-places, to which we have previously called attention, will be under the superintendence of Professor Landouzy. Starting on September 2nd the party, which is open to medical men and students of all nationalities, will visit La Bourboule, Mont Dore, St. Nectaire, Royat, Durtol, Châtel Gayon, Vichy, Bourbon, l'Archambault, and St. Honoré winding up on September 13th by a visit to Pougues. Arrangements have been made to secure half fares for intending members to and from the rendezvous (Nérès). The cost is fixed at 200 francs (£8) per head exclusive of travelling and hotel expenses, luggage, tips, carriages, &c. Subscriptions are received up to the 15th inst. by Dr. Carron de la Carrière, 2, rue Lincoln, Paris.

Apothecaries' Hall of Ireland, Examinations.

THE following gentlemen have passed:—In Biology: E. A. Reilly. Physiology: A. J. Barnes, H. W. Mason. Medical Jurisprudence: Stafford Adye-Curran, S. W. Battle, M. A. O'Carroll, James Barnes. Hygiene: S. W. Battle, James Barnes. Pathology: S. W. Battle, James Barnes, A. Thompson. The following completed the Third Professional Examination: A. J. Barnes, S. W. Battle, A. Thompson, M. A. O'Carroll. Passed in Ophthalmology: William Harding, Frederick Bass, S. W. Battle, Patrick O'Neill. Passed in Midwifery: William Harding, M. O'Carroll, S. Battle, Patrick O'Neill. Passed in Surgery: M. O'Carroll, S. Battle, Patrick O'Neill, H. Bass. Passed in Medicine: M. O'Carroll, S. Battle, Patrick O'Neill. The diploma was, therefore, granted to the following candidates, entitling them to practise medicine, surgery, and midwifery: M. O'Carroll, S. Battle, Patrick O'Neill.

Apothecaries' Hall of Ireland.

AT the annual meeting of the governor and council of the Apothecaries' Hall of Ireland, held on August 1st, the following were duly elected for the ensuing year:—Governor: James Raverty, L.R.C.S.Ed.; Deputy Governor: Hugh A. Auchincloss, F.R.C.S.I. Directors: F. G. Adye-Curran, F.R.C.S.I., M.D., Dublin University; John Evans, L.R.C.S.I.; W. V. Furlong, L.R.C.S.I.; F. D. Finucane, M.D.; J. A. Johns, M.B.; Robert Montgomery, M.R.C.S.Eng.; Robert J. Montgomery, M.B., F.R.C.S.I.; R. G. O'Flaherty, M.B.; Christopher O'Brien, M.B.Dur.; James Shaw, L.R.C.S.I.; J. S. Stritch, L.F.P.I.; S. M. Thompson, L.R.C.S.I.; C. R. C. Tichborne, LL.D., L.R.C.S.I. Representative on the General Medical Council: C. R. C. Tichborne. Secretary: Robert Montgomery, M.R.C.S.

Notices to Correspondents, Short Letters, &c.

ORIGINAL ARTICLES or LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

A MOULDED BED-PAN.

A CORRESPONDENT asks for the address of the manufacturer of a special form of porcelain bed-pan, the upper part whereof is moulded to the form of the parts with which it comes into contact. We are unable to trace the notice which originally led him to purchase it, but possibly some of our readers can assist him.

M. R.—We will endeavour to fall in with your suggestion at an early date, but there is too much pressure on our space at present to allow of our doing so forthwith. You shall be communicated with in due course.

CRITIC.—It would be unjust to blame the persons whose lineaments have been reproduced without authority. There is no law to prevent a newspaper publishing what purports to be a portrait, even in the event of the latter being a gross libel, from an æsthetic point of view. It is one of the penalties of greatness, and also of notoriety, to be liable to be caricatured.

THE LIMITS OF COMPETITION.

According to the *Daily Mail*, a dispensary has just been opened in Stepney, and the prices set forth on the usual card in the window range as follows:—

Medicine for the Working Classes.	
Advice and medicine	4d.
Advice and medicine for the week	1s.

This is certainly cutting it fine! We presume the patients furnish the bottles and corks.

A. T. S.—A chemist is required to dispense the exact product mentioned in the prescription, that is to say, the product of the particular brand or mark designated, and not a presumed chemically identical product. To do otherwise would be to incur a charge of fraudulent substitution.

Vacancies.

- Ancoats Hospital, Manchester.—Resident Junior House Surgeon. Salary £50 per annum, board, &c.
- Birkenhead Union.—Assistant Medical Officer for the Infirmary Workhouse and Schools. Salary £80 per annum, with board, washing, and apartments, but no extra fees. The Clerk to the Guardians, Birkenhead.
- Cheltenham General Hospital.—Assistant House Surgeon for two years, unmarried. Salary £100 per annum, board and lodging.
- County Asylum, Gloucester.—Junior Assistant Medical Officer, unmarried. Salary commences at £120 per annum, rising £10 yearly to £150, board (no stimulants) and washing.
- Dundee Royal Lunatic Asylum.—Medical Assistant. Salary £100 per annum, with rooms, board, and washing.
- General Hospital, Nottingham.—Assistant House Physician for twelve months. Salary £50, board, lodging, and washing in the hospital.
- Guy's Hospital Medical School, London, S.E.—Lecturer on Biology; also Demonstrator of Chemistry and Physics. Apply the Dean.
- Hospital for Consumption and Diseases of the Chest, Brompton.—Assistant Resident Medical Officer. Salary £100 per annum, board and residence. Also Resident House Physician for six months. Honorarium of £25 each.
- Lunatic Hospital, The Coppice, Nottingham.—Assistant Medical Officer, unmarried. Salary £150 a year, apartments, board, attendance, and washing.
- Macclesfield Infirmary. Junior House Surgeon. Salary £70 per annum, with board and residence.
- Metropolitan Asylums Board.—Assistant Medical Officer, *pro tem.*, at the Leavesden Asylum, near Watford, Herts. Salary £3 3s. a week with the usual residential allowance. Apply Medical Superintendent.
- Miller Hospital and Royal Kent Dispensary, Greenwich Road, S.E.—Junior Resident Medical Officer for six months. Salary at the rate of £40 per annum, board, attendance, and washing.
- Royal Hants County Hospital, Winchester.—House Surgeon, unmarried. Salary £65 per annum, rising to £75, with board, residence, &c.
- Seamen's Hospital Society (*Dreadnought*), Greenwich.—Senior House Surgeon for the Branch Hospital in the Royal Victoria and Albert Docks, E. Salary £75 per annum, with board and residence and an additional £25 per annum if certain clinical work is performed satisfactorily.
- St. Luke's Hospital, London, E.C.—Clinical Assistant for six months. Board and residence provided.
- St. Pancras and Northern Dispensary, 126, Euston Road, London.—Resident Medical Officer, unmarried. Salary £105, residence and attendance. Hon. Sec., 23, Gordon Street, W.C.
- University of Durham College of Medicine, Newcastle-upon-Tyne.—Lecturer in Midwifery and Diseases of Women and Children.
- Victoria Hospital for Children, Queen's Road, Chelsea, S.W., and the Victoria Convalescent Home, Broadstairs.—House Surgeon for six months. Honorarium at the rate of £50 per annum, board and lodging in the hospital.
- West Kent General Hospital, Maidstone. Assistant House Surgeon for six months. Honorarium at the rate of £50 per annum, with board and residence.
- Westminster Hospital.—Pathologist. Salary £250 per annum, and £80 per annum will be allowed for expenses, including the services of an Assistant.

Appointments.

- AITEEN, W. L., M.B., Ch.B.Melb., Acting Officer of Health for the City of South Melbourne, Victoria, Australia.
- BEGG, WM., M.B., Ch.M.Edin., Officer of Health for Waihalla Shire, Victoria, Australia, vice W. A. Forsyth, resigned.
- BLACK, L. P., M.B., B.C.Camb., L.R.C.P.Lond., M.R.C.S., Medical Officer to the Rural District Council, Braintree.
- BUTLER, JAMES, M.B., C.M.Glasg., Senior Assistant Medical Officer, Govan District Asylum, Hawkhead, vice Francis O. Simpson, resigned.
- CROWTHER, E. E., L.R.C.P., L.R.C.S.Edin., L.F.P.S.Glasg., Medical Officer for the Luddenden Sanitary District of the Halifax Union, vice Thomas Crowther, resigned.
- CUPPAIDGE, JOHN LOFTUS, M.D., B.Ch.Dubl., Medical Officer to the Totnes Cottage Hospital.
- GIBSON, GEORGE JOHN, M.D., M.Ch.Irel., Medical Officer to the Totnes Cottage Hospital.
- GUNTHER, H. A., M.B., House Surgeon to the Great Northern Central Hospital, Holloway Road, N.
- HAINS, L. J. CART, L.R.C.P., L.R.C.S.Edin., J.P., Medical Officer to the Totnes Cottage Hospital.
- HORDER, THOMAS J., M.B., B.Sc.Lond., Physician to Out-Patients at the Great Northern Central Hospital, Holloway Road, N.
- JOHNSON, S., M.D., M.Ch.Irel., Medical Officer to the Town Council, Stoke-on-Trent.
- MILES, W. ERNEST, F.R.C.S.Eng., Assistant Surgeon to the Cancer Hospital (Free), Brompton, and also Surgeon to Out-Patients to the Gordon Hospital for Diseases of the Rectum, London.
- MUSPRATT, E. L. C., L.S.A., F.C.S., Resident Medical Officer of the Wolverhampton Medical Association in succession to W. S. Mercer.
- PARSONS, WALTER BROCK, M.B.C.S., L.R.C.P.Lond., Junior House Surgeon to the North-West London Hospital, Kentish Town Road, N.W.
- PURVIS, W. PRIOR, B.Sc., M.D., M.S.Lond., F.R.C.S.Eng., Surgeon-in-Charge of the Ear and Throat Department of the Royal South Hants Infirmary, Southampton.
- RENTSCH, S. HENRY, L.R.C.P.Lond., M.R.C.S., Medical Officer for the South District of the Stratton (Cornwall) Union, vice A. H. Minton, resigned.
- SMITH, K. RAWLINGS, M.D., B.S.Lond., M.R.C.S., L.S.A., Medical Officer to the Totnes Cottage Hospital.
- SMITH, F. W., L.R.C.P.Lond., M.R.C.S., Medical Attendant to the men in the employ of the St. George's Vestry, St. Saviour's Union, London.
- SOUTHWELL, C. E., L.R.C.P., L.R.C.S.Edin., L.F.P.S.Glasg., Assistant Medical Officer to the Town Council, Stoke-on-Trent.

Births.

- CAZALET.—On July 29th, at Grey Friars Green, Coventry, the wife of Grenville W. Cazalet, L.R.C.P.Lond., M.R.C.S., of a son.
- COWNIE.—On July 28th, at 89, Severn Road, Cardiff, the wife of James F. Cownie of a daughter.
- EDELSTEN.—On July 29th, at Brixton Road, S.W., the wife of Ernest A. Edelsten, M.A. M.B.Oxon., of a daughter.
- FRASER.—On July 22nd, at Epworth, St. Edward's Road, Southsea, the wife of A. Mearns Fraser, M.B., of a daughter.
- GOODCHILD.—On July 30th, at Highgate Road, N.W., the wife of N. John Goodchild, M.R.C.S.Eng., L.R.C.P.Lond., of a son.

Marriages.

- GUTHRIE—POWER.—On July 26th, at Frant Church, Thomas Clement Guthrie, M.B., to Norah, second daughter of Sir William Tyrone Power, K.C.B., of Kilmore, Tunbridge Wells.
- MOFFAT—VAVASSEUR.—At Knockholt Parish Church, on the 3rd inst., by the Rev. Havard Jones, M.A., rector, Robert Unwin Moffat, C.M.G., M.B., C.M., to Hilda, youngest daughter of J. Vavasseur, Esq., of Knockholt, Kent.
- SIMPSON—BARBOUR.—On July 26th, at St. Alban's Church, Tattenhall, Cheshire, G. F. B. Simpson, M.B., Ch.B., second son of Professor Simpson, M.D., Edinburgh, to Caroline Elizabeth, eldest daughter of George Barbour, of Bolesworth Castle, Cheshire.
- WILLIAMS—HARVEY.—On August 3rd, at the Parish Church, Hampstead, by the Rev. Burchell Herne, Alfred Henry Williams, M.D., of Harrow, third son of the Right Rev. the Bishop of Walapu, N.Z., to Lucy Caroline Simpson, second daughter of Captain Frederick Harvey, B.N., of Hampstead.

Deaths.

- EVEZARD.—On August 1st, Edward D'Arcy Evezard, of Regent Cottage, Broadstairs, retired Surgeon Major of Her Majesty's Madras Army, in his 70th year.
- KEENE.—On July 31st, at Merton House, Grantchester, Cambridge, Frederick Joseph Keene, L.R.C.P.Lond., M.R.C.S.Eng., L.S.A., aged 68 years.
- PILLEAU.—On July 28th, at Brighton, Henry Pilleau, R.I., Deputy Inspector-General of Hospitals, of Kensington Court Mansions, W., aged 86 years.

Paris Clinical Lectures.

PYREXIA DURING CONVALESCENCE FROM TYPHOID FEVER

By PROFESSOR POTAIN,
Of Paris

[FROM OUR FRENCH CORRESPONDENT.]

I RECENTLY called your attention in the Piorry Ward, to a young woman who was admitted to the hospital suffering from typhoid fever. We hesitated for a time as to the diagnosis, especially as this patient, a Dutch woman, understood no French, and by reason of the malady was plunged into a state of extreme prostration. At the end of a few days all doubt was removed by the appearance of lenticular rose spots on the abdomen. The fever followed the usual course, and about the fifteenth day the normal temperature was attained and everything led to believe that the patient had entered on convalescence. One evening, however, the temperature rose and oscillated for several days between 102 degs. and 104 degs. F. What could have been the cause of this increase of the temperature in the course of convalescence from typhoid fever? That is the question I wish to examine with you to-day.

You know that in typhoid fever the temperature follows, at first, a regular ascensional movement; it then remains a few days stationary, and finally it gradually falls, returning to normal, in uncomplicated cases, towards the twenty-first day; the temperature not unfrequently falls for a few days below the normal. Now, there are a certain number of causes which may interfere with the classical curve of the temperature absent during convalescence. First there are cases where the thermometer is seen to go up suddenly two or three degrees above the normal level. This rise, which may persist four or five days, coincides with the change from liquid to solid food. It is what is called the *febris carnis*, and has but little significance.

In other cases, the temperature creeps up gradually until it attains the height observed at the outset of the malady, and a second crop of lenticular rose spots are not unfrequently observed in such cases. I proposed to apply the term *reiteration* to this phenomenon in order to distinguish it from relapses, with which it is so frequently confounded. Relapses which really deserve that name are the result of a fresh infection, while reiterations, on the contrary, simply continue the work of the primary infection. Two or three successive reiterations can be observed. I myself have witnessed four consecutively of gradually decreasing severity. The distinction between reiterations and relapses is very important, because the former are generally very benign, while the latter are frequently fatal. In some convalescents the fever reappears under a paroxysmic form, called by the Germans *nach-fieber*, or *secondary fever*. It sets in without any apparent cause, and the temperature may rise from one to three degrees for some days, sometimes insulating the march of intermittent fever, the paroxysms being separated by an interval of two or three days of normal temperature.

Among the latent accidents capable of causing a rise of temperature in convalescents from typhoid fever, constipation takes the first place; it would seem at first that the intestine ought to empty itself easily after a malady, of which diarrhoea was one of the principal symptoms. Yet in convalescence from typhoid constipation of an obstinate character is observed, producing tympanitis and fever. In such cases attention is immediately drawn to the constipation, and the diagnosis is rendered easy, as indeed is the treatment. On the other hand, the fever may be the result of chronic enteritis usually localised in the small intestines, and generally provoked by ill-advised diet. The cause of the return of the fever may also be due to disturbances of the liver or kidney. There is no organ in fact that may not be affected more or less during convalescence from typhoid fever. Thus the lungs may become the seat of various lesions, acute bronchitis, broncho-pneumonia, tuberculosis, &c. It has been asserted that patients who entered the hospital for typhoid fever have there contracted tuberculosis, but such a statement is an exaggeration, to put it mildly. No doubt pulmonary phthisis does sometimes appear during convalescence from typhoid, and it is obviously difficult to affirm positively that hospital infection was not the cause, but for my part I have never witnessed chronic tuberculosis developing under these conditions, except in patients who had displayed indubitable signs of the malady on admission to hospital. Hospital infection is less improbable when the complication takes the form of acute tuberculosis; I have observed several cases of this kind. In one of them I found, at the autopsy, two varieties of ulceration, one appertaining to the usual lesions of typhoid fever while the other was distinctly tuberculous as proved by the presence of Koch's bacilli.

You all know how frequently suppuration follows typhoid fever, sometimes it develops insidiously, but more frequently it determines a rise of temperature in the convalescent patient. These suppurations may present themselves in regions very far apart, muscles, larynx, thyroid body, osseous system, &c. This concludes what I have to say on this occasion concerning the accidents susceptible of provoking a return of the fever. These complications are sometimes due to the presence of the bacilli of Eberth, alone or in association with other microbes; frequently they are the result of secondary infection. There are also cases in which the fever might be called idiopathic since the cause cannot be discovered, and this is the case in respect of the patient who is the subject of this lecture.

AN OPERATION FOR HAMMER-TOE.

By J. JACKSON CLARKE, M.B., F.R.C.S.,

Surgeon to Out-patients at the North-West London and City Orthopaedic Hospitals.

OPERATIVE treatment in cases of hammer-toe is only required when the deformity is fixed to a greater or less extent. When the affected toes can be readily straightened by the surgeon's fingers, instrumental treatment will suffice to correct the condition. If the degree of fixation is but slight, Adams's subcutaneous operation, as practised in the right second

toe of the patient whose case is given below, is all that is necessary. If, again, the degree of fixation is great, it points not only to shortening of the lateral and plantar ligaments of the joint or joints concerned, but also to shrinking of the skin on the under side of the toe. For such a toe, either excision of the head of the proximal phalanx of the affected joint through a lateral incision (Anderson's operation); or cutting through all the soft parts: skin, tendons, and ligaments, on the flexor side of the affected joint and leaving the open wound that remains when the toe is straightened to granulate up (Petersen's operation) must be practised if a satisfactory result is to be obtained. Both these operations, in different ways, allow for shortening of the skin on the plantar aspect of the toe, but neither of them makes provision for the wrinkling-up of the skin that occurs on the dorsal aspect of the affected joint when the toe is brought straight. This skin, as is shown in the accompanying illustration, is the seat

Schematic drawing of a Hammer-Toe, showing the incisions recommended by the Author.

of a painful corn and usually covers an adventitious bursa. When the previously deformed toe has been straightened out after operation and placed upon a small splint the tension in the altered skin on the dorsal aspect of the joint gives rise in my experience to a degree of pain out of proportion to the extent of the operation. In order to obviate this I have designed the following modification of Anderson's operation:—Two slightly curved incisions meeting over the lateral aspects of the affected joint, see figure, are made to include the area occupied by the corn. This portion of skin and the subjacent bursa are removed. The joint is now opened by cutting through the expansion of the extensor tendon and the synovial membrane, and an elliptical portion of these corresponding to, but smaller than, the piece of skin already removed is cut off. The head of this proximal phalanx is freed by division of the attachments of the lateral ligaments, and is removed by bone forceps after being grooved transversely by a fine saw. The toe is then straightened and the dorsal tendon and synovial membrane are reunited by a catgut stitch. The wound in the skin is finally closed by two fine silk-worm-gut stitches. As an example of the operation I may give the following case:—

D. G., æt. 20. Second toe on the left foot is sharply and rigidly bent at the first interphalangeal joint. There is a corn over the prominent head of the first phalanx. The right second toe is bent to a right angle at the terminal joint. The deformity on the right side can just be corrected by force. Both great toes show a moderate amount of hallux-valgus. The patient has had "rheumatism," and has been operated on for nasal obstruction, due to thickening of the inferior turbinate bodies. Several members of the family have had rheumatic gout. The condition of the toes has been noticed for five years, and for the last two years the second left toe has been the seat of much pain, interfering greatly with the patient's pursuits. The right second toe has not caused any discomfort.

I performed the operation described above on the left side. There was no pain after it, and the patient slept well on the evening of the operation. The toe was readily straightened without any tension. A few days later I operated on the second toe of the right side by Adams's method. I made a simple puncture with a sharp tenotome at the middle of the flexion-crease of the terminal joint and then introduced Muirhead-Little's small hammer-toe knife and divided the lateral ligaments, the anterior ligament, and the flexor tendons avoiding the digital vessels and nerves. The toe came readily straight after this, and the patient said he felt no pain either during the operation (which was done under cocaine anaesthesia) or subsequently. On the 9th day the toes were dressed, and on the 14th the patient was able to put on the boots I had had made for him. A week later he was able to leave for the seaside, being able to walk about comfortably.

Comments.—It is hardly necessary to point out that before any operation is done upon the toes the corns should, for at least a week, be treated with the salicylic acid (5j), ext. cannabis ind. (gr. xv.), and collodion (5j) application. For at least two days before operation the feet should be frequently scrubbed, and at intervals enveloped in compresses of 1–50 carbolic lotion. A stronger (1–40) compress being applied for one hour before operation.

THE CAUSES OF COUGH IN CHILDREN,

WITH RELATION TO DIAGNOSIS AND TREATMENT. (a)

By J. P. PARKINSON, M.D., M.R.C.P.Lond.,
F.R.C.S.Eng.

I WISH to deal with the causes of cough entirely from the clinical aspect, and with a view to diagnosis, and consequently effective treatment, and I wish to lay stress upon the frequency of cough due to other causes than those affecting the respiratory organs.

For this purpose I have collected 700 consecutive cases occurring in children, aged from 6 months to 12 years, in which cough was the chief or a very prominent symptom complained of. In all these the chest was carefully examined, and any case in which the symptoms could be interpreted as due to disease these are included. The results are as follows:—

Cases.	Cases.
Acute or chronic enlargement of the tonsils ... 170	Rickets ... 23
Bronchitis varying in amount ... 143	Whooping-cough ... 23
Constipation ... 69	Acute pneumonia ... 18
Gastric enteritis ... 58	Broncho ... 11
Adenoids (well marked) ... 58	Simple dry pleurisy ... 8
Pharyngitis ... 51	Laryngismus Stridulus ... 3
Worms (chiefly threadworms) ... 30	Laryngitis ... 2
Tuberculosis of lungs ... 29	Mixed causes as pleural effusion, pleural adhesion, lymphadenoma, dental caries, &c. ... 12

Analysing these cases further, it will be seen that 215 cases were due to various respiratory troubles, 160 cases were due to digestive or intestinal disturbances, 279 were due to throat conditions, or in percentages:—Due to chest diseases, 31; gastro-intes-

(a) Read before the British Medical Association (Medical Section) August 3rd, 1899.

tinal causes, 23; throat conditions, 40; and other causes, 6.

Now as regards diagnosis, taking first the most frequent cases, viz., those due to throat conditions. In these the cough is often very severe, generally worse at night, and sometimes only occurring at that time, or it may occur in paroxysms after talking, &c. The cough is not uncommonly followed by vomiting, and sometimes, especially if adenoids are present, by epistaxis.

By far the commonest cause of throat cough is enlargement of the tonsils, accompanied by more or less inflammation, and often some surrounding pharyngitis; in many of these cases adenoids are also present. On examining the chest one generally finds some rough breathing and an occasional rhonchus, which no doubt leads often to a diagnosis of slight bronchitis, but treatment applied to this condition will not effect a cure if the condition of the tonsils be disregarded. The tonsils may be acutely inflamed or enlarged, and congested, or simply enlarged, as a result of frequent previous inflammations, and in the latter case removal is the only treatment likely to be of permanent benefit.

This cause of cough is specially frequent in children between the ages of six and twelve, and accounts for nearly a quarter of the cases. Well marked adenoids were present in 58 cases or about 1 per cent., and no doubt in many other cases they were present, but did not give such clear symptoms, in these cases the cough is often followed by vomiting of mucus and sometimes blood, and deafness and otitis media are of frequent occurrence. The development of the chest is interfered with, and there is often seen an inspiratory recession of the lower yielding part of the thorax, showing the interference with respiration and the necessity of active treatment.

A preliminary course of tonics such as iron and cod liver oil may be tried, and sometimes I have found much benefit from the nasal injection of an alkaline astringent lotion such as the following:—

Acid carbolic, gr. 1;
Acidi tannici, grs. 20;
Sod. bicarbonate, grs. 40;
Glycerine, 5 ij;
Aque ad, 3 iv;

to be injected into the anterior nares occasionally during the day, but I cannot say the result of this treatment is very striking in the worst cases, the symptoms usually continue, and then the removal of the adenoid vegetations is indicated. Of course, I refer only to cases where symptoms are produced by the vegetations, for there is no doubt they are frequently present, and cause no ill effects.

In 51 cases general pharyngitis was present and appeared to be the cause of the cough as this symptom was removed by its cure.

In a few other cases laryngitis with or without laryngismus stridulus was the cause. Retro-pharyngeal abscess sometimes occurs in infants a few months old, and the symptoms resemble those of enlarged tonsils: there is more commonly a kind of snuffles than an actual cough. It is easily seen when the fauces are examined.

The next set of cases producing cough are lung diseases of which bronchitis is by far the most frequent, accounting for 143 cases, or about 20 per cent. of the total number of children. Twenty-nine cases were due to lung tuberculosis, and the same number to pneumonia, of which more than half were of the lobar type. This frequency of lobar pneumonia in young children seems only to have been recognised of late years, though the type of the disease is usually well marked, and the prognosis much better than in broncho-pneumonia.

A few cases were due to pleurisy, dry or moist,

bronchiectasis, enlargement of the mediastinal glands, &c., &c.

The kind of cough in these last two cases may exactly resemble whooping-cough, consisting of a series of expiratory efforts, separated now and then by a whooping inspiration and often accompanied by vomiting or epistaxis and other hæmorrhages; such cases may be easily mistaken for pertussis. The chief points to which attention should be directed are the following:—

First, there may be a previous history of whooping-cough; this is a disease which rarely occurs more than once, though for a few months the whoop may return, if the child have a cough.

Secondly, examination of the patient may show signs suggesting bronchiectasis, as cyanosis, clubbing of the fingers with deformity, or dulness in the chest and râles here and there. The sputum is generally described as offensive, but, as pointed out by Eustace Smith may or may not be so, it may be in large quantity often brought up at considerable intervals.

If enlargement of the bronchial glands be present there may be dulness between the scapulæ about the level of the fourth or fifth dorsal vertebrae, or sometimes in front over the manubrium sterni. Also occasionally there may be stridor or harsh or deficient breath sounds on one or other side of the chest, usually on the left side.

I have recently had two cases of this condition under my care at the North-Eastern Hospital for Children. In both cases the symptoms were much the same.

Both children had had whooping-cough some years previously, and had not been well since, suffering from chronic cough.

CASE 1.—A child, æt. 6, had a chronic cough followed by occasional vomiting, and often blood in the sputum. He was pale and thin, fingers markedly clubbed. The left side of the chest was smaller than the right and moved less well; there was moderate dulness front and back, and the breathing was obscured by numerous moist sounds. On the right side there was some impairment to percussion at the base with harsh breathing and numerous râles. The other organs appeared normal. There was no excess of dulness behind the sternum or between the scapulæ. The child died a week after admission, and at the necropsy the left lung was found markedly restricted, the lung tissue condensed, and the bronchi uniformly dilated and filled with a muco-purulent fluid. The left bronchus was slightly compressed by a mass of caseous glands behind and above the root of the left lung, which glands by their proximity to and irritation of the vagus had probably produced the peculiar cough. The other organs were fairly normal. The second case was but a repetition of the first, except that the bronchiectasis was absent and merely the enlarged bronchial glands present.

The third class of cases in which cough is a frequent and prominent symptom are the gastro-intestinal cases. They include about 23 per cent. of the whole. I have, of course, excluded from this group all cases in which there was any obvious disease of the throat or lungs. It is worth while to lay stress on the presence of cough as a marked symptom in many cases of gastro-intestinal troubles as a considerable number of these children had been already treated before they came to the hospital as cases of cough due to lung disease, and the diarrhoea was looked upon as secondary, a state of things which is, of course, very frequent in bronchitis or broncho-pneumonia, or tuberculosis, owing to the irritation of swallowed sputum.

The cough is frequent but not very severe, and in some cases only occurs at night.

The remaining 6 per cent. of cases were due to various causes, in many rickets was present, a con-

dition which is well known to predispose to reflex nervous disturbances, and in a few cases the cough was not relieved till numerous carious teeth were filled or extracted.

I have not alluded to ear troubles as a cause of cough, for I was not able to satisfy myself that the cough was not due to the throat disease, which in children seems to be an almost invariable accompaniment of ear disease in children.

THE EVOLUTION OF THE SCIENCE OF OTOTOLOGY. (a)

By PROFESSOR URBAN PRITCHARD,

President of the International Congress of Otology, &c.

I CANNOT do better, for the purpose of inaugurating this congress than select for my subject the story of the birth and growth of otological science. Although Toynbee was generally acknowledged to be the father of modern otology, for the date of its birth we must go back some 3,400 years to the then flourishing country of Egypt. For Professor Roosa, in his excellent treatise, referred to a certain ancient papyrus (called, after its discoverer, the Papyrus Ebers) on which was written a monograph on "medicines for ears hard of hearing" and "for ears from which there is a putrid discharge." And there, in their museum, might be seen a confirmation of the fact that ear troubles not only existed in those days, but that they could be cured; for they had the good fortune to possess a curious old Egyptian relic, consisting of a wooden tablet on which were portrayed, in bas relief, two effigies of the sacred bull and two auricles; this was undoubtedly a votive offering to the god Hathor from some "grateful patient." In spite of its early birth, however, otology, except perhaps with regard to its anatomy and physiology, did not make itself of great importance until the second half of the present century. The Royal Ear Hospital in Dean Street, Soho which is acknowledged to have been the first successful aural clinique in Europe—and we believe in the world—was established in 1816. But, speaking generally, we may safely assert that aural surgery continued to be more or less in the stage of infancy until between 1840 and 1860, when the study was vigorously taken up by Sir William Wilde and Toynbee, who thus gave a fresh impetus to the study of the pathology and treatment of diseases of the ear. Even then its importance was by no means generally recognised; indeed, only thirty years ago it was a favourite saying of more than one celebrated surgeon that "ear diseases may be divided into two classes—those which can be cured by any general practitioner and those which, being incurable, may be relegated to the tender mercies of the ear specialist." In my student days I well remember the sarcastic manner of Professor Partridge when he said, "Ah, gentlemen, a little wax is a godsend to an aurist," meaning, of course, that its removal was an easy method of earning a reputation. And, no doubt, there was a certain truth in those words, though not exactly in the sense implied by the good old professor; for which of us had not found that, by removing a plug of cerumen which had either not been diagnosed or which had resisted all the efforts of the general practitioner to dislodge it, he has gained *kudos* and an appreciation which many of his more delicate operations had failed to secure? Things had indeed changed since then, for instead of a few aural surgeons scattered here and there in Great Britain, we had now at least a couple of hundred, while the number of clinics in London alone had been in-

creased from two or three to near upon twenty. And in many other countries this branch of medical science was even more strongly represented. As a natural result of the increased interest in the work, I would call attention to the unique museum connected with that congress, wherein was to be found the largest and most valuable collection of otological specimens, a collection which could only have been brought together by the union of international forces. The museum is so complete that if you had come to visit it alone your trouble would have been repaid. But in one respect there is still room for improvement. I refer to the need for the better recognition of otology by our universities and colleges. One step has lately been made in this direction, for the University of Edinburgh has now made it one of the qualifying subjects for her medical degrees. So far as the anatomy and physiology of the auditory apparatus were concerned comparatively little has been added in the last thirty years to the store of knowledge already gained, although a more intimate study of its parts has made that knowledge more complete and precise. In pathology there has been considerable advance. In disease of the meatus, although aspergillus was discovered before this period by Meyer, Schwartz, and Wreden, yet it was not elaborated with any fulness until later. Also, the nature and classification of exostoses had been worked out within this period. Our knowledge of the changes in chronic middle-ear catarrh, and in sclerosis, has considerably advanced, although much here yet remains to be done. The effect of pathological conditions of the nose and nasopharynx upon the auditory apparatus, adenoid vegetations more especially, has practically been discovered. In chronic suppurative catarrh, disease of the ossicles, the implication of the attic, the antrum, and the mastoid cells has been worked out; also the intercranial complications which sometimes follow. The nature of the granulations and polypi are now better understood, and, although Toynbee had already called attention to cholesteatoma, its pathological importance in connection with mastoid disease was not fully realised until quite lately. In the pathology of labyrinthine disease there has not, perhaps, been so much advance; but Menière's disease is now better understood, and Politzer has made known a disease of the bony capsule. Finally, the pathology of congenital syphilis affecting the internal ear has been partially worked out. The means of diagnosis have been considerably improved, while in treatment there have been immense strides due to the adoption of antiseptic surgery. The 19th century, which has brought to the world so many wonderful blessings in other directions has not been unmindful of their branch of medical science. For, whereas at its commencement the ear was regarded almost as a *terra incognita*, scarcely worth consideration except as the seat of one affection only—that which was generally known as "a deafness"—now, at its close, this organ was fully-explored ground, and has been proved well worth the exploration. Otology has been raised from the rank of pseudo-quackery to an honourable position in scientific surgery, and its importance and bearing upon the body as a whole is now fully recognised.

DR. T. J. MONAGHAN, for twelve years Medical Officer of Health for the Borough of Accrington, has been presented by the mayor, councillors, and borough officials, with a tea and coffee service. "as a mark of personal respect and appreciation of services rendered" on his leaving for another sphere.

(a) Abstract of Inaugural Address at the International Congress of Otology, August, 1899.

A COUNTRY HERBALIST'S CURE FOR THE "KING'S EVIL." (a)

By JOHN KNOTT, M.A., M.D., and Dip. Stat. Med (Univ. Dub.); M.R.C.P.I., M.R.I.A.; &c., &c.

(Concluded from page 134.)

THIS chapter of the witty Andrew Boorde furnishes a convenient turning-point from which I proceed to make a new digression, for the purpose of taking notice of the curious and interesting practice of curing the King's Evil by Royal Touch.

Some sympathetic poet, whose name I have not preserved, penned the following lines, and also appears to have added the subjoined comment which I find in my common-place book:—

"THE TOUCHING FOR THE EVIL.

You have spoken light word of the touching of old,
But you never have heard of the good Angel-gold.

For it was not alone the Monarch's kind eye,
Nor the links that are gone, 'tween the low and the high
No, not for these only, though these they were much,
Came the stricken and lowly, to kneel to the touch.

The soft hand was put out, and the soft solace said,—
Few mourners could doubt their evil had fled.

For, evil it ceases, and sickness it goes
With broad golden pieces, and Nobles of rose.

Then when in their rest, in the stillness of night,
With their troubles redrest, and their burdens made
light.

Oh, blame not their blindness, 'twas the blindness of
love.

Made them think that this kindness, it came from
above.

And when 'twas thus given to those who had need,
That same thing of Heaven was Majesty's meed.

Then list to my warning, and cavil no more,
With light words and scorning, at the good forms of
yore.

"In the reign of the 'merry monarch,' the angel-gold, which was distributed by his Majesty's Almoners to those who came to be touched, amounted to £5,000 per annum. When the entire public revenue was under a million and a half pounds sterling, it must be allowed that this was a large sum to be distributed in one form of charity; and the historic fact may be held to prove that the second Charles Stuart possessed some better qualities than his Puritanical detractors would have us to believe. We may note that the sum so graciously expended amounted to £1,000 a year more than the combined salaries of the Secretaries of State, and was also £1,000 a year more than the allowance to Prince Rupert. But it is not so much its amount which almost makes a regret for this graceful superstition, as the direct communication it brought about, between the highest and the lowest, between the King and the Poor. If Royalty did but condescend to lower itself to a familiarity with the people it is curious that they will raise, exalt, adore it, sometimes even invest it with divine and mysterious attributes; if, on the contrary, it shuts itself up in an august and solemn seclusion it will be mocked and caricatured. This was one of the secrets of Napoleon's strength, and one of the secrets of Louis XVIIIth's weakness. If the great only knew what stress the poor lay by the few forms which remain to join them, they would make many sacrifices for their strength and preservation. Dr. Johnson—a man of the people, if there ever was one—was yet prouder of having been touched by Queen Anne, when he was a child, and of speaking about 'the great lady in black,' of whom he had an indistinct recollection, than he was of all his heroism under misfortune, or of all the erudition of his works."

The famous and loyal antiquarian scholar, Thomas Hearne, appears, from the evidence afforded by an

entrance in his Diary, to have been as orthodox in his faith regarding the efficacy of the Royal touch for the King's Evil as he was in the other articles connected with "privilege" and "legitimacy." "Yesterday, Mr. Gilman of St. Peter's parish in the east, Oxford (a lusty, heartick, thick, short man), told me that he is in the 85th year of his age, and that at the restoration of K. Charles II. being much afflicted with the King's Evil, he rode up to London behind his father, was touched on a Wednesday morning by that King, was in very good condition by that night, and by the Sunday night immediately following was perfectly recovered, and hath so continued ever since. He hath constantly worn the piece of gold about his neck that he received of the King, and he had it on yesterday when I met him."

It is interesting to note here that the custom of treating the King's Evil by the royal touch is mentioned by the Earliest English writer on medicine whose works have descended to us. Gilbertus Anglicus is made by Bale a contemporary of King John, while Freind argues from the internal evidence supplied by his own writings, that he was more probably coeval with King Edward the First. I quote from the English version of Freind's "Historia Medicinæ":—

"In treating of a strumous swelling in the glands he tells us that this disorder is otherwise called the King's Evil because Kings cure it. This account, however concise, from a Physician who seems not to have been led by any bias of interest, is sufficient to convince us, that the custom of touching, was very early introduced by our Kings; and from this author's manner of expressing himself, it is very plain, that he look'd upon it as a very ancient Practice. The French historians can trace up this usage of Touching in their own nation, by undoubted authorities, as high as the eleventh century, in the reign of Philip the First, but can give no account (which can be rely'd upon) how much more ancient it was: tho' some pretend to trace it as high, as Clovis. There is the like reason to think, even by this passage as well as by what is here and there hinted in our English history, that the same usage had, for some Centuries at least, prevail'd here; and they who carry it up as far as the time of Edward the Confessor, contemporary with Philip the First of France, seem to have good grounds for their opinion; at least I do not see any proofs, which can be brought against it. If the Monkish writers are supposed to be at all partial, and inclin'd to flatter the Crown, there are others, whose veracity cannot be called in question. Sir John Fortescue, a very learned and wise man, in his defence of the title of Lancaster, just after Henry the Fourth's accession to the Crown, represents the gift of healing as a privilege which had for time immemorial belong'd to the Kings of England: and he is so particular as to attribute this to the Unction of their hands, which is us'd at the Coronation: and therefore says, that Queens can have no such gift, because in this case that part of the ceremony is left out. However, we know Queen Elizabeth thought herself so much a King, that among other regal Functions she frequently exercised this. Archbishop Bradwardine who dy'd in 1348, and who appeals to the world for the cures performed by the royal Touch, uses, you will see, very strong expressions concerning the antiquity of it, which surely he would never have done, had it been so modern a practice, as some think it."

The following is the passage in Sir John Fortescue's "Defence of the House of Lancaster," to which Freind refers, and which he had found preserved in the Cotton Library. It will, I feel sure, interest all students of the history of our profession.

"Item Regibus Angliæ Regali ipso officio plura insumbant, quæ naturæ muliebri adversantur.—Reges Angliæ in ipsa unctione sua talem cælitus gratiam infusam recipiunt, quod per tactum manuum suarum unctarum infectos morbo quodam, qui vulgo Regius morbus appellatur, mundant & curant, qui alias dicuntur incurabiles. Item aurum & argentum sacris unctis manibus Regum Angliæ in die Paschæ Divinorum tempore (quemadmodum Reges Angliæ annuatim facere solent) tactum devote & oblatum, psmaticis & caducos curant; quemadmodum per annulos ex dicto auro seu

(a) An abstract of this paper was read in the Medical Section of the Royal Academy of Medicine in Ireland on Nov. 18th, 1898.

argento factos, & digitis hujusmodi morbidorum impositos, multis in mundi partibus crebro usu expertum est. Ruae gratia Reginis non confertur, cum ipse in manibus non ungantur."

The following extract from Archbishop Bradwardine's "Liber de causa Dei," contains the passage alluded to by our medical historian:—"Quicumque negas miracula Christiane, vini & vide ad oculum, adhuc istis temporibus in locis sanctorum per vicis miracula gloriosa. Vini in Angliam ad Regem Anglicum presentem, duc tecum Christianum quemcumque habentem morbum Regium, quantumcumque inveteratum, profundatum et turpem, & oratione fusa, manu imposita, ac benedictione, sub signo crucis data, ipsum curabit in nomine Jesu Christi. Hoc enim facit continue, & fecit sepiissime viris & mulieribus immundissimis, & catervatim ad eum ruentibus, in Anglia, in Alemania, & in Francia circumquaque; sicut facta quotidiana, sicut qui curati sunt, sicut qui interfuerunt & viderunt, sicut populi Nationum, & fama quam celebris certissime contestantur. Quod et omnes Reges Christiani Anglorum solent divinitus facere, & Francorum, sicut libri antiquitatum & fama regnorum concors testantur: unde & morbus Regius nomen sumpsit.

The first medical author who appears to have formally recommended sufferers from the King's Evil to have recourse to the Royal Touch when all the resources of his own profession had failed, was the diplomatic John of Gaddesden, whose famous "Rosa Anglica" still, fortunately, survives for the edification of professional posterity. This interesting treatise is coloured by the mysticism, and quaint—very often, indeed, loathsome—therapeutics, of the dark age in which it was produced. (The volume appeared somewhere between the years 1305 and 1315.) It is also distinctly redolent of professional avarice and unprincipled charlatanism. The wily John had "boo'd" himself into the position of Physician-in-Ordinary to the King, and his successful treatment of the heir-apparent to the Crown, while suffering from small-pox—by swathing him in scarlet, and draping his room so completely with the same material that only rays of that tint could penetrate to the patient—has contributed a well-known item to professional history. In the language of Freind: "John was no sooner at Court but he understood how to make a good Courtier, and pay his compliments in the best manner; and whenever a scrophulous case does not submit to the sovereign remedies, such as the blood of a weazel or Doves-dung, he exhorts the person immediately to apply to the King for the royal Touch." In the original of the "Rosa Anglica," "Si ista non sufficient, vadat ad Regem, ut ab estangatur & benedicatur—Valet tactus nobilissimi & serenissimi regis Anglicorum."

One of the phenomenal healers of the Annals of Unlicensed Medicine was our fellow countryman, Valentine Greatrakes, who, in Charles the Second's reign, performed "Severall marvillous cures by the stroaking of his hands." This practitioner's treatment would appear to have combined the properties and powers of the "Mesmerism" and the "Massage" of the present century. "He was born on the 14th of February, 1628, on his father's estate of Affane, in the County of Waterford, and was, on both sides, of more than merely respectable extraction, his father being a gentleman of good repute and property, and his mother being a daughter of Sir Edward Harris, Knt., a Justice of the King's Bench in Ireland. The first years of his school life were spent in the once famous Academy of Lismore; but when he had arrived at thirteen years of age his mother (who had become a widow), on the outbreak of the rebellion fled with him and his little brothers and sisters to England, where the fugitive family were hospitably entertained by Mr. Edmund Harris, a gentleman of considerable property, and one of the justice's sons. After concluding his education in the family of one John Daniel Getseus, a High-German minister of Stock Gabriel, in the County of Devon, Valentine returned to Ireland, then distracted with tumult and armed rebellion; and by prudently joining the victorious side, re-entered upon the possession of his father's estate of Affane. He served for six years in Cromwell's

forces (1650-1656) as a lieutenant of the Munster Cavalry, under the command of the Earl of Orrery. . . .

"When the Munster Horse was disbanded in 1656, Valentine retired to Affane, and for a period occupied himself as an active and influential country gentleman. He was made Clerk of the Peace for the County of Cork, a Register of Transplantation, and a Justice of the Peace. In the performance of the onerous duties which, in the then disturbed state of Ireland, these offices brought upon him, he gained deserved popularity and universal esteem. He was a frank and commanding personage, of pleasant manners, gallant bearing, fine figure, and singularly handsome face. With a hearty and musical voice, and a national stock of high animal spirits, he was the delight of all festive assemblies, taking his pleasure freely, but never to excess. . . .

"On the Restoration, Valentine Greatrakes lost his offices, and was reduced to the position of a mere private gentleman. His estate at Affane was a small one, but he laboured in it with good results. . . . Perhaps he missed the excitement of public business, and his energies, deprived of the vent they had for many years enjoyed, preyed on his sensitive nature. Anyhow, he became the victim of his imagination, which, acting on a mind that had been educated in a school of spiritual earnestness and superstitious introspection, led him into a series of remarkable hallucinations. He first had fits of pensiveness and dejection, similar to those which tormented Cromwell ere his genius found for itself a more fit field for display than the management of a brewery and a few acres of marsh land. Ere long he had an impulse, or a strange persuasion in his own mind (of which he was not able to give any rational account to another), which did very frequently suggest to him that there was bestowed on him the gift of curing the King's Evil, which, for the extraordinariness of it, he thought fit to conceal for some time, but at length communicated to his wife and told her 'That he did verily believe that God had given him the blessing of curing the King's Evil, for whether he were in private or in publick, sleeping or waking, still he had the same impulse; but her reply was to him, that she conceived this was a strange imagination.' Such is his statement. . . .

"Patients either afflicted with King's Evil, or presumed to be so, were in due course brought before him; and, on his touching them, they recovered. It may be here remarked that in the days when the Royal Touch was believed in as a cure for scrofula, the distinctions between strumous and other swellings were by no means ascertained even by physicians of repute; and numbers of those who underwent the manipulation of Anointed Rulers were suffering only from aggravated boils and common festering sores, from which, as a matter of course, nature would in the space of a few weeks have relieved them. Doubtless many of Valentine's patients were suffering, not under scrofulous affections, but comparatively innocent tumours, for his cures were rapid, complete, and numerous. . . .

"Greatrakes himself also speaks of his more violent curative exertions making him very hot. But it was only occasionally that he had to labour so vehemently. His eye, the glance of which had a fascinating effect on people of a nervous organisation, and his fantastic ticklings, usually produced all the results required by his mode of treatment. . . .

"The fame of the healer spread far and wide. Not only from the most secluded parts of Ireland, but from civilised England, the lame and blind, the deaf, dumb, and diseased, made pilgrimage to the Squire of Affane. His stable, barn, and malt-house were crowded with wretches imploring his aid. The demands upon his time were so very many and great, that he set apart three days in the week for the reception of his patients; and on these days from six in the morning till six in the evening, he ministered to his wretched clients. He took no fee but gratitude on the part of those he benefited, and a cheering sense that he was fulfilling the commands of the founder of his religion. The Dean of Lismore cited him to appear before the ecclesiastical court, and render an account of his proceedings. He went, and on being asked if he had worked any cures

replied to the Court that they might come to his house and see. The judge asked if he had a licence to practise from the Ordinary of the Diocese; and he replied that he knew of no law which prohibited any man from doing what good he could to others. He was, however, commanded by the Court not to lay his hands again on the sick, until he had obtained the Ordinary's licence to do so. He obeyed for two days only, and went on again more earnestly than ever."

Under the encouragement of high patronage Greatrakes migrated to England, where he rapidly became a star of the first magnitude. "Lord Arlington commanded him to appear at Whitehall, and perform in his peculiar fashion for the amusement of His Majesty Charles II.

But the majority of his admirers were ladies; the Countess of Devonshire entertained him in her palace; and Lady Ranelagh frequently amused the guests at her routs with Mr. Valentine Greatrakes, who in the character of the lion of the season, performed with wondrous results on the prettiest or most hysterical of the ladies present. It was held as certain by his intimate friends that the curative property which came from him was a subtle aura, effulgent, and of an exquisitely sweet smell, that could only be termed the divine breath." Dr. Henry Stubbe, a famous physician who practiced in Stratford-upon-Avon, informs his readers that "God had bestowed on Mr. Greaterick a peculiar temperament, or composed his body of some particular ferments, the effluvia whereof, being introduced sometimes by a light, sometimes by a violent friction, should restore the temperament of the debilitated parts, re-invigorate the blood, and dissipate all heterogeneous ferments out of the bodies of the diseased by the eyes, nose, mouth, hands, and feet. I place the gift of healing in the temperament or composition of his body, because I see it is necessary that he touch them. Besides, the Right Honourable the Lord Conway observed one morning, as he came into his Lordship's chamber, a smell strangely pleasant, as if it had been of sundry flowers; and demanding of his man what sweet water he had brought into the room, he answered, None; whereupon his Lordship smelled upon the hand of Mr. Greaterick, and found the fragrancy to issue thence; and examining his bosom, he found the like scent there also." Dean Rust gave corresponding testimony, and "Sir Amos Meredith, who had been Mr. Greaterick's bed fellow," also testified to the same effect.

The Anglican career of our fellow-countryman was, however, not a prolonged one. His outshining brilliancy naturally made him hosts of enemies: slander became too active; he was accused of profligacy and blasphemy, and what other vices his enemies thought would prove most damaging to his position in the public estimation. The tide of slander proved in this case irresistible, and Greatrakes retired before it to seek repose in his native country. It is not a little remarkable, however, that he succeeded in securing the confidence and patronage of the illustrious scientist Boyle, and of the famous theologians Wilkins, Patrick, and Cudworth. In his "Memoirs of Remarkable Persons," Caulfield gives a portrait of V. Greatrakes, Esq., stroking a patient, and tells us that "Mr. Glanville imputed his cures to a sanative quality inherent in his constitution, some to friction, and others to the force of imagination in his patients." He further observes that "His manner of stroking some women was said to be very different from his usual method of operation."

In a foot-note, on the same page, we are informed that "In the reign of Charles I. an accusation was brought before the Court of Star Chamber, and afterwards before the College of Physicians, against one John Leverett, a gardener, who undertook to cure all diseases, but especially the King's evil, "by way of touching or stroking with the hand." He used to speak with great contempt of the royal touch, and grossly imposed upon numbers of credulous people. He asserted that he was the seventh son of a seventh son; and profanely said, that "he found virtue go out of him," so that he was more weakened by touching thirty or forty in a day, than if he had dug eight rods of ground. He also affirmed, that if he touched a woman, he was much more weakened than if he had touched a

man. He was by the censor of the College adjudged an impostor."

Both these methods of treating the King's Evil were recognised and practised among the peasantry of the West of Ireland. The direct application of the Royal Touch was, of course, out of the question. But a "knowledgeable" elderly woman possessed some of the "Royal blood and remains"—something mysteriously wrapped up in a linen rag, with which the "Evil" was touched three times, "with certain prayers." The ceremony was performed on Mondays and Thursdays only; and no intervening Monday and Thursday could be allowed to elapse till the number of applications had been completed.

The Seventh son's touch was applied on corresponding days, and with similar ceremony. It was usually efficacious; absolutely so, if the operator happened to be the seventh son of a seventh son; as in the case of Leverett, just cited. As the touch of the mere seventh son was not always infallible, it was considered desirable to test it immediately after birth, by filling the hand of the new-born infant with healthy earth-worms. If a born healer, as such a boy usually was, the earth-worms at once ceased to live.

The only herbal cure I ever heard of being used in the West was that described at the opening of this paper.

I have now brought to a close my prolonged history of the blind struggle of the unenlightened past centuries with the non-exorcisable demon of the King's Evil. I feel that an apology—perhaps I should have said a great many—is due to my readers for inflicting upon their attention so very lengthy a catalogue of now forgotten or unrecognisable "remedies." Still I must take the liberty of suggesting that a cursory glance at the same can never prove uninteresting to the true lover of our profession, who may not lose sight of its past any more than of its present; nor un-instructive to the philosophic student of human nature, who tries in all directions for the chinks and loopholes through which light has at length penetrated into its arcana; nor ungratifying to the philanthropist, who examines with pleasure the sure, though often very slow, stages by which means of relief have been discovered for the otherwise hopeless physical ills to which we all are born heirs. And if the smart, up-to-date, self-satisfied scientist feel disposed to turn away with contempt from the contemplation of the rubbish-heap of old-time "cures" and historical items of superstitious faith-healing which I have scraped together for his holiday edification,—I would gently whisper in his ear that even in this last year of our progressive nineteenth century, the treatment of scrofulous disease still lies a long way on the human side of perfection, and that his supercilious self-congratulation in looking over the extracts from my scrap-book will probably be fully paralleled in the outlines of thought of the advanced "professor" of the closing months of the year 1999, while glancing backwards at the history of the creed of the bacteriological pathologist of to-day, with its characteristic outgrowths of tuberculin and antitoxin.

The Nursing Problem.

NURSES OF THE LATEST FASHION.
A.D. 1899.

PROFESSIONAL EXPERIENCES IN SHORT
STORIES.

By FREDERICK JAMES GANT, F.R.C.S.,
Consulting Surgeon to the Royal Free Hospital.

III.—THE DOCTOR-NURSE.

SINCE the days of Mrs. Gamp—say, half a century ago—the progressive development of the modern nurse has culminated in the nurse up-to-date; eclipsing the personality of the great, great-grandmother, or rather burying her as an extinct species in ground which can never be opened again to view her remains, unless by express per-

mission of the Home Secretary under an Act of Parliament for the purpose. There she lies, whatever there is of the short, fat, florid-faced woman, of kindly disposition, but stupid, ignorant, negligent, muddled even more by perpetual drops of gin or brandy from the bottle she concealed in her pocket, and stealthily carried to the lips of its owner. Her dress is loose and slovenly, not too cleanly, certainly not "antiseptic." She sat thus asleep, awake, at fitful intervals, to administer the doctor's stuff, in constant attendance, never taking her clothes off for days and nights together, and never washing herself, if she damp-towelled and brushed up her sick charge—man, woman, or child. As death approached the sufferer, the old-fashioned nurse could not see her patient through her bleared eyes—still watching; and when the departed spirit had flitted from its tenement as a bird escapes from a broken cage, nurse, or the "spirits" within her fat little body, could hardly tell when the man with the scythe had called, and the flesh as grass was mown down. She believed that sometime in the early morn he usually did his work, and as the death-dew had moistened the grass at 4.17 a.m., she was positively certain that at that hour and minute precisely, a corpse lay before her. Besides, to make doubly sure, old nurse asked her unerring witness—the breath steam or its absence, on a piece of glass held near the mouth of the body, living or dead, and whether the jaw has dropped. But "I always feels their legs," which soon stiffen.

Then she proceeds to close the eye-lids, to cover the dull, fixed eyes, lest they should see her mauling grief; and she ties up the jaw lest the tongue should thank her for her night-vigils, while the spirit of the departed yet lingered on the threshold of the unseen, coming back and receding, with fitful renewals, and retrogressions of life. Now that death has doubtless gotten the victory in this world, nurse "lays out" and "washes" the corpse, and renders other services of decency, than dressing and decorating the body ere it lies in its last bed. She declares that soon the wonted smile has returned, with a freshness of colour in exchange for the ashy hue, the face "looks beautiful." And then—then, old nurse revives herself from her bottle, looking only less beautiful. Exit.

My portfolio includes Blanche, the modern and model nurse. Look on her picture, and that of her great, great grandmother. But the two contrast more than in personal appearance, dress, and character. The education of to-day has reached the modern representatives of nursing-women. The "schoolmaster is abroad"—a saying of Lord Brougham, who did so much to popularise higher education—has knocked at the door, and been admitted into hospital training schools; and in the person of some specially appointed member of the Medical and Surgical Staff regular courses of lectures, and practical instruction, are given to nurses. They are not left to discover for themselves what should be their course of training in the wards, and are taught very much more, in the knowledge of elementary anatomy, physiology, and practical work with relation to the treatment of diseases and injuries.

Whether or not the nurse up-to-date is thus *overtaught* does not enter into the purpose of this essay to discuss. A corresponding order of examinations concludes the nurse's curriculum ere she can obtain her "certificate" of qualification. The outcome of all this advanced education has produced its fruit; ripe and good nurses, unripe and bad—as with regard to their technical education and knowledge. But, while possessing far greater fitness for the duties of a trained nurse, other personal qualifications being equal, our nurse of the newest pattern is apt to assume the impersonation of the doctor, under whose directions she is mostly in service.

I was perhaps the first member of my profession to pronounce the name "profession"—in the former now defunct "Association of British Nurses." The title, professional nurse, has now grown familiar. But the two professions, that of physician, surgeon, medical practitioner, and that of nurse or sister, cannot possibly be identical; although both doctor and nurse necessarily meet on common ground in their attendance on the sick for the mutual benefit of the patient, and with the happiest relation between themselves, so long as

they both fulfil their respective functions never to be confounded.

The public generally fall readily into error, grievous to the patient's welfare. Both doctor and nurse often act together in the same cases; and their distinctive professions, certainly their relative duties and special merits, may seem to be a distinction without any essential difference. Nay, the public may, perchance, have no affection for the doctor's compared with the nurse's merits; and then the husband, wife, son, or daughter, would reverse the famous definition, more witty than wise:—"The doctor is a man (or nowadays, a woman) who pours medicine, of which he (or she) knows little, into a body of which he knows less;" but that "the Nurse pours medicine, of which she knows much, into a body of which she knows more!"

Given, therefore, a fully trained nurse, "such a clever Nurse," in attendance with the doctor; the one also presenting a more winning personality than the other member of the same profession, as they seem to be in the eyes of a patient, the relatives and friends; which of these two will gain most, the confidence and the gratitude of the public?

Assuming even more on behalf of the nurse; she, with her qualifications and personal qualities—is self-assertive, and talks largely of her experience, and of how little she thinks of some doctors—young perhaps in their profession and of small practice; the doctor-nurse quite eclipses the doctor.

To fill in the picture with more touches of detail.

Nurse arrives in attendance on a case. She enters the sick room; an old feeble-minded husband is lying in bed; an anxious, nervously excitable wife is watching by his side. "So thankful, Nurse, you have come; doctor said he would send you: although (aside) he assures me there is no danger." Nurse approaches the bed with an engaging smile; she places her two fingers on the pulse and withdraws from her waistband a small watch. The old husband looks up at her with a puzzled expression, the wife eyes her attentively. Suddenly, nurse's visage drops to zero as she interprets the language of the pulse with almost momentary decision. "Here we have a bad case." The old man closes his eyes in hopeless despair as of one doomed to death in the prisoner's box; his wife's face bespeaks the utterable, as she hears nurse's verdict.

But, no. Nurse yet hopes (D.V.) to "pull the patient through," despite the bad case; and she has shrewdly not pronounced a hopeless prognosis. The patient *does* recover, and certainly, while in nurse's hands, the doctor paying his visits, prescribing, and giving directions, which may or may not be fully carried out. Has not nurse fully justified her superior professional claims? and does not her self-assertiveness entitle her to the appellation, "Doctor-Nurse"?

In surgical cases, more especially, a self-assertive nurse may more readily pass for a surgeon; and in these days, when properly authorised women-doctors may practise surgery.

The training of a nurse rightly includes some knowledge of surgical apparatus employed in the treatment of numerous surgical cases; and she possesses, therefore, a nurse-knowledge of mechanical appliances in cases involving their use. But her training does not comprise the prior detection, the diagnosis of the kind of injury or local disease; pathological knowledge which is needed for the efficient use of the mechanical appliances. So again, in the performance of surgical operations, her knowledge of the instruments used—enabling her to assist in some cases—does not enable her to follow the operator, whose hands are methodically at work, deeper, and yet deeper in the anatomical structure of the body, while death may hover around the point of his knife.

In either respect, the knowledge of a thoroughly qualified nurse is simply mechanical; and any further knowledge—as of the structure, functions, and altered conditions of the parts—from injury or disease, does not concern her, might, indeed, be positively mischievous in most cases, but pertains to the surgeon, who is alone responsible. Nurse cannot lawfully practise surgery; she has not undergone any examination—for that purpose; and she does not hold any diploma, or degree, in

surgery, of any College of Surgeons, or of any University.

In their rightly understood relationship, the surgeon fully appreciates nurse's co-operation with him, and thankfully acknowledges her services. The patient, relatives and friends, cannot rightly estimate the one, and will overestimate the other. The popular conception is hazy and confused; and in the eyes of many people, the nurse handing the instruments and the surgeon using them, are too intimately associated together, to be practically distinguished. The surgeon might be more readily transferred into the nurse, than the nurse seem to be discredited as a surgeon. Their identification would have been once a paradox; but now the time gives it proof! Of course, I speak not of hospital practice, but of private cases, and of some nurses only, as representatives of "the newest pattern."

In the medical, as distinguished from the surgical, treatment of disease, there are "doctor nurses," not a few. They figure, sometimes, in the daily papers, as medical authorities; granting certificates as testimonials, recommending the beneficial effects of various medicines and articles of diet for the sick. These nurses are quite of the latest fashion. Here is one such doctor-nurse, of many others, whose testimonial of Byrrh, as a tonic wine, I read in the *Sunday Times*, March 19th, 1899:—

Nurse Marina Steene, R.B.N.A.,

Home Villa, 22, North Bank, N.W.

"As an invigorating and restorative tonic, I must say Byrrh is far superior to any wine I have tried both for 'patients' and for myself." The obvious inference from this testimonial would be that "Nurse Steene" has patients of her own, under her treatment, as well as doctoring herself, a case in which probably by a mistaken professional opinion, she could do no harm to anybody.

There is yet another nurse of the same species, be they many or few, whose self-assertiveness assumes another form. She affects to be a great authority on all sanitary arrangements, turning the house round, and ordering all its inmates in subjection to her special knowledge of hygiene. Beginning with the sick room: "I must have all this altered or I cannot stay here." She is a radical sanitary reformer. The same spirit of absolute authority extends to the household service under her sway. The husband, who may be very "much married," now finds in nurse a new mistress of himself, and of his servants in their respective offices, whether male or female domestics. Everybody nurse would order and control, as subservient to the proper management of the sick room, and of the patient "who is under my care." But why follow any further the footsteps all over the house of this irrepressible untameable shrew.

The doctor-nurse figures mostly—for an obvious reason—when she is in attendance alone, as in cases of chronic invalid patients. Her self-assertiveness to be what she is not may simply express an unbecoming character only. But she appears in quite another light when the same character is that rather of an impostor upon the credulity of a public ever credulous in nurse-land.

Transactions of Societies.

BRITISH LARYNGOLOGICAL, RHINOLOGICAL,
AND OTOLOGICAL SOCIETY.

MEETING HELD FRIDAY, JULY 28TH, 1899.

J. DUNDAS GRANT, M.D., in the chair.

The following gentlemen were elected officers for the ensuing year, 1899-1900:—President, Dr. Barclay Baron (Bristol); Vice-presidents, Dr. Percy Jakins, Mr. John Bark (Liverpool), Mr. Wyatt Wingrave; Council, Dr. Middlemass Hunt (*ex officio*) (Metropolitan), Dr. Furniss Potter, Mr. Dennis Vinrace, Dr. Greville Macdonald, Dr. Abercrombie (Extra Metropolitan), Dr. Tresilian (Enfield), Dr. J. D. Hillis (Dublin); Treasurer, Dr. Dundas Grant; Hon. Secretaries, Mr. St. George Reid, Dr. Cichele Nourse.

The following cases and microscopical sections were shown:—

OTOLOGY.

Dr. DUNDAS GRANT: Case of pyæmia from thrombophlebitis of the lateral sinus, subsequent to chronic suppurative inflammation of the middle ear, treated by evacuation of the sinus and ligature of the internal jugular vein with recovery.

Dr. FURNISS POTTER: Case of extreme thinning of tympanic membrane in which there had been no symptoms indicating ear mischief until about six weeks previously.

MICROSCOPICAL SECTIONS.

Dr. FURNISS POTTER: Columnar epithelioma of maxillary antrum.

MR. WYATT WINGRAVE: Squamous papilloma of larynx.

LARYNGOLOGY.

Mr. WYATT WINGRAVE: (1) Case of laryngeal papilloma in a little girl at 7 years. The warts were situated at the anterior commissure, and were removed by Krause's endolaryngeal snare, but had twice recurred at intervals of one month. There were no "adenoids." (2) Case of keratosis of the faucial and lingual tonsils, which having resisted treatment by chromic acid, galvanic cautery, &c., for twelve months, had yielded to the weekly applications of a saturated solution of salicylic acid in rectified spirit.

Dr. DUNDAS GRANT described a case of primary syphilis of the lip.

Dr. FURNISS POTTER: (1) Case of recurring singer's nodule; (2) case of recovery of motor power in a case of complete recurrent paralysis of left vocal cord, together with marked paresis of left side of soft palate, and same side of tongue. (Shown at the Laryngological Society of London, last February.) The patient was a man, æt. 48, who stated he had a "sore" twenty years ago, but no rash, sore throat, or other sign of constitutional infection. When first seen in January of this year the left cord was observed to be incapable of any abductor movement, and a month later the paralysis became complete; the cord assuming the cadaveric position. The left side of the soft palate was markedly paretic with some diminution of sensation, chiefly along the lower border, and the tongue, when protruded, deviated to the left side. No affection of trapezius, sterno-mastoid or orbicularis oris. Examination of chest gave a negative result. He had taken iodide for nearly six months, and now had entirely recovered motor power. The left cord moved freely, the action of the soft palate was not impaired, and the tongue could be protruded without any lateral deviation.

France.

[FROM OUR OWN CORRESPONDENT.]

PARIS, August 13th, 1899.

EARLY DIAGNOSIS OF PHTHISIS.

PROFESSOR GRASSET, of Montpellier, read a paper at the Medical Congress on the early diagnosis of pulmonary consumption by the employment of small doses of tuberculine. He made the experiment on 28 cases, 14 of which did not present any reaction, while in the remainder the reaction was positive. In three cases of advanced phthisis, where the lesions were well marked, reaction failed completely. The Professor concluded by saying that the injection of tuberculin afforded an excellent means of detecting tuberculosis in man on the condition that infinitesimal doses were employed, that no fever were pre-ent and that the lesions were not too advanced. The reaction could only be considered positive where the temperature exceeded one degree at least. That rise in the temperature was only apparent twelve hours after the injection and lasted forty-eight hours.

M. Combemale said that in about thirty cases he had tried to establish the early diagnosis of tuberculosis by injections of artificial serum or with serum and tuberculin alternately. The febrile reaction provoked by the saline injections did not constitute an absolute proof of the existence of tuberculosis in certain subjects, for the reaction was found in persons that were not tuberculous, consequently injections of artificial serum were far from constituting a practical means of making an early diagnosis of pulmonary consumption.

M. Clinquet, of Cannes, made some interesting experiments on the temperature of suspected consumptives. He recommended the patient to take a walk between three and four o'clock each day, and took his temperature immediately afterwards, and again when he had rested an hour. This experiment was repeated daily for ten days. Where the difference in the temperature was half a degree, and if the temperature of four o'clock was higher the days the patient took the exercise it might be affirmed that the individual was tuberculous.

In woman another presumptive sign consisted in the rise of the temperature of from four to ten-tenths of a degree one or two days before the menstrual period.

M. Rondot read a paper in which he tried to show that the first signs of pulmonary tuberculosis showed themselves in the hilus of the lung before any sign could be detected in the apex. That tuberculosis of the region of the hilus revealed itself by large rales which subsisted for a long time, and became exaggerated after injections of tuberculin, or the administration of iodide of potassium.

EXOPTHALMIC GOITRE.

The treatment of exophthalmic goitre has rarely given satisfaction. Injections of tincture of iodine into the body of the gland, which gave excellent results in simple goitre, produced frequently abscesses in the thyroid body. Prof. Pitres, of Bordeaux, has tried injections of a solution of iodoform and ether (one per cent.), repeated every eight days, with encouraging effects. The injection was generally painful, but varied with the degree of sensitiveness of the subject. A short time after the final injections the nervousness ceased, the sleep returned, the gland diminished in volume, and the exophthalmos disappeared. The improvement was well marked after the third injection; however, it was necessary to continue them for several months in order to render impossible a return of the malady. M. Pitres treated thus a dozen patients, but some of them he was not able to follow up, as they ceased the treatment as soon as they had improved enough to return to work. However, he says he can count six definite cures. In some cases over 100 injections into the gland were made without witnessing any accident, but he wishes to notice a phenomenon, which is sometimes produced in the course of the injections, and which might, at first sight, give rise to some uneasiness; it consisted in a kind of bubbling like that observed in the case of introduction of air into the veins.

H.R.H. PRINCESS HENRY OF BATTENBERG opened on Thursday last, on behalf of her Majesty, a new block of the Royal National Hospital for Consumption and Diseases of the Chest, the foundation-stone of which was laid by the Princess two years ago.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, August 11th, 1899.

At the Free Society of Surgeons Hr. Neuman reported on the cases of

IMPALING

that had been treated at the Friedrichshain Hospital from 1880. Out of 20,000 accident cases during that period only 16 cases were of impaling, and out of these the injuries were to the head in 4 and to the trunk in 16. Injury to the face with its numerous projections that prevent glancing off is more likely than over the smoother part of the skull, and as a matter of fact all the cases were those of injury to the face. A splinter of wood entered the right orbit, injured the ball, penetrated through the antrum of Highmore into the mouth. After enucleation of the ball a portion of the foreign body was removed through the orbit, the remainder being extracted from below. The wound was drained, and recovery took place. In the second case the spout of an oil can was driven into the orbit and from there into the orbital fissure. Orbital phlegmon followed, accompanied by symptoms of meningitis, but recovery took place after free opening up.

In a third case the handle of a paint brush penetrated through the upper lip through the antrum of Highmore into the orbit. Recovery.

The fourth case was one of so-called trumpet injury. Whilst the patient was blowing a whistle, this was driven in by a blow on the mouth, and it passed through the palate into the nasal cavity and up to the base of the brain. Recovery took place.

Of impalings of the trunk, those in front were dealt with first, the severity of the injury being dependent on the force with which the instrument was driven in, the character of the foreign body, whether this had a pointed or blunt end, and the part of the trunk injured. Impalings of the perineum did not generally lead to opening of the peritoneum, they were generally extra-peritoneal. The worst case reported was one in which a stick penetrated from the perineum to the axilla, the whole track of the wound was extra-peritoneal. The four cases of this class all recovered. In another case the injury was caused by a fall from a window upon iron spikes one of which penetrated the hip-joint. Here death took place from pyæmia.

In one case the foreign body passed through the lesser ischiadic foramen, and through the rectum in three cases.

In those cases in which the peritoneum was opened, some one of the solid abdominal organs was generally injured at the same time. The stomach and intestines might be torn or perforated, or the bruising they underwent might lead to necrosis.

THE WEISS METHOD OF TREATMENT OF THE URIC ACID DIATHESIS.

Dr. J. Weiss, of Bâle, gives an account of his so-called new method of treating the uric acid diathesis in the *Berl. Klin. Woch.*, 14 99. The author found that a diminution of the excretion of uric acid was brought about by the use of fruits. He tested the activity of the individual parts, but obtained only a negative result. On the other hand, on giving chinic acid he found a distinct diminution of the uric acid. Whatever the action

might be, it deserved to be used, as it was the only remedy against the uric acid diathesis that had no ill effects. Quinine diminished the formation of uric acid, but it was not a remedy that could be given in large doses, and for long periods a combination of chinic acid with lithium was the most appropriate. Although lithia had no influence on the formation of uric acid, on account of its diuretic action its value should not be under estimated. As on account of the taste and want of solubility it was best not to give the acid by itself, but as a salt he preferred the lithia to the soda base.

At the Hufeland Society Hr. Jacob read a note on

THE TREATMENT OF TETANUS.

He said that at the Congress of Medicine last year, at Wiesbaden, he had spoken on a method that had the object of increasing the therapeutical value of Quincke's lumbar puncture. This method that he had called "dural infusion," had been tried in a number of suitable cases in Leyden's klinik, and to some extent surprisingly favourable results had been obtained. The procedure had been further tested experimentally, especially from the point of view of endeavouring to obtain better results in tetanus than by the simple injection of the serum. In association with Blumenthal, he had experimented on goats, injecting a certain quantity of tetanus toxin, and then endeavouring to save the animal by simple or sub-dural injection of the curative serum. He did not succeed, however, by either method. After a few days the animal invariably died from the tetanus, the antitoxin not having the power of staving off for even a few hours. He was able to ascertain that the tetanus antitoxin was very active, but it was not able to remove the poison that was already located and fixed in the central nervous system. Then experiments were made on immunity, and it was found that animals first injected with tetanus toxin and afterwards with tetanic antitoxin in the same way generally remained well, and it was the same with animals who had first dural infusion of tetanus antitoxin and later on tetanus toxin. But, on the other hand, those animals died of tetanus who were first given tetanus antitoxin subcutaneously, and some hours later tetanus toxin under the arachnoid. Inter-cerebral injections were then tried in animals in which the disease had already developed, but they were without any result.

Reckoning up all that was known on the subject, the author concluded that at present there was no method known of expelling the tetanous toxin out of the cerebral system when it was once chemically combined and anchored there. The injection or dural infusion could therefore only have the effect of neutralising the tetanus toxin circulating outside the central nervous system, and thereby preventing any further chemical combination taking place in the brain.

INFILTRATION ANÆSTHESIA.

This method of inducing anæsthesia seems much more cultivated in Germany than in other countries, and a recent article by H. Braun in *Volkmann's Archiv.* brings it still further to the front.

The best medium for producing the anæsthesia is the eucaïne B solution (eucaïne B 0.1, sod. chlorid 0.8, aq. dist. 100.0). This solution admits of sterilisation, whilst cocaine does not. Before the operation Braun always gives a morphia injection, but not in the region to be

operated on. The method of injection is that adopted by Schleich himself. He has performed both minor and major operations under this form of infiltration anæsthesia—tracheotomies, empyo-thoracentesis, abdominal sections (20 cases). The solution is said to be very suitable for hydrocele operations. After removal of the fluid, the sac is filled tensely full with the fluid, and in a quarter of an hour the tissue to be removed is infiltrated with the solution. The regionary anæsthesia recommended by Oberst is most suitable for phlegmons and diffuse inflammations.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, August 12th, 1899.

LOCAL ANÆSTHESIA IN MAJOR OPERATIONS OF THE EXTREMITIES.

BERNDT recommends an operation which he practises with cocain and common salt for local anæsthesia in operations of the extremities. After applying an Esmarch bandage, a solution of 4 to 5 centigrammes of cocain in 40 to 60 cubic centimetres of a "physiological salt solution" is injected into the neighbourhood of a large nerve trunk. After injecting, the operator requires to wait twenty to thirty minutes before anæsthesia is complete.

ANGINA AND ACUTE ARTICULAR RHEUMATISM.

Some time ago Sanger expressed the opinion that articular rheumatism was nothing but a low form of pyæmia, and gave a few cases in proof of this contention. Kronenberg adds another of these to our literature, with a post-mortem that certainly gives some colour to the original hypothesis. Having occasion to operate on the concha of one ear of the patient, the throat of the same side became affected, which, with a little treatment, subsided in a few days. Later the nostril of the opposite side of the head was operated on with a similar result on the same side of the throat as the operation, but this time did not clear off as quickly as the opposite side of the throat after the ear operation, but, on the contrary, was rapidly followed by an attack of acute articular rheumatism, with its various complications, endocarditis, pericarditis, pleuritis, pneumonia, and death. The articular rheumatism in this case had every appearance of a pyæmic origin.

ICTERUS NEONATORUM.

We have had a large number of hypotheses on this subject, but none so original in these days of hygiene and preservation as that propounded by Schonewald, who persistently maintains in opposition to Gessner's philosophy, that icterus in early life is due to the imperfect cleansing of the infants' skin before dressing, which is frequently done without due care! He allowed 67.5 per cent. of his cases to be washed in the usual way, and all of them had icterus more or less, while the other 32.5 were free from icterus, being cleansed according to his own preservative method.

HÆMOPHILIA.

Gocht at the meeting of Physical Medicine drew attention to the bleeding into the joints, and demonstrated his remarks with three cases under treatment. Hæmophilia

he said, was a congenital condition that usually manifested itself most prominently in the child about the period of walking. It may be stated without exception that the slightest injury will produce hæmorrhages into the joint, particularly the knee-joint. This disposition to inter-articular bleeding depends on several causes: for example, period of life. Repeated hæmorrhages cause a change in the anatomical condition of the joint, and by this means future hæmorrhages are usually prevented.

The diagnosis of these cases is always a difficult task, which must be conducted by König's test, and which is entirely symptomatic, while the post-mortem reveals the pathological changes.

He then showed two brothers with similar histories whose families had the same trouble. One of the boys brought forward was remarkable from the number of times the hæmorrhage had recurred, being 45 times in the right knee, 11 times in the right foot, seven of which were very severe, and had to be bandaged. The facts of these cases confirmed Grandidier's assertions that the disease is notoriously hereditary.

The treatment might be characterised as prophylactic. In a recent effusion absolute rest must be rigidly adhered to, while warm compresses, or ice may be applied with advantage, but in all treatment the central vital force must be well sustained. Subsequent muscular exercise with electricity and massage may be found to be of great service.

Repeated effusion and sluggish absorption may ultimately produce contractions and deformity requiring orthopædic interference. Puncture of the joint should be carefully avoided, as well as "Revirement." If the limb requires an appliance to be worn, the apparatus should be light and fit neatly.

TROPON.

Neumann gave the meeting a history of the experiments conducted on himself with this food (tropon). Three conditions were necessary in all nutrient food stuffs: (a) it should be easily absorbed; (b) when given in large quantities it should not upset the stomach; (c) it should be palatable to the taste; and, lastly, it should not be too dear. All artificial preparations containing albumen transgressed the last canon.

The latest on the market were somatose, nutrose, and eucasin, which were more or less defective in peptones, and dear, and were, he considered, inferior to tropon. This nutrient is a dry brown powder, insoluble in water, and without any characteristic smell, while the taste reminds one of bean meal. It contains one-third of animal and two-thirds of vegetable albumen.

The Operating Theatres.

MIDDLESEX HOSPITAL.

LAPAROTOMY FOR REMOVAL OF A SOLID OVARIAN TUMOUR.—Mr. JOHN MURRAY operated on a woman, æt. 60, who three years before had been operated on for removal of an ovarian tumour on the left side. She had continued well till six months previous to admission, when she noticed a swelling in the lower part of the abdomen, which gradually increased until a month before admission, since when the swelling had very

rapidly increased in size. On examination the abdomen was found to be greatly enlarged, this was evidently caused by a large accumulation of fluid in the peritoneal cavity. At the lower part the abdomen felt more resistant, which suggested the probability of the existence of a tumour. On vaginal examination the uterus was movable, and an indistinct swelling could be felt in the posterior fornix. The abdomen was opened in the middle line below the umbilicus and a large quantity of ascitic fluid escaped. A tumour was found filling up the entire pelvis, firmly adherent all over except anteriorly. The incision had to be enlarged above the umbilicus. The adhesions were then carefully separated and numerous ligatures applied. Two coils of intestine were adherent to the tumour; in separating one of these the wall of the intestine was partially torn; the tear was at once closed by Lembert's sutures. The other coil was so firmly attached that a portion of the tumour had to be left adherent to the intestine. All other adhesions having been separated, the tumour was removed. It was found to be for the most part solid, and probably malignant in nature; it measured about nine inches by six. A number of bleeding points had to be tied at the site of the peritoneal adhesions, and the oozing, which was still persistent, was arrested by the application of hot sponges. The wound was closed, and a glass drain tube inserted into the pelvis. The patient was very collapsed after the operation, and an enema containing 3ss of brandy was administered. Mr. Murray said that the operation was undertaken for the purpose of exploration. Arguing from the history it was probable that there was a simple ovarian tumour which might easily be removed; on the other hand the presence of ascites suggested the possibility that the growth was not only malignant but diffused. He thought there could be little doubt as to the malignant nature of the growth. In the first place, the manner in which it involved part of the intestine, pointed strongly to malignancy, and in addition there were noticeable at the operation several small whitish subperitoneal spots on the intestine, which he considered strengthened this opinion. Nevertheless, he thought the removal of the tumour was desirable, partly because its nature could not be definitely known until the microscopical examination, and also because, owing to the rapid increase in size and the manner in which it was impacted in the pelvis, its presence would very shortly have given rise to severe pressure signs. With regard to the introduction of the drain tube, on account of the amount of oozing that was taking place, he considered it advisable to drain the pelvis. If all went well the tube would be removed in twenty-four hours.

It is satisfactory to state that at the end of a week there has been no rise of temperature; the tube was removed the day after the operation, and the progress of the case so far is satisfactory.

WEST LONDON HOSPITAL.

RUPTURE OF EXTRA-UTERINE GESTATION.—Mr. BIDWELL operated on a woman, æt. 26, whose youngest child was 6 years of age. Since then her periods had been regular till two months previous to admission, when signs of pregnancy had developed. Four days before admission she had complained of severe pain in the right iliac region, and had passed a small amount of

blood per vaginam. The abdomen became distended and signs of peritonitis developed. The general swelling subsided and a mass formed in the right iliac fossa. On vaginal examination the uterus was found to be slightly enlarged and pushed to the left side, and a mass could be felt in the posterior wall of the vagina, which was continuous with the mass in the right iliac fossa. The abdomen was opened in the right linea semilunaris and a quantity of blood was found free in the peritoneal cavity. This was washed away, and after removal of a quantity of blood clots in Douglas's pouch, the right Fallopian tube was found to be ruptured, and had evidently been the site of a pregnancy. The tube was removed together with the right ovary; the abdomen was flushed out with normal saline solution to remove blood clots, and closed in the ordinary way. Mr. Bidwell said the case was interesting, as the physical signs would rather have pointed to an attack of appendicitis than to tube-pregnancy, but the history made the latter the more probable. He thought it always indicated to open the abdomen when there is any suspicion of a ruptured tubal pregnancy, since if it is left and the placenta formed, this last will become adherent to the intestines, and make a late operation very difficult and dangerous. He referred to a case he had operated on at the tenth month, the child had died and the placental membranes were in a very sodden state, the result being that in peeling them off part of the swelling of the intestine was ruptured. The patient, however, made an excellent recovery, after excision of several inches of the involved intestine. He admitted it was not impossible in some cases of ruptured tubal pregnancy for the blood and ovum to become absorbed, but even in these cases the convalescence would be more tedious than after operation. The reason, he pointed out, for making the incision in the linea semilunaris instead of in the middle line was an account of the possibility of the vermiform appendix being involved. He asserted that it was no more difficult to remove the uterine appendages through an incision in the linea semilunaris than through one in the middle line.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, AUGUST 16, 1899.

THE ALLEGED INCREASE OF LUNACY IN IRELAND.—I.

OUR contention is—and we shall develop the supporting argument as we proceed—that if insanity

is to be considered as a distinctive and curable disease of the human mind, calling for treatment in special hospitals, a continuous series of scientific efforts should be made to ascertain its genuine varieties to the exclusion of all doubtful and spurious cases. As we write we have before us the Fifty-Third Report of the English Lunacy Commissioners just published. Its bulk is as usual proportionate to the area it covers, and about one-third the size of what its Irish fellow probably will be following the good old conventional and unprogressive lines common to both, for years. We presume the latter will soon be in our hands, as the date of its usual appearance ("old style") is approaching. We can only say now that the English report opens with the statement, that the lunacy population of England and Wales, during the year was ascertained to be 105,086, including 6,000 "out-door paupers." The report, occupying sixty-two pages, is signed by Lord Waldegrave the new chairman—the remaining 400 pages—being the usual statistics and inspections, which few will care to venture on now that there is no Charles Reade to present them in sensational aspects. We have also at present before us a printed report that there are now on the books of the Richmond Asylum 2,127 patients—that Portrane at present accommodates 400 male patients, and the Grangegorman annexe 372 females. These figures concerning the great metropolitan district include all classes of the "mentally affected"—waifs and strays—recurring "habitual inebriates," &c., showing the heterogeneous character of the inmates, the kind of data generally presented; to enable us to work out the solution of the question, or form some idea of the prospect of its being reached in the near future so as to settle it.

In the cause, and for the sake of a great variety of interests, it is now obviously desirable that the much debated question of insanity should, if not cleared up—which it can never quite be so long as the existing conditions of human nature exist—be at least put on a more satisfactory and sensible basis, than high-flown ideas can ever accomplish, if only to dispel alarmist apprehension, and check the entirely uncalled for rush of money expenditure. This expenditure has been of recent years in striking contrast with the parsimony and cheeseparing which prevailed a few decades ago, simply because the powers had no confidence in the authorities which then existed—and in consequence imposed various clerky restraints, implying distrust, a fatal clog to departmental government, inasmuch as it starves it down to the vanishing point of all efficiency. But now, as sure as the swing of the pendulum, a new epoch operates when newly-fledged authorities coming to their work with sanguine ideas of reform, and inflated notions of their paramount all-sufficiency for the express purpose, concurrently with lavish responses from the Treasury, previously peremptorily and most unreasoningly denied, assuming that everything must be bad, and rotten, proceed with the attempt to cleanse the Augean stables on an expensive

scale of simple scavenging. Unfortunately, the general public take no interest in the subject of lunacy because it is not associated with any political fermentation. The only chance of arousing their dormant sense of its importance is to bring it home to their pockets. Energetic attempts have been made by writers conversant with the question through the medium of magazines and the newspaper Press, from time to time, to create the nucleus of some public opinion on it, but with very indifferent success. Now, Ireland at the present moment is most exceptionally circumstanced as regards the matter, because different from, we believe, most other civilised nations, its people or their representatives have its shaping and destinies at last entirely in their own hands. If some one strong local body would start with a good and intelligent initiative, commending itself to the emulation of the others, there would be every hope of the establishment of the sound popular system contemplated by the Act on a suitable and economical basis—this—hand in hand with a masterly inspection from a central point would most effectually clear up any mystery there may be as to the alleged increase and propagation of insanity. We think whoever originally drafted this Local Government Act showed an amount of farseeing wisdom, sagacity, and independence in the framing of the lunacy clauses, for which due credit has not been given because the results cannot yet be felt. Feeble attempts have heretofore been made—through the rough and ready agency of Commissions—the resource usually of responsible authorities who are ignorant of the subject themselves; or, foreseeing the facilities afforded for the perpetration of some injustice or favourite job with impunity in arranging lunacy conditions in this country, resort to them all the more readily, though by this time they ought to be pretty well discounted. Thus ten or twelve years ago, when it was easy to see the close of the nonagerian rule of the Lunacy Department was, in the natural course of things near at hand, another inquiry was started, though for all practical purposes, as the sequel showed by a species of drum-head court martial, the department had been summarily tried, condemned, and executed. Later on as the report of the inquiry urged the formation of a Board of Lunacy—under cover of which the condemned system was practically perpetuated—that is, for so long as there remains any ostensible reason for such an obsolete system, terminable only with Home Rule. Probably whatever remained of the wreck of a department, under the new Act, did not too large vested interests make it incompatible, would have been economically utilised in forming a suitable and efficient inspectorial and clerical staff under the Local Government Board.

There are now in Ireland about 20,000 registered lunatics, more than two-thirds of whom are maintained by the Treasury and local rates, and find their lodgment in the district asylums, now to be entirely managed by the local committees. What may be the extent and utility of the operations of the Inspectors

remains to be seen. We presume we shall be afforded glimpses of them in the Blue-books, and we hope they will be commensurate. There are somewhat under 200 criminal lunatics in Dundrum supported entirely by the Treasury, but if Sir Dominick Corrigan's policy had been adopted, which was at once summary and drastic, the irreducible minimum would have been reached, and there would be no occasion to raise the boundary-wall, neither would the term "criminal lunatic" perplex. It is officially reported that according to the Census there are about 5,000 lunatics "at large"—that they are being gradually absorbed into the "registered"—and the presumption is they will ultimately disappear from human ken. Further information might be vouchsafed as to the grounds upon which the unregistered lunatics are regarded to be insane. At page 4 of the 47th Report in Lunacy (Ireland) may be found an interesting table showing the proportion per 100,000 of the population of lunatics. In the year 1880 in a population of over five millions the proportion was 250, and in 1897, with a population of something over four millions and a half it was 430! This would be conclusive, were it not that the factors are based on very uncertain, indefinite, and fluctuating data, and our primary object is to induce the authorities to lay the groundwork of unerring and demonstrable data as the only means, in conjunction with another process, of arriving at a correct inference as to the increase of insanity in the Irish community. Mr. Corbet, M.P., who has written much on the subject, appears to rely mainly on the official statistics. We know the greatest statistician this country ever produced (Dr. Neilson-Hancock) could prove anything from them; but the great bulk of blue-book statistics, especially upon such abstract subjects as insanity, must necessarily be fanciful. We only believe implicitly in, and make reliable deductions from, such statistics as the Chancellor of the Exchequer's Imperial balance-sheet. Mr. Corbet, M.P., pins his faith to the published statistics of insanity, because they are the outcome of that official oracle he helped to deify, and is a firm believer in its increase. He has published many elaborate papers to show this, but his last, if it prove anything proves that every child and descendant of Adam since the foundation of the world is more or less insane—cranky or a crank—and in that view there is no doubt that insanity is increasing and as he reasons, likely to go on increasing.

MODERN IMPROVEMENTS IN DIAGNOSTIC APPARATUS.

IN the interesting address which Sir R. Douglas Powell delivered at the annual meeting of the British Medical Association, the orator dwelt affectionately upon the comparatively recent date at which so many of the diagnostic appliances now generally employed were introduced. Among the senior men there must be many who can recall the first appearance of the stethoscope, and the impor-

tance of this innovation is enhanced by the fact that it was the means of directing the attention of practitioners to the value of physical signs perceptible on auscultation and percussion in the diagnosis of disease, for the recognition whereof the practitioner had previously only clinical observation to guide him. It is really difficult at the present time to form a trustworthy idea of the means which præ-stethoscopic practitioners adopted to arrive at a diagnosis. Doubtless they cultivated other special senses and laid greater stress on direct observation of the patient, a process now discarded in favour of instruments of precision sometimes possibly to the detriment of medical science. Curiously enough the orator went out of his way to decry the use of the perfected instruments which have to a great extent superseded the old wooden tube, and no doubt to some extent his strictures are justified. Each variety of stethoscope presents advantages of its own, and in doubtful and obscure cases the careful man listens with each in turn, thus extending his sphere of observation and confirming his results. The sphygmograph, though a revelation in its way, has rendered more service to physiology than to clinical medicine, but one can hardly contemplate with equanimity the practice of medicine without the aid of the clinical thermometer, yet its introduction, we are told, dates from the days of the late Sir William Jenner. The sudden importance which the temperature assumed in medicine when its use became general has had its drawback in that it paved the way to antipyretic medication, a method of treatment which is in many cases the reverse of scientific, and has in any event been carried to great excess. When we bear in mind that pathogenic microbes develop most freely at temperatures approximating the normal, we may well ask ourselves whether in violently reducing fever we are not thwarting Nature's reactive struggle against the invading organism, in fact it would appear that a given temperature is as normal to a particular disease as a lower temperature is to health. Fortunately the antipyretic wave has passed its apogee, and practitioners are beginning to employ these powerful and even dangerous drugs with caution. Another craze that has well nigh seen its day is the fond delusion that it is possible to attack the germs of disease in their stronghold, the human body, by means of bactericidal and antiseptic products. For this to be possible the agent would require to be possessed of an elective action on the invading organisms, whereas they are all protoplasmic poisons, as inimical to the human protoplasm as to that of the bacilli. It was not until the advance of bacteriology paved the way to the introduction of serotherapy that any such selective action became possible, and even now we are but on the fringe of the subject. The value of bacteriology in the diagnosis and study of the natural history of disease cannot be overestimated, but its application to the preventive and curative treatment thereof, with one or two exceptions, is reserved for the, let us hope near, future. The measures now in progress for the prevention of tuberculosis demon-

strate unquestionably the value of bacteriological data, even when that knowledge has not resulted in the discovery of an immunising serum. Knowing how the disease is spread we are in a position to do something to circumscribe its ravages, and when the public have been educated up to a comprehension of the essentially preventible nature of the disease much good will doubtless attend organised efforts in this direction. Our knowledge of the infectiousness of tuberculosis only dates about a quarter of a century back, and up to within the last ten years the new views met with a very cold reception. Now, one's only surprise is how the fact could possibly have been overlooked. We are at present confronted with the danger that the recognised infectivity of the disease may blind us to the other determining circumstances and conditions which render infection possible and favour the subsequent development of the morbid process. Our efforts to stamp out the disease must needs prove disappointing unless something be done to rectify the conditions which favour its dissemination. We cannot hope to exterminate the bacillus tuberculosis, though we may minimise its opportunities for mischief, and if any great measure of success is to be achieved, it will be by measures having for object to reinforce the resistance of the tissues by improving the hygienic conditions of civilised life. The tendency to the formation of urban aggregations, and the further tendency to exaggerate the density of population by the erection of huge superimposed mansions, are factors which will have to be reckoned with on the other side.

THE ETIOLOGY OF HORSEPLAY.

WHERESOEVER a few men, young in years, or, if not strictly so, young in mind, are gathered together some expression of their physical energy, exemplified by horseplay or "ragging," appears to be inevitable. Nor is this a reprehensible practice so long as it remains free from any taint of bullying. It forms properly a mode through which the cerebral cells of youth are enabled to rid themselves of their natural inclination towards fun and frolic of an active kind, removed from all mental malice or tyranny; a safety valve for the brain cells of those who suffer from the repression imposed by civilisation, at a period of life when desire for physical pleasure is most marked. In every human brain the love of power and for mastery is present, lying more or less dormant, or as occasion affords, more or less active. Naturally it is among the younger members of civilised races that this tendency is most often displayed; the stronger exults in his power of harassing the weaker, and enjoys, like the savage, the anguish and pain shown by his victim. Such tendencies, at least when they are displayed by scions of civilised peoples, necessitate for the future good of the tyrant and his slaves, regarding them as future members of a community in which tyranny and slavery are non-existent, firm repressive measures. But in dealing with the ordinary types of horseplay

which are devoid of malicious intent, and from which the perpetrators fully expect a *quid pro quo* from the victims of their deeds at the first opportunity offered, it should be borne in mind that the natural high spirits of youthful brains are frequently so trammelled by the corset of civilisation as to actually require, and benefit from, such a liberation of natural energy. The subject is of interest to members of our profession because of the outcry every now and then raised over some report more or less coloured as to the disgraceful ongoings of a hospital resident staff. An example happened lately when the residents of the Edinburgh Royal Infirmary were reported to be fond of horse-play out of hours, and through a complaint to their board of managers received a severe "wiggling" regarding their unprofessional conduct. It is a question of some psychological importance whether the occurrence of an occasional "rag" does not yield a greater meed of good to the participants, than harm either to the "ragged" or to the general efficiency of the first-named. Where the proceedings are free from suspicion of tyranny, the man who is unable to take chaff of this physical kind has but little in him. The work of a hospital will not suffer because the resident staff have sought in this way an outlet for their cerebral store of energetic nerve force during hours of independence; it will rather benefit, seeing that it entails so long a term of professional application upon the resident officials in each twenty-four hours. Is the business of the Stock Exchange any the worse conducted because its members, as common report has it, are not at all averse to displays of animal spirits, which usually spell "ragging?" Are they reprimanded by the daily press for them? No; but let the writers of the lay press hear of any such occurrence in a hospital, and what unctuous reproof, what calling upon their Penates to witness that no such depravity had ever been seen; patients, many of them nigh unto death, harassed by the rowdy antics of those responsible for their treatment; physicians in onerous posts behaving like lunatics, &c.; totally forgetting that it is after hours of duty, and within private apartments that the dreadful acts have been committed; that no patient has been disturbed; and that the actors have been employed for most of the day, and of the many days before it, in devoting their time to laborious and careful attention to the sick, thus depriving themselves of all means for a liberation of their youthful physical impulses. Jack is made a dull boy when deprived of play. The brain of youth or while still youthful, however old its owner may be, cannot be rationally expected to pursue the line of a "moudiewort" as the Scotch would say, without detriment to itself, unless allowed some latitude in its manner of expression of revolt. It is more than probable that the cerebral cells endowed with different functions are in health so charged with energy that they can instantly respond to the stimuli specially fitted for them, while if not called upon by stimuli which they expect, for many

must be apathetic by reason of entire disregard, and have been accustomed to, they may be inclined to hint to the governing mechanism that a little outlet would be salutary. Is such a message a crime against civilisation? Is it not rather an indication that the highest civilisation will accompany opportunities freely afforded for the liberation of that natural nervous force which inclines towards physical expression? The Anglo-Saxon love for muscular enjoyments and physical rivalry have much to do with the success of the race. Why then reprobate the harmless exhibitions of similar origin on the part of junior physicians, "cribbed, cabined, and confined," at a time when nature is perhaps most assertive? The pity of it is that the hospitals suffer much from the animadversions of writers in the press, who have forgotten the days when they themselves were young, in the gratification given them, a pleasure closely allied to that of the bully, in their power to ape authority; the power of jealous age over the capacity of youth for an enjoyment it has itself lost.

Notes on Current Topics.

Typhoid Fever and Tuberculosis.

THERE is a noteworthy relationship between the incidence of pulmonary tuberculosis and typhoid fever, a relationship which is borne out by the Registrar-General's annual returns. The steady reduction in the mortality from typhoid fever which has characterised the returns of the last quarter of a century is associated with a corresponding diminution in the mortality from pulmonary tuberculosis. Nor can this cause surprise seeing that the conditions which favour the dissemination of typhoid also in large part favour the evolution of tuberculosis. Ill-ventilated and ill-lighted dwellings, foul and insufficient water supplies, the accumulation of filth and the want of proper drainage both in towns and in houses, not only assist in propagating typhoid, but also favour the dissemination of tuberculosis. As Dr. Seaton points out, by lowering the subsoil water of towns and thus rendering the foundations of houses drier and cleaner, the conditions which promote the vitality and virulence of the typhoid bacillus are modified and removed and, *pari passu*, phthisis is thereby rendered much less frequent. If the time ever arrives when typhoid fever shall have become a thing of the past it may safely be predicted that phthisis will also have become vastly less frequent. These observations are important in that they show to what a large extent these two diseases are under human control. Prevention is, therefore, much more important than cure, and we realise that sanitation is more important and effectual than sanatoria. Of course the channels of dissemination of the two diseases are different though the conditions which favour their evolution are much the same. Moreover, although it is generally assumed that water is the principal, if not the only, vehicle of typhoid infection, we have

serious reasons for suspecting that there are other, hitherto unsuspected, channels, and it is of the utmost importance that these should be identified. The same remarks apply to tuberculosis, and here again it is possible that public attention is too exclusively directed to certain means of infection, others equally worthy of note being ignored. Our motto should be the prevention rather than the treatment of tuberculosis, for our efforts must needs be frustrated in respect of the latter so long as the hygienic conditions of our towns offer every facility for the development of the specific bacillus.

Some New Uses for Thyroid Extract..

IN accordance with the time-honoured custom which requires that when a therapeutical agent has been found useful in one affection, it should be given a trial in others not presenting any obvious analogy thereto, thyroid extract is being experimented with in various morbid conditions. It is already largely employed for the relief of obesity and, in spite of its drawbacks, with a certain amount of success. Then it was recommended in the treatment of acute psoriasis with results which are as yet not well-defined. The next thing for which it was exhibited was that complex morbid condition described *en bloc* as dysmenorrhœa. In some of the cases it is alleged to have given great relief, while in others it proved inert. This indeed is what one might have anticipated, seeing that the causes of dysmenorrhœa are various, and the remedy which would obviate one cause would be unlikely to modify the condition in another. The most recent suggestion is the administration of the thyroid extract for the reduction of fibromata of the uterus. According to the report of a committee of the American Gynæcological Society, based on observations carried out on a series of cases of fibroma uteri, presenting well-marked symptoms, the treatment was followed by distinct amelioration in a sufficient number of cases to make it advisable, if not obligatory, on us to give patients a fair trial of the treatment before resorting to operative measures. It is noted that the relief was specially marked in the so-called "nervous" cases, the patients becoming calmer and more rational. It is not denied that in a fair proportion of the cases observed an operation became, or appeared likely to become, necessary, but possibly further observation will assist us in distinguishing the cases in which this treatment is likely to prove efficacious from those in which surgical intervention alone can be trusted to give relief.

"Christian Science" as Applied to the Lower Animals.

THERE is not much room in this country for the "Christian Scientists," and the sect, the gullibility of the public notwithstanding, is never likely to have any encouragement here. As a matter of fact its practices are too transparently fraudulent. Under all the circumstances, therefore, of the case, it is extraordinary that in America the sect should be afforded opportunities of establishing itself more or less extensively. Indeed, a new Medical Act has just

been passed in Illinois which contains a clause conferring upon the sect a legal status. The clause states that the Act shall not apply to any person who ministers to or treats the sick or suffering by mental or spiritual means without drugs or material remedy, thus leaving the door open to a barefaced system of quackery of which it is easy to foresee that full advantage will be taken. The prevalence, however, of Christian Science in America is shown by the fact that its practices are not confined to the treatment of the ills of human beings; a new phase of the "Science" has arisen, that is to say, "Christian Scientists," are prepared to exercise their art in the relief of the diseases of animals. In this connection an amusing incident is mentioned in the *Journal of the American Medical Association*. A "Scientist" failed to make a diagnosis in the case of a cow that was *in extremis* when he arrived. However, after three sittings of profound meditation the cow made such an excellent recovery that it chased the "Scientist" twice round the barnyard, and he was only rescued from a perilous situation by a hired man with a pitchfork. Possibly if the "Scientists" begin to find that their veterinary department is liable to frequent developments of this nature they will decide to confine their attentions to human beings. At all events in this instance it is quite clear that the cow had no intention of being made a fool of. We may assume that the natural resentment which it displayed was intended as a protest against making it the medium of fraudulently extracting dollars out of the pocket of its owner. Possibly, however, it expected a dose of medicine, but when it found that it was expected to get well under the influence of the "profound meditations" of a Christian Scientist, the animal at once adopted an effectual method of showing its abhorrence of quackery. Pity can only be felt for those persons who prefer to be attended by the "Scientists," and who fail to show the common sense which was apparent in the cow.

Untrustworthiness of Rabies Statistics.

IN the House of Commons last week Mr. Long, answering Mr. Whitmore, said in 1896, the year prior to the commencement of operations against rabies, there were 438 cases in Great Britain confirmed; in 1897 151 cases; in 1898 17, and during the present year so far as it had gone only one case. The Department had now made arrangements for obtaining the same security against the introduction of the disease from Ireland, and so soon as these arrangements were in effective operation, he hoped to be in a position to withdraw the orders from certain English districts. While we congratulate the public on any prospect of the repeal of the futile and ridiculous muzzling order, we cannot abstain from expressing strong doubt that Mr. Long's department is entitled to any credit for the supposed rapid reduction in the number of cases of rabies of which he is so boastful. If a medical scientist claimed that, in the short space of three years, his treatment brought

down the number of sufferers from a specified disease from 438 to 1, the profession would certainly sniff at his statistics and demand unquestionable proofs. In the case of Mr. Long's very gratifying figures that proof would not be forthcoming because he compares succeeding years which have no analogy with each other. In 1896 and 1897 there was, practically, no verification of the diagnosis of rabies either in dog or man. As regards the former, the suspicions of every vet. or policeman were, at that time, taken for gospel, and the 587 cases of rabies then recorded were the result. In 1898 Mr. Long's department arrived at the suspicion that the ideas of a vet. or policeman were not evidence of the existence of rabies, and, therefore, not safe basis for legislation, and an order was made that the diagnosis of the disease should be, thenceforth, when possible, confirmed by bacteriological investigation. Hence the precipitate fall in the supposed frequency of the disease from 151 cases to 1 in two years. Mr. Long's statistics, of which he is so proud, prove, in fact, nothing more than that the muzzling order was begotten of ignorance as to the prevalence of rabies which was, itself begotten of the folly of building up conclusions upon the *ipse dixit* of a vet. or a policeman. We have pointed to that folly many a time, but it was persisted in by officialdom and is now, happily, coming to an end.

An Epidemic of Tetanus.

THE Fourth of July celebration in the United States has always been prolific in accidents of various kinds, and no less than one hundred and fourteen lives are reported to have been sacrificed as a sequel of the last *fête* of the kind. It is a remarkable fact that tetanus was responsible for no less than eighty-three of these deaths, a prevalence which can only be explained on the assumption of the specific bacillus being far more widely spread in the States than in this country for example. We may note *en passant* that the serum treatment did not give very encouraging results, and more success appears to have attended Bacelli's carbolic acid treatment.

The Therapeutics of Liquid Air.

It is of interest to note that investigations have been carried out with a view to testing whether or not liquid air possesses any therapeutic value. In the *New York Medical Record* for July 22nd Dr. Campbell White records the results which he has obtained from its employment in the treatment of many forms of disease. At the outset it may be pointed out that liquid air is not antagonistic to the lower forms of life, and cannot therefore be regarded as a germicide. Dr. White, however, expresses the conviction that from his experience nothing acts so well in promoting the granulation of varicose ulcers, chancroids, and other specific ulcers as this preparation. He has also used it with great benefit in cases of sciatica, herpes, intercostal and facial neuralgia. Again, in lupus he is able to speak encouragingly of

its use. On the other hand so far as carcinoma is concerned his experience of it has not been sufficient to enable him to express a positive opinion. The mode of application to which Dr. White resorts is that of a cotton swab, or by means of the spray. We are not aware that any observations upon the therapeutic use of liquid air have been made in this country, nevertheless it would seem from the above recorded facts that it possesses some therapeutic value and is worthy of a trial in certain diseases.

The Therapeutical Value of Sulphur Fumes.

A MAGNIFICENT sanatorium has recently been thrown open to the public near Naples by the generosity of the Duchess Teresa Ravaschieri for the benefit of persons suffering from pulmonary tuberculosis. It is near the Solfatara, the crater of an almost extinct volcano. Gases and smoke still escape from the numerous crevices and fissures, and the air laden with sulphurous fumes, is popularly supposed to have a beneficial effect on consumptives. If this be correct our native sufferers need not go so far afield for their treatment, seeing that the air of the Metropolitan Railway fulfils every indication. If the railway authorities could be persuaded to render available a special car for the use of phthisical patients on the payment of a small sum in addition to the ordinary third-class fare, no doubt a certain *clientele* would be attracted. If the prospect of passing several hours daily in the depressing darkness of these subterranean passages be held to constitute a drawback the waste air might be pumped into the rooms of a sanatorium constructed *ad hoc*. Sulphur fumes, by the way, used to be recommended in the treatment of whooping-cough, though we have not, so far, heard of any cures attributed to the methodical use of the "Underground."

The Suppression of Street Noises.

THE life of the average citizen is becoming more tolerable, so far as street noises are concerned, a happy state of things which is due, not to the fact that he has become accustomed to such nuisances, but because the streets are quieter than they used to be. In a certain measure a good influence has been exerted in this direction by the London Society for the Suppression of Street Noises. Although only in the second year of its existence the Society, as its report for the past year shows, has been steadily pressing forward an admirable campaign against the soul-disturbing costermongers and newsboys, who make the thoroughfares hideous with their yells and howls. Moreover, it is satisfactory to note that the Society has a well designed programme in the pursuit of which its members intend to expend their best energies. For example, among their objects of reform are included the compulsory fixing of India-rubber tyres on all vehicles, floors of the same material for milk-carts, the establishment of kiosks in place of the screeching newspaper boys. But even if all these reforms were successfully attained, many more noises would still be left to be dealt with. The bawling coal hawker, for instance, is an intolerable nuisance.

and the irritating, expressionless, metallic clang of the barrel-organ should be banished altogether from the streets. Possibly, however, when the London Government Act comes into force marked improvement will be noticed in regard to the prevalence of street noises, inasmuch as the new municipalities have been empowered to make by-laws for regulating and suppressing such nuisances, and there is every reason for supposing that full advantage will be taken of the clauses in the Act relating thereto.

The Extermination of Malaria.

THE etiology and prevention of malaria is one of the most important medical questions of the day, and, therefore, the investigations of the Commission under Major Ross, I.M.S., sent out by the Liverpool School for Tropical Diseases, will be looked forward to with great interest. Meanwhile Major Ross makes some important suggestions in regard to the prevention of malarial disease in a paper contributed to the current number of the *Indian Medical Gazette*. In the first place, he claims that it is now generally admitted that the mosquito theory of the disease is correct, and hence he affirms that, in order to eliminate malaria wholly or partly from a given locality, it is necessary only to exterminate the various species of insects which convey the infection. Investigation has shown that the insects are always hatched from aquatic larvæ or grubs which can live only in small stagnant collections of water, such as pots and tubs of water, garden cisterns, temporary pools of rain water, and so forth; and thus it is suggested that in order to get rid of the insects from a locality all that will be necessary will be to empty out, or drain away, or treat with chemicals the small collections of water in which their larvæ must pass their existence. This would seem to be a very easy solution to the problem, but its practicability will depend upon circumstances. Different mosquitos invest different water localities, so to speak, some breed in pots and tubs of water, others exclusively in cisterns, ditches, and drains, others again only in shallow rain-water puddles. Therefore for practical results, Major Ross points out that it will be essential to ascertain not only what special mosquitos do carry human malaria, but also the nature of the habits of the dangerous varieties. From all these facts it will be readily gathered how large a field of inquiry the malarial question is, and how promising the prospect is, that we are within a measurable distance of gaining headway against the disease.

The Reform of the Medical Services.

It will be interesting to note the effect, if any, which Professor Ogston's address has upon the Admiralty and War Office authorities, and it would also be interesting to learn the feeling with which it has been received by the officers of the Services concerned. So far only one officer has publicly expressed himself regarding the address—namely, Surgeon-General Harvey, who proposed

the vote of thanks to Professor Ogston, in the course of which he admitted that some parts of the address would cause a certain amount of criticism. Nevertheless he agreed that in many directions great improvements were possible in military as well as in naval, matters. It was clearly, however, in no hostile spirit that Professor Ogston took up the position that he did upon this question, and we are glad to see that Surgeon-General Harvey admits that this is the case. The latter expressed the hope that the address would be received in the spirit in which it was intended—namely, as one of kindly criticism with the object of improving the Services on which the Army and Navy depend. We would fain express the same hope, but at the same time we trust that Professor Ogston's criticisms will be acted upon. The washing of dirty linen in public, an expression which may be applied to Professor Ogston's indictment, is always a process from which to shrink. But sometimes it is necessary, especially in the advocacy of much-needed reforms, and now that the unpleasant duty has been discharged, every effort by those in authority should be made to prevent any such charge against the Services being brought again.

Smoke Prosecution.

THE question of smoke prevention is one of vital importance to the future of town populations, yet it cannot be said in any real sense of the phrase to be efficiently handled in any large town in the United Kingdom. Last week a London vestry successfully prosecuted a well-known firm of restaurant keepers for allowing black smoke to issue from their chimneys so as to constitute a public nuisance. The whole question of smoke abatement demands urgent attention. The present failure to cope with the evil is due mainly to two facts—namely, the want of efficient sanitary inspection and the disinclination of magistrates to convict. The first point is only a part of the wider question of the insufficiency of the staff of sanitary inspectors that mars the health administration of local authorities all over the kingdom. The London County Council has just issued a report dealing with the whole subject. While the duty of enforcing the law in the first lay with the various sanitary authorities, yet in their default, the Council has a general power to act. With the assistance of the Metropolitan police the Council has procured evidence of no less than 3,699 offences for use in prosecutions by local bodies. Of the large number of infringements in which proceedings were taken, the majority appear to have been either dismissed by the Metropolitan police magistrates, or to have been granted such long periods in which to carry out necessary alterations as to render conviction well-nigh worthless. From these various considerations it is hardly to be wondered at if the vestries are lax in dealing with this class of offence. Some day we may hope that magistrates may be grounded in the first principles of public health and of medical jurisprudence.

Is the Plague in Oporto?

THE question as to whether plague had at length invaded Europe was pointedly raised in the columns of THE MEDICAL PRESS AND CIRCULAR in our issue of August 2nd. The subject, which is undoubtedly of prime importance to the welfare of the Continental population, was suggested by information of an exclusive nature that was placed in our possession from an authoritative source. Nine days later the *Globe*, a leading London evening newspaper, thought fit to notice the "suggestion that the cases of suspicious illness which have recently occurred at Oporto are in reality cases of Indian plague." We are glad to learn that the editor, although he does not acknowledge the source of the "suggestion" agrees with us, *verbatim et literatim*, in the hope that the matter will be at once investigated, and his powerful influence, coming as it does ten days after our opening shot, should go far towards convincing the Portuguese authorities. Ten days, however, is a long period of delay in dealing with so acute a disease as plague, especially when the actual bacteriological diagnosis could be made within a few hours. So comforting, however, is the support extended by the editor of the *Globe* to a medical contemporary that we cannot refrain from expressing hearty approval of his concluding sentence, especially as it rings a complete echo of a previous generalisation of our own:—"It is of the utmost importance to the rest of Europe," he remarks, "that it should be known without delay, whether the plague really has or has not made its appearance in Portugal."

Glycerinated Lymph.

IT appears that complaints have reached the authorities of a want of uniformity in the action of the Government calf lymph, and these shortcomings were recently the subject of several questions in the House. It is admitted that there has been some ground for complaint, and careful inquiry has been set on foot in order to throw light upon the cause of the deterioration. As we are not in possession of the allegations we cannot discuss the reasonableness of the criticisms, but we may remark that it is idle to expect that any lymph, however prepared, will give absolutely uniform results under all circumstances. It is surmised that the sudden changes of temperature to which the lymph has of late been subjected may account for certain specimens proving inert, but, apart from the varying factor of susceptibility, there is the personal factor, that of the thoroughness of the operation and the possibility of subsequent manœuvres having for object to frustrate the success thereof. The Government department in charge of the distribution of the vaccine is at present barely able to cope with the demands of public vaccinators, the average demand being close upon two thousand tubes daily, and, for the present at any rate, private practitioners will be left to shift for themselves. Not, indeed, that this is any hardship, inasmuch as there are plenty of trustworthy lymphs on the market at prices well within the reach of the poorest.

The Prolonged Heat.

THE prolonged heat-wave that is still swamping Great Britain has brought with it the usual train of seasonal diseases. Diarrhœa has been steadily increasing in its death-rate for some weeks past, and is claiming to the full its wonted tax of victims from the baby population. The direct relation of this most fatal malady—we are speaking of its acute summer form—is so remarkable that it is somewhat curious that efficient preventive measures have not arisen from the constant presence of this remarkable condition. As everyone knows, the prevalence of the serious aspects of the disease closely follows the curve of the deep-air temperature as registered by the three-foot thermometer. Since the classical investigations of the late Dr. Ballard little has really been learnt as to the essential facts of this most devastating disease, and a short attractive field of scientific investigation awaits some future worker in practical pathology and preventive medicine. Indeed, it is difficult to conceive any subject that in our existing state of knowledge, or want of knowledge, presents issues fraught with greater importance to the community. In Paris the heat-wave has been accompanied by a considerable increase of cases of typhoid fever, happily of mild type, which have reached a maximum of incidence not attained since the year 1894. When the man in the street asks what is the moral of it all, what shall the scientific physician answer? Verily, so far, perhaps the most if not the only answer of any value is to boil all milk and water before use. But what is the traveller and the tourist to do? Well, either carry his own little boiling apparatus, or drink wine *pace* the teetotalers.

Coventry Provident Dispensary.

IT is to be hoped that a conclusive phase may now be started by the Council of the British Medical Association in its attitude towards institutions of this nature. Since the strong resolution passed last year at the Edinburgh meeting it was natural to imagine that the profession of Coventry would follow up the matter. The Association has at a general meeting now called on the Council by a unanimous vote to demand from these dispensary doctors a reason for continuing their connection with the institution. We hope the Council will be resolute in the matter, and not stultify itself by failing to assert and enforce its opinion. This dispensary has been shown to be a most offensive affair from a professional standpoint. In many respects it is worse than any medical aid association. A lay committee farms out professional aid to substantial people. Funds over which the medical staff have no control are put out on mortgage, and managed by committee. The institution is riddled with abuses of every conceivable nature, and it is high time that the British Medical Association should take steps to purge itself of men who, in spite of repeated remonstrance, maintain their connection with such a body. Future developments of this matter will be awaited with considerable

interest. The new President of the Council is, we understand, in hearty sympathy with the aspirations of the general practitioner, and it may be anticipated that greater vigour will be infused into the future legislation of the body.

Immunity of the Abortion Quacks.

THE syndicate who trade under the name of Madame Frain have been acquitted of the criminal charge of selling abortion remedies. At the trial their counsel scarcely ventured to deny that they advertised largely to entrap married women who did not desire child-bearing, and unmarried girls who—for obvious reasons—entertained the same feeling, having “got themselves into trouble,” and the evidence went to show that the speculators reaped a golden harvest by blackmailing such persons. Nevertheless, they were acquitted, as we anticipated. Why? The difficulties of a successful prosecution in such a case were explained some two years since by a very explicit communication to the Medical Press from the Public Prosecutor. He pointed out that a prosecution might be maintained by any one of three parties—(a) the Crown, for using drugs for felonious purposes; (b) the Pharmaceutical Society, for selling poisons without qualification; and (c) the victim, for having obtained money under false pretences. Of these, the last-named only was likely to succeed in a prosecution, inasmuch as the false pretence would be easily proved by showing that the stuff supplied for abortion purposes could not by any means produce the desired effect. But it will be easily understood that a private prosecutor is never forthcoming in such a case. No married woman could be induced to swear in the witness-box that she took drugs to prevent conception, still less would an unmarried female make the same confession. For this reason the prosecution of such criminals devolves upon the police or the Pharmaceutical Society, for whose case it is indispensable to prove that the stuff supplied contained poisonous drugs in material quantity. To show this has now been found impossible, inasmuch as the stuff is mostly dirty water, with no abortifacient potency whatsoever. The prosecution endeavoured to show that it contained material quantity of “bitter apple” and other emmenagogues, but it failed to show that the quantity was enough to bring the vendor within the grasp of the law, and an acquittal followed. There seems to be no escape from this legal *impasse* except an Act to make the felonious *intention* a felony.

The Hospitality at the Portsmouth Meeting of the British Medical Association.

ONE of the most general subjects of comment at the recent meeting of the British Medical Association in Portsmouth, was the excellent arrangements made for the entertainment of the visitors, and the lavish scale of the hospitality. Upon this matter a universal opinion prevailed that the hospitality extended was such as to make the Portsmouth meeting always a memorable one. Not only were the

guests provided for in a manner worthy of the occasion, but also in a manner befitting the great naval and military centre in which the meeting was held. It would be invidious to single out any special host whose hospitality contributed to the pleasure of the meeting, where so many of the leading residents in the district extended a welcome to the members of the Association. But, perhaps, mention should nevertheless be made of the part taken in this regard by the Mayor of Portsmouth, Alderman Scott Foster. Undeniably the Association is indebted to him in various ways. In giving a prominent official lead to the proceedings in connection with the meeting he set the example to others to do their best to memorialise the occasion. Altogether, from the Mayor downwards, the hospitality shown at Portsmouth was such that the counter attractions in some degree depleted the attendance at the sections.

Unqualified Practice under the Companies Acts.

THE executive of the British Dental Association has issued a circular to its members, urging them to support by all means in their power the objects of the Companies Act of the present year, which deprives commercial syndicates of the right which they claim to practise medicine, surgery, dentistry, and midwifery without qualification. The Association points out that any unqualified person, who may have got himself into trouble by infraction of the Dentists Act, could escape all risk or inconvenience by registering himself as a company, it having been decided by the High Court that a company is not bound by the same law as an individual. The Association calls attention to the attempt of which we have some time since given warning, of certain persons in Dublin, who call themselves the Dr. Bland Company, to work this decision to their own advantage, and, also, of certain other persons seeking to follow the example. Fortunately two difficulties stand in the way of these enterprises. An unqualified person may be prosecuted in the midst of his medical or dental practice if it can be proved that he represented himself to be a registered practitioner—a statement which it ought not to be difficult for an astute person to get out of him. A qualified practitioner, on the other hand, who associates himself with such unqualified persons may, and should be brought before the General Medical Council for “covering,” and expunged from the Register for “infamous conduct in a professional respect.”

Ill-Health of Dublin.

THE last three weeks—as reported upon by the Registrar-General—have marked a rapid and serious increase in the prevalence of disease in the city. In the week ending August 5th, the total mortality had gone up to 33.3 per 1,000, owing chiefly to the great increase in the death-rate from zymotics. In that week the zymotic deaths jumped from 43 to 71, in consequence of the epidemic of measles already referred to, and the great prevalence of children's diarrhoea.

Testimonial to Professor Purser, of Trinity College, Dublin.

A MOVEMENT, of which notice has already appeared in our columns, has been set on foot to perpetuate Professor Purser's long services to the School of Physics as Professor of Physiology and Institutes of Medicine. The intention is to found a Purser medal to be offered for competition at the same M.B. examination of each year, the award being for the highest marks scored, presuming sufficient merit has been shown. Subscriptions are limited to the Professor's past pupils, and to the sum of one guinea. The Hon. Treasurer is Dr. W. S. Haughton, of 30 Gt. Fitzwilliam Street, Dublin, and local secretaries have taken the matter in hand in various English and Irish teaching centres.

THE Right Hon. A. J. Balfour, M.P., has consented to take the chair at a Festival Dinner at the end of November in aid of the fund in course of being raised to provide new laboratories at King's College, London.

SIR MICHAEL FOSTER, the new K.C.B., has been duly invested by Her Majesty with the riband and badge of the Civil Division of the Second Class of that Order, a distinction which gives an official *cachet* to a long and useful scientific career.

SIR HENRY FRANKLAND, F.R.S., has died in Norway, whither he had gone on a fishing expedition. Deceased was not in the medical profession, although intimately connected with it as a voluminous writer on chemistry, and as professor of chemistry at Owens College, Manchester, and St. Bartholomew's Hospital, London. These positions were subsequently resigned for a Government appointment, from which he retired some time since. Sir Henry was in the seventy-fifth year of his age.

THE INTERNATIONAL CONGRESS OF OTOTOLOGY.

THE Sixth International Otological Congress met last week at the Examination Hall on the Embankment, where Professor Urban Pritchard presided over upwards of three hundred specialists from all parts of the world. We publish elsewhere his inaugural address, which gives a brief history of the progress of otology from the dawn of history up to date; but, in respect of the proceedings, we can only express our regret that they are, perforce, very meagre, owing to the want of the usual facilities. In this respect the lay press appear to have met with greater consideration than the medical press, not even a programme having reached us.

There is a very general impression among medical men, if not among the laity, that otology is a somewhat limited and sterile field of activity. As is the case with many other departments of the healing art, otology is not to be judged exclusively by purely curative results achieved. Once the delicate and complicated apparatus which serves to convey mechanical vibrations to the sensorium is destroyed, art can do little or nothing to remedy the defect. What the science of otology does teach us is the possibility of modifying or averting the destructive diseases which,

if allowed to proceed unchecked, ultimately impair or destroy the sense of hearing. Investigation of the conditions which lead to deafness incriminates pretty well all the adjacent cavities and structures, and thus the field of inquiry is widened. No one, nowadays, is ignorant of the role played by adenoid vegetations in the production of deafness, and defects, structural or acquired, of the nose, are well known to tend in the same direction. For this reason it is as difficult to mark off the ear as a speciality as it is to study one branch of physics without taking cognisance of the others. It may appear that we have spoken rather slightly of the curative resources of the oral surgeons, but their inability to relieve in so many of the cases that come to them is merely due to the fact that the mischief has been done before their assistance is asked. With the advance of otological science it is to be hoped that people will learn the importance of seeking skilled advice before irremediable damage has been done, that is to say, at a stage when science may still have something to say.

Dr. Macnaughton-Jones, as President of the British Gynaecological Society, and one of the Reception Committee of the Congress, gave a dinner to some of the foreign visitors to meet the President of the Congress and its officers. The dinner was held in the Café Monico, where about sixty guests sat down. The Chairman gave the toasts of "Our Queen" and "Our Foreign Visitors." The latter was responded to by Professor Politzer, who dwelt on the hospitality shown by the British otologists, and which, he said, could not be surpassed. He also referred to the teaching and practice of the great London hospitals, concluding by proposing the health of their host. Russia was responded for by Dr. Benni, Italy by Professor Grazi and Dr. Bobone, Germany by Dr. Hartmann, Switzerland by Dr. Rohrer, America by Dr. Ewart Norway by Professor Uchermann.

Sir Crichton Browne, in a most felicitous speech, proposed Otology, humorously pointing out where such departments as gynaecology and psychology touched hands with otology, also dwelling on the great advantages of such a Congress as this in educating the public to the need for a greater recognition of the claims of otology as one of the most important of the special departments of medicine, as well as drawing the attention of the Universities to the need for enforcing a special standard of knowledge in this department by making otology one of the special subjects of the examinations for their degrees. Dr. Moure, of Bordeaux, the President Elect of the next Congress, which will be held in Bordeaux in 1903, responded to the toast. Dr. Luc, of Paris, proposed a greeting to the President of the Congress, Dr. Urban Pritchard, to which the latter responded.

In addition to the foregoing, the following were among the principal guests:—Prof. Avoledo, Milan; Dr. F. Alt, Vienna; Dr. Barkan, San Francisco; Dr. Brieger, Breslau; Dr. Barr, Glasgow; Prof. Capart, Brussels; Dr. Duchesne, Liege; Dr. Dench, New York; Sir James Dick; Prof. Faraci, Sicily; Prof. Gradenigo, Turin; Prof. Guye, Amsterdam; Dr. Knapp, New York; Prof. Lucae, Berlin; Dr. Moore Lindsay, Salt Lake City; Prof. MacEwen, Glasgow; Dr. Meniere, Paris; Dr. Sune-y-Molist, Barcelona; Dr. Story, Dublin; and the Editors of the three principal medical journals, the *Lancet*, *British Medical Journal*, and *MEDICAL PRESS AND CIRCULAR*.

Most of the officers of the British Organisation Committee of the Congress were also present, and some leading Fellows of the British Gynaecological Society.

Various national airs were played by a stringed orchestral band during the evening. The reunion was most enjoyable, and there was but one opinion on the part of all who were present as to its great success.

Annual Meeting of British Medical Association,

HELD AT
PORTSMOUTH, AUGUST, 1899.

THE ANNUAL EXHIBITION.

(Concluded from our last issue.)

Messrs. FAIRCHILD BROS. AND FOSTER (Snow Hill, London). This firm had a handsome exhibit, prominent among their products being Zymine Peptonising Tubes, Peptogenic Milk Powder, Panopepton, and Pepsencia. Zymine Peptonising Tubes, as everyone knows, contain powder for the preparation of peptonised milk in an accurate and portable form. Peptogenic Milk Powder is an excellent preparation for the modification of cows' milk for infants. Panopepton is a bread and beef preparation in a fluid peptonised form. It is palatable and freely assimilable, and is most valuable in sleeplessness when this is due to excessive fatigue or malnutrition. Pepsencia is a most pleasant preparation of pepsine in the liquid form, is made directly from the peptic glands of the stomach, and contains all the constituents of the gastric juice. It is recommended for indigestion, and makes delicious junket.

ALLEN & HANBURY'S showed an extensive assortment of surgical instruments, and all up-to-date aseptic appliances. The Allenbury's Milk Pasteuriser, exhibited at the Association for the first time, is of commendable simplicity, and should certainly come into vogue as a popular milk steriliser. We propose noticing this instrument more fully in our next, with an illustration.

They also showed a new aseptic ligature box, suggested by Mr. Jordan Lloyd, consisting of a silver-box with a porcelain reel inside, a capital and simple sterilising chamber. A new anastomosis forceps by Dr. Laphac, an American surgeon, suitable for abdominal surgery. A catheter steriliser, by which a jet of steam is drawn through the catheter. A new torsion spring balance for dispensing purposes scaled to grammes and decigrammes, a delicate and durable instrument of American origin. No weights are needed, and it is dust-proof when out of use; also an excellent new centrifuge producing 5,000 revolutions per minute.

The same firm showed a collection of their renowned pharmaceutical products. Among them were capsules, capsules in gelatine, coated compressed medicines, and the well-known Allenburys Foods. Samples of the latter were offered to the visitors in the form of ice cream which proved most acceptable in the heated atmosphere of the drill hall. Phosote and taphosote were new preparations for phthisis, being phosphate of creasote and jannophosphate of creasote in a more pleasant and assimilable form than the crude drug.

Mr. THOS. CHRISTY, who is specially known in connection with the importation of new and rare medicinal plants and drugs, had an extensive display of his specialties. Adeps Lanae, B.P., Christia, Pictet's ethyl chloride, Neo-kola, (said to be the only preparation which contains as much as 99.75 per cent. of pure kola) Stearns' wine of cod liver oil, hæmoferrum, glandulen, &c., all of which have been referred to in these columns when first introduced. As a new departure he also showed some preparations in which fluorine has been used for the first time for medicinal purposes, and with names significant of their uses, fluor-rheumin for rheumatism, and epidermin, which is claimed to be a specific in certain skin diseases.

THE MALTINE MANUFACTURING CO. showed a large exhibit, in which the gold medal "Maltine" occupied a foremost place. The compound preparations were also represented, such as maltine with hydrophosphites, with cascara sagrada, and with yerbine.

CARRICK & CO. were strongly in evidence with a large assortment of their special food preparations. There is no need to go through the list of these well-known pre-digested articles, of which the mainstay is the "liquid peptonoids." The "soluble food" is another well-known product of this firm, and is intended for children. "Maltoline" consists of malt extract, cod-liver oil, and hydrophosphites of lime, soda, and iron.

MAW, SON, & THOMPSON had a large and imposing display of surgical instruments, including all the accessories of aseptic surgery. To go through this exhibit systematically would be to revise the elements of a comprehensive surgical education. Some idea of the size and detail of this remarkable stall may be gained from the fact that the mere list of its contents occupied seven pages of the official catalogue. The instruments required in every branch of special surgery were shown in latest pattern.

Messrs. DOWN BROTHERS showed an aseptic operation theatre, fitted complete in every respect. An inspection of this exhibit would give the modern surgeon an object lesson in every detail of the most advanced methods. With regard to surgical instruments, especially those for aseptic use, this enterprising firm produced a thoroughly practical and comprehensive exhibition. The stall formed one of the familiar features of the Annual Exhibition, and need not be entered into in greater detail.

THE ANGLO-SWISS MILK COMPANY had their usual exhibit of Milkmaid brand condensed milk; of "ideal" milk, an unsweetened product; and of their preserved milk combinations with cocoa, chocolate, and coffee.

THE BOYRIL COMPANY occupied a good space with their well-known food products. Their special emergency foods, as supplied to various Arctic and military expeditions, were in evidence, as also their "staminoids" for tourists, cyclists, and other athletes. A good preparation is the virol, a fat food for children, and also marrol, a similar article for adults. Liquor carnis (Caffyn's) is known to most medical men as an uncoagulated albumen.

BURGOYNE, BURBIDGES & Co. had an exhibit that included several novelties. Acoin (Heyden) is a new local anæsthetic, which is said to be more lasting in its effects than cocaine, as well as being non-poisonous. Hyrgolum is a water-soluble metallic mercury, which is best used in the form of ointment. It is claimed for this drug that it does not irritate the skin. Space does not allow us to mention in detail several other valuable novelties shown by this firm.

MR. W. MARTINDALE had his usual display of elegant and practical pharmaceutical products. His bougies, nasal and urethral, were in force, and will repay the close attention of every general practitioner.

JET'S SANITARY COMPOUNDS COMPANY had an imposing show of preparations of their well-known disinfectant fluid, and also of their valuable creolin.

Messrs. SCOTT AND BROWN showed their well-known cod-liver oil emulsion, which is so appreciated all the world over that it needs no more than passing mention in the present notice.

Messrs. E. ARCHER & Co., Great Malvern, showed their dry old cognac, which we can recommend as being thoroughly mellow and of fine flavour. This opinion is borne out by the published analysis of the spirit itself.

Messrs. BAYER & Co.—In our notice of this exhibit last week we referred to one of the products of this firm as "Tannophen," by a clerical error, instead of *Tannopine* (Hexamethylenetetramin.) As the chemical name of the product indicates, Tannopine is a combination of Tannic Acid and Urotropin, and it was to this preparation we referred.

Correspondence.

We do not hold ourselves responsible for the opinions of our correspondents.

THE CONTROL OF THE BRITISH MEDICAL ASSOCIATION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—It is clearly manifest that the members will have to take a decided stand if they mean to assert their rights. The Council of the Association seem to be of opinion that they are an autocratic body, and can do exactly as they please. It must not be lost sight of that the Council consists (or should consist) of the representatives of the branches, and are sent by the members to

represent their (the members) views. It has unfortunately been the case that numbers of branches have not hitherto asked their representatives to give an account of their stewardship, and it is also unfortunate that the members have almost invariably sent the same men to represent them at the Council.

It may be asserted as an axiom that in all elections, unless there is a fair amount of opposition, the representatives will take little trouble to consult their constituents. We must bear in mind the fact that the Council is simply the Medical Parliament, and we must, in our individual branches, assert our right not only to obtain the views of our representatives, but also to have a record in the journal of the way they vote. Until the Council ceases to sit as a private committee, we shall never know the true inwardness of its proceedings. Is there any good reason whatever why the meetings of our Council should not be open to the Press? The Council could, as the General Medical Council does, deliberate in private when necessary, but in the conduct of general business there appears no good reason why a public body like our Council should not have its deliberations reported both in the lay and in the medical press.

We talk about the close corporation of the College of Surgeons, but is that corporation half so conservative as the British Medical Association and its Council? I shall at a future time have a few remarks to make about the annual meetings, and the way the business part of them is conducted.

I am, Sir, yours truly,
August 13th, 1899. A PROVINCIAL MEMBER.

Laboratory Notes.

JOHANNIS POTASH WATER.

A CHEMICAL analysis of this water, which is produced by the addition of bicarbonate of potash, at the Johannis Springs in Germany, to the Natural Johannis Water, shows that the statement as to the amount of potassium bicarbonate present is precisely accurate. We find 7.8 grains of potassium bicarbonate per small bottle (which is about one third of a pint). Now that potash and soda water are no longer official in the 1898 edition of the British Pharmacopoeia, medical men will be glad to know of a water that they can recommend to their patients as of unquestionable purity and of uniform composition, for Johannis Potash is practically a natural water, the pure carbonic acid gas, to which it owes its effervescence, being natural to the water itself. Far too many of the "potash waters" of commerce are very variable in the amount of potash they contain, and many are of doubtful organic purity, being simply made from the local town supply, which may be subject to pollution, and is, in many of the smaller towns, seldom or never analysed. There is a popular delusion that an aerated water (no matter what brand) is safe to drink, because the carbonic acid gas destroys any bacteria that may be present. This is a fallacy, and we strongly urge our readers to trust only to well-known makes of undoubted purity, such as the one in question.

Literature.

SIMPSON'S CEREBRAL SYMPTOMS. (a)

This monograph is the result of a conscientious study by Dr. Christian Simpson of what may be called the material relations of mental phenomena of a morbid kind, and the range of observation is not the limited one of an asylum; for the author has given us the benefit of general hospital study and observations as well. Cerebral and mental symptoms and their correlation to somatic disease, anaesthetics, toxic agents, traumatic and surgical procedures is a large subject for a gradua-

(a) "Cerebral and Mental Symptoms." By J. C. Simpson, M.D. London: John Bale, Sons, and Daniels Ltd.

tion thesis, and too large for anything like exhaustive treatment in a small volume. But, as we have said, the author has conscientiously plodded through his work, and if the pages are sometimes dry, the matter condensed, and the style and treatment lacking in originality, we may commend the work for its references and its practical usefulness. Undoubtedly there is a wealth of bibliographical reference, and an author who culls largely must inevitably sacrifice style and literary attractiveness. Such authors deserve thanks for labour which is inestimable, and help which is invaluable. The later parts are less hampered by references, and the surgical section is of great clinical value. The question of toxic influences is one which still calls for elucidation, for clinical chemistry has much to clear up before we can be sure that we have certainties to deal with.

MORRIS ON THE SKIN. (a)

THE appearance of the second edition of this work will be welcomed by those who make a special study of diseases of the skin. The author has a lucid literary style, which lends to his subject an attractiveness for which we often have to look in vain in medical textbooks. The present edition has been increased in value by the addition of much fresh matter and of several plates, while at the same time an effort has been made to keep the book within reasonable limits. The pathology of skin diseases, if we take it comprehensively, must still be regarded as being in a tentative stage. A vast number of observations have been made, but the great generalisations have yet to come, or, at any rate have yet to be accepted. For instance, the cause of so apparently simple and definite a group of symptomatic phenomena as the drug eruptions remains undetermined. Morris rejects the theory of direct glandular irritation, and advances the unsatisfying explanation of angio-neurotic origin. Indeed, throughout his book he adopts largely the classification of Leloir, who appeared to attribute nearly all possible cutaneous maladies directly or indirectly to nerve influences. With regard to eczema he defines that term as "a catarrhal inflammation of the skin, originating without visible external irritation, and characterised in some stage of its evolution by serous exudation." That definition excludes all forms of inflammation of the skin caused by chemical or mechanical agents. The distinction may be convenient, but it seems to us hardly necessary outside the class-room. All who want a concise, clear, and well written *precis* of our present knowledge of this branch of medical practice will do well to get this book.

PRIMER OF PSYCHOLOGY AND MENTAL DISEASES. (b)

THIS small book is intended for asylum attendants and nurses, and also for medical students. For the latter class it is quite insufficient; for the former it is rather too much. The author has therefore fallen between two stools. The opening pages begin with definitions, e.g., *psychology*, *biology*, *physiology*, *life*, and a rudimentary description of animal evolution. The attempt to give the average citizen an idea of what mind is, has been a failure. To try to give an asylum attendant a real working conception, by using the language of the mental philosopher, even when simplified by definitions, is a hopeless waste of energy. To say that a sensation is an impression made upon an organ of sense is misleading, the nervous reception of the impression is physical not psychic. Then, in speaking of the causation of insanity, it is not correct to say that among the constitutional and evolutionary causes are pubescence and adolescence. Why, if so, are not all young people insane? As already indicated too much is attempted here for attendants, the style altogether is too pedantic, and there is a want of proportion to the avowed aim.

Medical News.

Irish Medical Schools' and Graduates' Association.

THE summer general meeting of the above Association was held on Wednesday, August 2nd, in the Town Hall, Portsmouth. In the absence of the president, Sir William Thomson, F.R.C.S.I., the chair was occupied by Dr. Jocelyn Swan. There was a large attendance of members, including Surgeon-General Cuffe, C.B., Sir William Kynsey, C.M.G., Lieut.-Col. Boileau, M.D., A.M.S. (Trowbridge), Dr. Dolan (Halifax), Mr. O'Callaghan, F.R.C.S.I., Major A. S. Faulkner, I.M.S., Dr. S. Hamilton (Newport), Dr. T. Neville, Colonel Maturin, R.A.M.C., and the Provincial Honorary Secretary, Dr. J. Stewart (Clifton).

The Council reported that they had had under discussion the question referred to them from the annual general meeting as to the best way of celebrating the "coming of age" of the Association, which had just that day completed its twenty-first year, and that they had determined to mark the occasion by a *conversazione* at the Hotel Cecil, London, on or about November 23rd, after the autumn dinner. The provincial honorary secretary (Dr. Stewart) reported that a considerable accession of new members was expected from the effort now being made by the Council to bring the Association under the notice of the two thousand practitioners resident in Great Britain who were eligible for membership but were not yet enrolled. If the result was equal to their expectations, the Council would have sufficient funds to proceed immediately with an attack upon another of the strongholds of monopoly. Surgeon-General Cuffe said he could not refrain from an expression of surprise that there should be in these days, when the "open door" was so much talked of, any necessity for the Association to carry on this warfare against monopoly. Why should hospital governors in London or any part of England shut their doors against all candidates for honorary appointments except those holding diplomas from two specially favoured London colleges? What right had they to imply, as they did by this exclusiveness, that those who had obtained their diplomas in Scotland and Ireland were not good enough to be allowed even to compete for these appointments? Such an implication was, in his opinion, either impertinence or the result of gross ignorance. He had had a large experience of scientific and practical work done in military hospitals, and he had no hesitation in saying that the very best men in the Army Medical Department were Irishmen. The proper principle to act on in these matters was *Liberté, Egalité, Fraternité*. The medical man should not be trammeled in his choice of a college from which to obtain his higher diplomas; the diplomas of the same standing in each of the three countries should be treated as on an equality; and thus the brotherhood of the profession, to which they were all proud to belong, would be maintained. How could the fraternal feeling be sincere when the Irish College was treated as only a step-brother? How could the public understand that the General Medical Council was a body governing impartially medical education in all three divisions of the kingdom when they see from time to time (in the Liverpool papers, for instance) advertisements reading through the lines of which one can see the cruel words "No Irish need apply"? After some observations from Dr. Hamilton (Newport), Dr. G. Roe Carter, and others the subject dropped. One of the rules was altered so as to provide for six of the elected members of Council retiring each year, and being ineligible for re-election for a twelvemonth. The meeting then adjourned.

Death from Chloroform.

A CHILD, *æt.* four, to whom chloroform had been administered last week in view of an operation for empyema at the Metropolitan Hospital, died on the table. The risks of anaesthesia in these cases are well recognised, so much so that many surgeons prefer to operate without it. Unfortunately the report before us does not give the amount used nor the method of administration, but the child died and the usual verdict was returned.

Kings College Medical School.

THE following is a list of scholarships, prizes, &c., awarded for the session 1898-99:—Recommended for the Associateship—Matthew Louis Hughes; Sambrooke Exhibition—Albert Angelo Myers and Harold Benjamin Day; Medical Entrance Exhibition—Charles Harrison Barber and Herbert Sydney Flook, B.A.; Warneford Scholarship—Thomas Henry Jones, John James and Eardley Lanclot Holland; Senior Scholarship—not awarded; Second Year Scholarship—Matthew Robert Cecil MacWatters; Junior Scholarships—Harold Benjamin Day and Albert Angelo Myers; Tanner Prize—William Henville Lowman; Todd Prize—Frederick Burroughs Jefferiss; Hygiene Prize—Arthur Edmunds; Pathological Anatomy Prize—Arthur Edmunds; Obstetric Medicine Prize—Arthur Edmunds; Medicine Prize—Arthur Edmunds; Surgery Prize—William Henville Lowman; Clinical Surgery Prize—William Henville Lowman; Professor Rose's Surgery Prize—Victor Richard F. Kroenig; Anatomy Prize—Edward Augustine Bell; Physiology Prize—John Alexander Drake; Chemistry Prize—Matthew Robert C. MacWatters and William Wellesley Campbell; Materia Medica Prize—Matthew Robert C. MacWatters.

An outbreak of enteric fever is reported among the boys and girls attending the St. John's Road School, Islington. Between July 28 and August 1 thirteen children of both sexes have been stricken down, and a large number of suspicious cases are being kept under observation in the infirmary.

PASS LISTS.

Royal Colleges of Physicians and Surgeons of Edinburgh and Faculty of Physicians and Surgeons of Glasgow.

At the July sittings of the Scottish Conjoint Medical Board, held in Glasgow, the following candidates passed the respective examinations:—

First examination (five years' course)—Katherine Mary Chapman (with distinction), Archibald M. Laurie (with distinction), James Robert Robinson, Alexander Glen (with distinction), William Adams, Robert C. Blyth, James R. Purcell, William D. Cockburn, Alexander Allan, Patrick M. C. O'Doherty, Alexander B. Young (with distinction), Rudolph Barranov, Denis C. Callaghan, John Webster, John Hutchinson.

First examination (four years' course)—William Barclay, John Willett, John A. Aickin, John J. O'Sullivan, James M. Campbell, John Dunlop, Samuel G. Kinloch, Thomas Dow, Herbert D. Pitt.

Second examination (five years' course)—Harry A. Lunn (with distinction), Robert J. Roberts, Thomas E. Harty, David R. Williams, Michael B. Courty, Hugh Williams, David Moodie, Herbert M'Master, William D. Sutherland, John H. O'Sullivan, James N. M'Morris, Aloysius F. Fleming.

Second examination (four years' course)—Henry J. Fryer, John G. Welsh, John A. F. Hatch, John T. Bell, James Graham, Joseph C. Sheldermine, John Willett, Richard M. Wilkin, Robert G. Whitelaw, James James, Arthur Bryans, Matthew O'Hallaron.

Third examination—David S. E. Macnab (with distinction), George R. Jarvie, John T. Griffiths (with distinction), Robert Wardlaw, Donald Duff (with distinction), John Allan, Adam Fox, George J. Campbell, William Thomson, William Burns, Charlotte M'Crea, James J. Lynch, Joseph O'Mahony, John J. McNicholl, William J. Healy, Frederic Wm. McCay, Stuart Farries, William Mason, John Sykes, Thomas R. Hunter, John Bygott, Winifred Nell, Walter Hibbert, Mary Locke, Katharine E. Gregg, George Goldfoot, Archibald C. Balfour.

Royal Army Medical Corps.

THE following gentlemen obtained commissions in the Royal Army Medical Corps at the Recent Examination in London:—

Harrison, L. W.	2,875	Harvey, F.	2,102
Irvine, F. S.	2,284	Trimble, C. E.	2,086
Morton, H. M.	2,260	Matthews, J.	2,084
Babington, M. H.	2,231	McLoughlin, W. A.	1,940
Richards, F. G.	2,150	Siberry, E. W.	1,816
Knox, E. B.	2,121	Wingate, B. F.	1,805
Roch, H. S.	2,115	O'Reilly, P. S.	1,800

Indian Medical Service.

THE following gentlemen obtained appointments in the Indian Medical Service at the examination held last month:—

MacGillchrist, A. C.	3,151	Thornely, M. H.	2,400
Goodbody, C. M.	2,807	Stephens, L. P.	2,356
Megaw, J. W. D.	2,732	Murison, C. C.	2,335
Thurston, E. O.	2,619	Murphy, W. O. S.	2,261
Steen, R.	1,571	Beit, F. V. O.	2,173
MacLunes, J. L.	2,565	Mackenzie, H. M.	2,139
Gilbert, L.	2,550	Loug, W. C.	2,085
Browne, G.	2,342	Todd, L. B.	2,046
Matthews, E. A. C.	2,497	Corry, M.	1,945
Stokes, T. G. N.	2,415	Beamish, G. C.	1,943
Elwes, F. F.	3,410	Williams, H. A.	1,939

Notices to Correspondents, Short Letters, &c.

✎ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

LOCAL REPORTS AND NEWS.—Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sending them to the Editor.

READING CASES.—Cloth board cases, gilt lettered, containing twenty-six strings for holding the numbers of THE MEDICAL PRESS AND CIRCULAR, may now be had at either office of this journal, price 2s. 6d. These cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

REPRINTS.—Authors of papers requiring reprints in pamphlet form after they have appeared in these columns can have them, at half the usual cost, on application to the printers before the type is broken up.

ORIGINAL ARTICLES OR LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

A CAUTION TO MEDICAL MEN.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—A woman signing herself E. M. Iselton and sometimes Etheridge, has been lately appealing to members of the medical profession in very urgent letters asking for the means to relieve "with proper nourishment" a medical man, who is sometimes referred to as her husband and occasionally as her *fiance*, and who is in "great need and rapidly sinking." Recipients of such appeals should refer to the Charity Organisation Society at the address below.

I am, your obedient servant,

C. S. LOCH, Secretary.

Charity Organisation Society, 15, Buckingham Street, London, W.C. August 9th.

DR. COLLINGWOOD (Birkenhead).—Communication came to hand as we were at press.

DR. EWART'S paper is marked for early insertion.

A MEMBER (Portsmouth).—We fully discussed the question in a leading article last week. We cannot again take up the subject, it is now, or should be, in the hands of members to settle. There is, however, the same apathy and indifference in this as in other matters concerning professional well-being; they appear to expect everything done for them without lifting a hand or making an effort themselves.

DR. BRASSEY BRIERLEY.—We are unable to find space for the discussion on midwives' legislation. We shall deal with this as occasion arises, but for the moment we are disposed to allow the subject to rest.

INCONTINENCE OF URINE.

M. R. B.—In dealing with incontinence of urine in young girls, it is well to restrict the quantity of liquid taken after tea-time, and to awaken them at ten or eleven o'clock to empty the bladder. If necessary fifteen to thirty minims of tincture of belladonna should be given at bed time, according to the age. Should this fail, liquid extract of ergot may be tried. Correct any undue acidity of urine, and inquire as to the presence of worms.

DR. J. E. E.—The action for libel with which we were threatened in the case referred to has not yet assumed a serious aspect, nor indeed do we fear it. We performed a public duty in the matter uninfluenced by any other motive and can calmly await results.

PRAX.—A simple plan for the reduction of troublesome paraphimosis is by the application of an elastic bandage, as tight as the patient's feelings will allow. Within twenty-four hours the most marked oedema will have subsided under pressure, and the constriction can then be reduced. Failing success the only course is to cut through the constricting band, a trivial and not very painful procedure.

BATHYBIUS.—We believe that there is no foundation whatever for any such statement.

Vacancies.

Birkenhead and Wirral Children's Hospital.—House Surgeon. Salary £50, with board, residence, and laundry. Applications to the Hon. Sec., 20, Chapel Street, Liverpool.

Birmingham General Hospital.—House Surgeon for six months. Residence, board, and washing provided. Also two Assistant House Physicians for six months. Residence, board, and washing provided.

Brighton, Hove, and Preston Dispensary (Northern Branch).—House Surgeon. Salary £140 per annum, with furnished apartments, coals, gas, and attendance. Apply to the Assistant Secretary, 113, Queen's Road, Brighton.

Denbighshire Infirmary. Denbigh.—House Surgeon for twelve months. Salary £80 per annum, with board, residence, and washing.

Dundee Royal Lunatic Asylum.—Medical Assistant. Salary £100 per annum, with board and lodging.

Durham County Asylum, Winterton, Ferry Hill.—Assistant Medical Officer, unmarried. Salary £120, with apartments, board, and attendance.

East Suffolk and Ipswich Hospital, Ipswich.—Second House Surgeon, unmarried. Salary £60 per annum, with board, lodging, and washing.

Great Yarmouth Hospital.—House Surgeon. Salary £90 per annum, with board, lodging, and washing. No stimulants found.

Guy's Hospital Medical School, London, S.E.—Demonstrator of Chemistry and Physics. Apply to the Dean.

Macclesfield General Infirmary. Junior House Surgeon. Salary £70 per annum, with board and residence in the institution.

North Staffordshire Infirmary and Eye Hospital, Hartshill, Stoke-upon-Trent.—House Surgeon. Salary commencing at £120 per annum, with furnished apartments, board and washing.

Paddington, London.—Assistant to the Medical Superintendent of the Infirmary, and Assistant Medical Officer of the Workhouse, unmarried. Salary commencing at £100 per annum, with board, lodging, and washing. Personal application to the Medical Superintendent at the Infirmary, 285, Harrow Road, W.

Rochdale Infirmary and Dispensary.—House Surgeon, unmarried. Salary £90 per annum, with board, residence, &c. and laundry.

Roxburgh District Asylum, Melrose.—Assistant Medical Officer. Salary £100 per annum, with furnished quarters, board, washing, and attendance.

Royal Hospital for Sick Children, Glasgow.—House Surgeon and Assistant in the Dispensary for one year. Salary of House Surgeon £50, with board, and salary of Assistant in the Dispensary (non-resident) £80.

University of Durham College of Medicine, Newcastle-upon-Tyne.—Lecturer in Midwifery and Diseases of Women and Children.

Victoria Hospital, Folkestone. House Surgeon. Salary £90 per annum, rising to £100, with board, residence, and washing.

Warrington Infirmary and Dispensary.—Junior Resident House Surgeon, unmarried. Salary £100 per annum, with furnished residence and board.

Appointments.

CROMPTON, H. J., M.B., B.Ch. Vict., Senior House Surgeon to the Ancoats Hospital, Manchester.

DENT, E. A., M.B., C.M. Edin., Medical Officer of the Cheltenham Provident Dispensary.

GREENHALGH, A., M.B., Ch.B. Vict., D.P.H., L.R.C.P. Lond., M.R.C.S., Medical Officer of Health for the Borough of Accrington.

KELLY, CHARLES, E. M., M.D., M.S. Lond., F.R.C.S., District Surgeon to the City of London Lying-in-Hospital, City Road.

MELLING, W. T., M.B., B.Ch. Vict., Junior Surgeon to the Ancoats Hospital, Manchester.

MONDY, S. L., CRAIGIE, M.R.C.S., L.R.C.P. Lond., Deputy Certifying Surgeon for the Poole District, Dorset.

NUTTALL, T. E., M.B., C.M. Edin., a District Medical Officer of the Haslingden Union.

RIMMER, J. F., M.B., Ch.B. Vict., Resident Assistant Medical Officer for the Workhouse, Birkenhead.

SAYRES, A. W. F., M.D. Brux., M.R.C.S., L.R.C.P., Public Vaccinator for the Woodford District of the West Ham Union.

WILKINS, T. HALFORD, M.R.C.S., L.R.C.P. Lond., Resident Surgical Officer to the Birmingham General Dispensary.

Marriages.

ADAIR—GODFREY.—August 8th, at the Parish Church, Redbourne, Lincolnshire, Edward William Mahaffy Adair, L.E.C.P.I., only son of the late Samuel Adair, Esq., H.M. Inspector of Schools in Ireland, to Elsie Blanche Beauchamp, fourth daughter of the Rev. George Godfrey, M.A., vicar of Redbourne.

BRUCE—DETTMER.—On August 12th, at All Saints' Church, Tufnell Park, London, James Thomson Bruce, youngest son of the late Robert Bruce, M.D., to Millinda Georgina, eldest daughter of George Frank Dettmer, of Highgate.

POLLARD—JOHNSON.—On August 8th, at All Saints' Church, Hyde, Fleet-Surgeon E. R. H. Pollard, Royal Navy, of B.N. Hospital, Hawlowline, Queenstown, to Mary Emma, only daughter of Captain W. J. Johnson, Royal Navy, of Hyde, I.W.

Deaths.

BOOTH.—On August 6th, at Church House, Chesterfield, Charles Booth, M.D., J.P., aged 73 years.

EATWELL.—On August 7th, at Church Road, Upper Norwood, in his 8th year, William Coverdale Beattie Eatwell, M.D., late Surgeon-Major Indian Medical Service.

HUNTER.—On August 11th, at his residence Pilbeach Gardens, Kensington, Brigade-Surgeon George Yates Hunter, M.R.C.S., Bombay Medical Service, ret. red, aged 68.

MEADOWS.—On August 2nd, at Lancaster Road, South Norwood, from the result of an accident, Brigade-Surgeon-Lieutenant-Colonel C. J. W. Meadows, H.M. Bengal Army, retired, aged 55 years.

RICHARDSON. On August 4th, at Melville Street, Edinburgh, Deputy-Inspector-General William Richardson, B.N. (retired).

WINTERBOTHAM.—On August 8th, at Arundel House, Bayshill, Cheltenham, Lauriston Winterbotham, M.R.C.S., aged 65 years.

NOTES ON A CASE OF HÆMATURIA FROM HEALTHY KIDNEYS. (?)

By T. MYLES, F.R.C.S.I.,

Vice-President Royal College of Surgeons, Ireland; Surgeon to the Richmond Hospital.

As the above-named subject has excited a good deal of interest lately, the details of a somewhat remarkable case of this description, which recently came under my notice, may not be without interest.

Miss L. A., æt. 26, by profession a nurse, was brought to me by my friend Dr. E. E. Lennon with the following history:—

Somewhere in September, 1898, she was operated on for hæmorrhoids and made an excellent recovery.

Shortly after this she began to suffer from recurrent attacks of pain in the middle line and on the left side of the abdomen, travelling down to the thigh. She had never an attack of acute severity, such as might fairly be called renal colic. The pain was of a dull aching character, and the young lady herself thought the pain was due to "indigestion"; in other words, that it was due to intestinal trouble. Vomiting occasionally occurred when pain was severe, but was infrequent. At a later stage of her illness the pain was practically constant, though never agonising. With this was hæmaturia and progressive emaciation and anæmia, the loss of weight in two months amounting to 28 lbs.

On examination, the patient is seen to be a girl of fine physique and large frame, though very pale and wasted.

On palpating the abdomen, both kidneys can easily be demonstrated to be movable, the left being particularly so. The right can be handled without pain, but pressure on the left, when displaced downwards and forwards, causes great suffering. The urine is almost pure blood. An analysis of it made by Dr. Earl shows that it contains no tubercle bacilli, and that when freed from blood by filtration, it is practically normal.

Examination of the bladder with the electric cystoscope was carried out under an anæsthetic on several occasions. At each examination blood could be easily seen to be ejected from the left ureter at regular intervals. The ejection of the blood produced an appearance, in the illuminated field of vision, comparable to that produced by the smoke of a cannon at the moment of explosion. This phenomenon I easily demonstrated to the gentlemen associated with me in the case: Sir Francis Cruise, Drs. Lennon, Joynt, Coady, and Elizabeth Tennant. Pressure on the left ureter from above downwards produced a copious flow of blood from the opening into the bladder.

After consultation, we decided that until rest in bed and administration of styptics had been tried, it would not be advisable to operate.

A flannel roller was placed round the body, the recumbent position was enforced, and the pharmacopœia, official and non-official, was exhausted in

efforts to check the bleeding. All, however, was in vain. Day after day the urine contained blood in large quantities; the treatment had no effect whatever.

A skiagram taken by my friend Dr. Lane Joynt gave a negative result.

After careful deliberation we decided to expose the left kidney in the loin, to examine both it and the ureter for stone or tumour, and to use the fluorescent screen on the kidney when outside the body, after the manner described by Mr. Hurry Fenwick. It was further resolved, that failing to find a stone or tumour to explain the bleeding, the kidney should be fixed in position, as there was a reasonable hope that a kink in its pedicle, due to its great mobility might be the cause of the bleeding.

Operation was performed on December 18th, Sir Francis Cruise, Drs. Lane Joynt and E. E. Lennon being present with me.

The usual incision below the last rib was made, and for the purpose of delivering the kidney through the wound, I utilised the suggestion of Edbohl, which I found to work admirably. For the benefit of those who are not familiar with the method, I may be permitted to explain it in a few words.

The incision being made in the lumbar region nearly vertically downwards, a pneumatic cushion of cylindrical shape being under the opposite ilio-costal space, the patient is rolled into the prone posture, so that the pillow, when distended, crosses the lower part of the abdomen. An assistant, now grasping the patient's feet, makes vigorous traction downwards, so that the patient rolls down on the pneumatic cushion. The increase in the intra-abdominal tension thus produced of itself delivers the kidney through the wound. The patient is then rolled back into the lateral posture and the operation continued.

The kidney on exposure seemed somewhat larger than usual, rather deeply congested, and of a distinctly lobulated type.

The room was darkened, the kidney wrapped in sterilised muslin and placed in front of the fluorescent screen, the latter being arranged in a box, with velvet hood, &c., so as to completely exclude all rays of light except those from the Crookes tube. A twelve-volt accumulator and a coil capable of giving an eight-inch spark was employed. The value of the apparatus was first tested by examining the hands of several of those present, and very clear shadows of bones were obtained.

On the kidney, however, the results were very disappointing. That organ itself cast a shadow as deep as bone, and even if a calculus had been present I more than doubt if it could have been recognised by this method. I do not know if Mr. Fenwick has successfully employed his method in the living patient, or whether his experiments have been entirely confined to the cadaver, but unless the new interruptor gives better results than those we obtained with the apparatus then in use, I question if the benefits to be got from the method compensate for the risks which are undoubtedly added to an operation already grave enough.

The screen having added nothing to our knowledge, I opened the pelvis of the ureter posteriorly, and introduced a long, flexible metal bougie, No. 4

size, and passed it into the bladder without any difficulty, and without encountering any stone or tumour. A child's sound was then introduced and the calices carefully examined. The opening having been sufficiently enlarged, I was able to get my finger into the pelvis and explore the calices thoroughly. The search proving fruitless, the exploring needle was thrust into the convexity of the kidney in a number of places, and a thorough and systematic examination of the kidney was made. None of these methods of search revealed either a stone or a tumour. A consultation was then held, and as a result of our deliberations, it was resolved to fix the kidney in position. This was effected by a method I have been practising for the last few years, and which has given me very satisfactory results. The wound in the pelvis of the ureter was closed by a number of fine catgut sutures, hardened in four per cent formalin solution, and subsequently sterilised by boiling for three minutes on two occasions with twenty-four hours' interval.

The perirenal fat was thoroughly removed both from the kidney surface and from the abdominal wall posteriorly. The fibrous tissue capsule of the kidney was then completely stripped from the deep surface of the kidney, as in a post-mortem examination of the organ, and a raw oozing surface was thus left exposed. The kidney was now carefully tucked back into place, taking care to push it well up into the hypochondrium. My assistant kept it in this position by pressure through the abdominal wall during the introduction of the sutures. The wound was closed completely by a double row of cat-gut sutures, no drainage of any kind being provided for. I determined to rely entirely on the sutures in the ureter, and strict asepsis to guard against leakage or its consequences. The usual sterilised dressings were applied, retained in position by strips of rubber plaster and a flannel roller.

The wound was not exposed till the fifteenth day after operation, when it was found to be completely healed, the superficial catgut sutures, as usual, coming away with the dressings.

So far as the operation was concerned it was a complete success, no rise of temperature, no pain, no diminution in the quantity of the urine after the third day, but the hæmaturia was as bad as ever. Evidently fixing the kidney had not controlled it, or even modified it in any way.

Naturally, this was a great disappointment to both patient and operator.

As the symptoms showed no signs of improvement, and as the anæmia was becoming profound, fearing that further delay might prove disastrous, it was resolved, after numerous consultations to remove the kidney completely, as no other course held out any prospect of saving the girl's life.

This second operation was performed on January 10th, 1899, twenty-three days after the exploratory and fixation operation, and proved extremely interesting.

It is not often we can expect to have an opportunity of testing by a second operation in a human being the result of an experimental method utilised in a former one; but now this rare opportunity was offered to us.

The second incision was made exactly along the line of the former one. The scar was found to be very firm and non-vascular. The kidney was easily found, but dislodged with the greatest difficulty. The raw surface of the kidney, stripped of its capsule, and the damaged ureter were simply imbedded in a dense mass of vascular fibrous tissue, which bled freely when separation was attempted. Considerable force was used, and every position tried for nearly an hour, before I succeeded in delivering the kidney through the wound. So difficult was the process, that at one

moment I almost resolved to close the wound in the loin and make an incision in the front, so as to secure the vessels before detaching the kidney from its bed. However, by patience and perseverance, the firmly-fixed kidney was at last detached and delivered through the wound. The vessels were then carefully cleaned and separated right up to the hilus, and each separate branch of both artery and vein was secured by catgut ligatures. In all, twenty-five ligatures were employed in this manner. No doubt this prolonged the operation, and is, in consequence, a disadvantage, but I did not care to use silk (for reasons familiar to every operator), by which the entire mass might have been tied off at once, nor did I care to trust such large vessels as the renal artery and vein to a single catgut ligature. By securing the small branches separately the risk of dangerous hæmorrhage was diminished, as the distensile force in such small vessels is very slight and thrombosis is very rapid. The ureter was divided between two ligatures, its contents being first carefully expressed. The stump was not cauterised nor treated in any way further. Each artery, after ligature, was held in a forceps, so that its mouth could be carefully watched to see that the hæmostasis was complete before letting it drop back into the abdomen.

The parietal wound, as before, was closed with a double row of catgut sutures, no drainage was employed. The patient made an excellent recovery, the urine gradually increased in quantity till from 11 ozs. on the day after operation it reached 42 ozs. on the sixteenth day. The temperature never rose above 99 degs. F., and on the sixth day the patient sat up in an armchair, and on the twenty-first day left the hospital for a drive in an open carriage. The dressings were not stirred till the nineteenth day after operation. The young lady is now in excellent health, has regained 12 lbs. in weight, and her colour is nearly normal. She has resumed her professional duties, and has quite recovered her usual buoyant spirits. Sir Francis Cruise has tested the percentage of urea in the urine on several occasions, and reports that it is now normal.

The kidney has been examined for me by Professor McWeeney, whose report I submit:—

"I.—NAKED EYE.—Kidney somewhat increased in size: consistency very firm and solid: capsule rather adherent, much thickened in places, especially near hilus: thickening due to increase of fibrous tissue and firm adherence to perinephric fat. On stripping off capsule several dark hæmorrhagic spots size of sixpenny piece on surface of kidney which was otherwise smooth and pale.

"On section; Cortex pale, by no means diminished in width. Pyramids also pale, otherwise normal.

"Pelvis: The mucous membrane red, thickened and pulpy, almost turgid-looking, covered with minute papilliform elevations and rugæ, which gave its interior a curiously rough appearance.

"Vessels: Normal save that the arteries seemed a little stiff, quill-like and gaping.

"Ureter: Normal so far as the point of operative division.

"II.—MICROSCOPIC.—Wedge-shaped pieces of the kidney with a superficial area of about 2 c.m. were embedded in celloidin and cut into sections 10 mm. in thickness which were mounted in serial order. They were stained in Ehrlich's hæmatoxylin, counterstained by Van Gieson's method and mounted in balsam. Study of these sections soon revealed the cause of the thickened and turgid appearance of the pelvic epithelium above noted. The sub-mucous tissue had undergone extensive mucoid change, the intercellular substance being swollen and hyaline and the numerous bundles of fibrous tissue and unstriped muscle fibre dissected out, so to speak, and widely separated

from each other. There were also very numerous spindle-shaped cells with long, very delicate processes gradually tapering and disappearing in the mucoid substratum. The thickness of this mucoid layer was measured and found to be '80 to '85 m.m.

"Above this layer came the transitional epithelium of the pelvis, which was in several layers and was raised up into irregular papillary or ridge-like prominences.

"Beneath it came a quantity of unstriped muscle-fibre arranged in bundles running parallel to the surface, beneath this some non-mucoid fibroid tissue was everywhere richly supplied with blood vessels which stood out more prominently than usual owing to the transparency of the intercellular substance. Here and there were patches where the vessels were enormously increased in number and although evidently capillaries, were of considerable dimensions. A projecting pillar of the pelvic mucous membrane which was present in one of the slides in transverse section, appeared as an area of mucoid tissue crammed with huge capillaries (0.4 m.m. in diameter) which were distended with red corpuscles. The margin consisted, of course, of the transitional epithelium.

"The hæmaturia for which the kidney was removed, receives its pathologico-anatomical explanation in the facts thus established. The case is one of diffuse myx-angiomatous change in the submucous tissue of the pelvis of the ureter.

"The kidney tissue itself showed very little abnormality. The epithelium was everywhere well preserved, even the striated border being distinctly visible. Here and there a few glomeruli were shrunken and the intra-capsular space was filled with transparent hyaline material with an affinity for acid fuchsin. The medium-sized arteries had their muscular coat distinctly hypertrophied. Signs of acute inflammation and micro-organisms were absent."

There are three points of great interest in this case to which I wish to draw attention.

First, the value of the fluorescent screen applied to the kidney outside the body. From the description given by Mr. Hurry Fenwick (to whose persistent advocacy of the electric cystoscope I gratefully acknowledge my indebtedness). I confess we were full of hope that the method would prove a useful adjunct to us in our anxiety to acquire definite and precise information. The result was most disappointing, not because it did not show us a stone that did not exist, but because of the extreme opacity of the kidney to the X-rays. A great deal of care had been taken to insure thorough exclusion of sunlight, by fitting special blinds, &c., to the windows of the room, the apparatus for holding the kidney close to the screen had been specially designed and made by my friend, Dr. R. Lane-Joynt; the efficiency of the whole was tested thoroughly before, during, and again after, the operation, so the discovery that the kidney outside the body was nearly as opaque as bone was a keen disappointment to us.

Moreover, it superimposed an additional anxiety on us, as anaesthesia was maintained for fully five minutes in total darkness.

Dr. Joynt and I have made repeated efforts to obtain satisfactory photos of renal calculi, both in the living subject and in the cadaver, and though occasionally we have succeeded in finding a slightly darker patch in the kidney shadow where a stone had either been placed experimentally or had been found in operation, it must not be forgotten that a sensitive plate is much more delicate than the human retina, and it is hardly fair to expect that the minute difference of opacity registered by a plate after fifteen or twenty minutes exposure, will be detected in-

stantaneously by the human eye. Though it is not fair to generalise from one particular case, still I am inclined to think that the suggested method hardly holds out sufficient hope of benefit to justify the time, labour, and additional anxiety involved in its employment.

The second point of interest is the method of fixing a floating kidney which I employed, and the opportunity the second operation gave us of testing its efficiency. I need not add anything to what I have already said on the subject, but I would venture to ask for a trial of the method which is so simple and, as far as I can judge, so efficient.

The last and most important point of all, the question—What caused the hæmorrhage? has been cleared up by the prolonged and careful researches of my gifted friend, Professor E. McWeeney.

Prior to the receipt of his report, though instinctively feeling that, to a certain extent, the result of the operation was the most potent argument that could be urged in its justification, I confess to having felt that the scientific basis from which the necessity for the operation could be logically deduced was wanting, and until such basis was discovered, the operation was merely a fortunate experiment. His report, however, has removed all such feelings of doubt, and has supplied the pathological justification for an operation of such gravity.

The condition described by him is, I think, unique so far as our present knowledge goes. Is it possible that the cases of so-called hæmaturia from healthy kidneys, which was apparently cured by incision and fixation, were cases of this kind. It is difficult to understand how cutting into the cortex of a kidney and fixing it in position can control or modify hæmorrhage due to a diseased condition of the pelvis of the ureter.

A CASE BEARING ON THE ETIOLOGY OF RICKETS.

By CHARLES ELGOOD, M.D.LOND,
Windsor.

AMONG the many theories that have been advanced to explain the origin of rickets, the most acceptance is undoubtedly given to that which refers the disease to improper feeding. Amply as this cause may account for the disease, as it occurs among the poor who frequent the London hospitals, it is when one meets with isolated cases occurring in districts where rickets is less common, that one is struck with the mystery that still surrounds the origin of this disease. As it is the duty of every medical practitioner to place on record cases which appear to militate against widely received opinions, no apology is offered for the following account of this somewhat unique family.

M. E. C., æt. 23, the daughter of a farm labourer, living with her parents in a cottage on a small farm, bore, in 1885, to a healthy young gamekeeper, an illegitimate male child, F. C. This boy, who was brought up entirely at the breast, has been several times under my observation, and though I carefully examined him on different occasions in childhood, he never presented any single symptom of rickets.

In 1886, M. E. C. married H. C., a farm labourer, aged 25, and for about a year lived with him under her father's roof. H. C., though dull and harmless, was a heavy-looking, boorish fellow, of rather slight build, standing 5 ft. 9 ins. high. He had coarse features, a sallow skin, and a head of a peculiarly conical shape owing to a marked projection in the neighbourhood of the posterior fontanelle. He had a receding forehead and chin. There was a thick crop of coarse, black hair. His chest was narrow

and covered with hair. His legs were straight, thin, and also very hairy. There was marked pes planus, with the part turned outwards. In short, there was little noteworthy about him beyond the fact that while his cranial peculiarities were the reverse of those that obtain in the subjects of rickets, his general appearance suggested to the most casual observer a lack of the average amount of intelligence. He was, however, not only able to get his living, but also to save a little money.

His father died some years back from pneumonia. His mother, who is alive and well, states that he was weakly from birth. He crawled on the floor till eighteen months, at which age he walked.

He had no trouble with his teeth and no fits. At eight he was considered by the doctor to be in "a decline."

From this union five children resulted. 1. H. C. C., was born in 1887, in the same cottage as F. C.

In September, 1887, the family moved to an old-fashioned farm-house originally built for people in better circumstances, situated about a mile from her previous residence, and 50 feet from the top of a hill rising gradually to 300 ft. above the sea level, on its south-eastern face. The house stands on the Wealden formation that is known as the Ashdown Sand, this bed being here represented in its entire thickness.

M. E. C. states that the symptoms, which subsequently became so familiar to her, were present in this child at the time of her changing houses. Of this, however, there is no evidence beyond the mother's statement, though, as will be seen, it is certain that the fifth child of this marriage showed signs of rickets at five months.

H. C. C. was suckled for the first three months of his life, and then fed mainly on condensed milk, though occasionally cow's milk was given instead. This child at three years of age presented a picture of advanced rickets such as is seldom seen beyond the wards of a hospital in a large town. He was emaciated to an extreme degree and quite helpless. He never walked at all. He died before he had reached the age of four of an attack of bronchitis.

2 J. H. C. (female), was born in 1888 in the same farm-house, and first walked when two-and-a-half years of age. At four-and-a-half she was a weak and wasting child with a large square head, pigeon breast, large swollen epiphyses, and marked genu valgum. She was fed at the breast for the first twelve months of her age, bread sop being given in addition.

3. W. R. C. (male) was born in 1890 in the same farm-house. At three years of age he was unable to walk, but sat and crawled in the manner usual to a rickety child. The fontanelle was unclosed. The epiphyses were large. He had not cut his back teeth. The tibiae were bending outwards. There was a pot-belly, bended ribs, and pigeon breast. He was fed in the same way as H. C. C.

4. H. J. C. (male) was born in 1891 in the same house. At two years of age he was just beginning to crawl and cross his legs, and the usual accompanying curvatures were plainly commencing in the radii and tibiae. The teeth were very backward. There was the rickety chest, pot belly, and in addition a marked dorso-lumbar kyphosis. The fontanelle was widely opened. He was fed in the same way as J. H. C.

5. E. J. C. (female), was born towards the end of 1892 in the same house. At five months she showed well marked bending of the ribs, though no other signs of the disease were present. This child never subsequently presented such a picture of rickets as did the other.

Unfortunately none of these children were seen by

me at birth, and there is no evidence as to the exact date of the commencement of the symptoms.

The eldest undoubtedly suffered the most severely, then the third, then the fourth, then the second, and then the fifth.

H. C. in June, 1893, committed suicide by hanging himself in a barn.

M. E. C. then went with her family to live in one of a long row of cottages situated about midway in point of distance between her two previous residences, and on a soil of similar formation to that on which her last house stood.

In 1896 she gave birth to another illegitimate child (female), the father being a strong, young labouring man well known to me. This child, M. C., now two and a-half years of age, is a sturdy, well-made little girl, and presents no sign of rickets. She ran well at 16 months, and began to cut her teeth at seven months. She was, like the others, fed at the breast for three months, and then given the bottle, which contained sometimes cow's-milk and sometimes condensed milk and water.

Shortly after this, M. E. C. married R. G., another labourer, and in 1898 gave birth to M. G., which child is now nine months of age.

M. G., though a pale, puny child, shows no sign of rickets. She is already suffering from an ailment supposed to be due to commencing dentition, though there are as yet no teeth discernible. She sits up well, and likes to "feel her feet." Her food has been the same as that of M. C.

This woman, though it is true that her answers do not always tally, is certain that the feeding of her different families has never varied very much. Her circumstances, too, have been apparently much the same all through. She asserts most positively that she was no poorer towards the close of her union with H. C. than she was at the commencement, though she was naturally more tied, having so many children unable to run alone. There can be no doubt that she was vastly better off in the matter of house accommodation during the period of her residence in the farm-house, which was large, dry, and airy, than she was subsequently when she lived in the small cottage. Her own health was excellent; she had never ailed anything.

The family that preceded her in the farm-house where the four younger rickety children were born, is well known to me, and all its members are well and strong.

Rickets is a disease by no means common in the neighbourhood, the climate of which (for England) is warm and dry. During several years of practice among the poor of the district only a few examples of the disease came across my notice, and I certainly did not see another case approaching in severity that of H. C. C.

Though the district is an entirely agricultural one, the poor as a rule give their children but little cow's milk, less indeed than do the poor of the towns in which I have lived, where milk is vended from door to door. The children are always suckled as long as possible, and, when the mother's supply fails, bread sop made with water is the usual substitute, to this is sometimes added condensed milk, and less often cow's milk finds its way into the mixture.

In this opinion that the children of the poor in rural districts are worse off in the matter of food than are those of the town-dwelling poor, I am supported by Dr. Palin, who, in an article on the "Etiology and Geographical Distribution of Rickets," writes: "The English town-bred rickety child and its mother are, as a rule, better fed than the healthy child and wife of the agricultural labourer." (1)

This case suggests itself as an instance of Mills's oft-quoted joint method of agreement and difference.

We are apparently presented with five instances of the presence of a phenomenon (viz., rickets), which have only in common the presence of one other circumstance (viz., the paternity of H. C.), and three instances of the absence of the phenomenon, which have only in common the absence of this circumstance; hence we would be inclined to conclude with von Rittershain (2) that there is a causal relation between the father's health and the disease in the children.

The case, however, does little more than serve as an illustration of the dangers inseparable from such a method of inquiry, or rather of its unfitness to deal with such complex problems as daily present themselves before us. It is obvious that even if this woman were to continue multiplying instances of this kind, we could never have the assurance that they agreed in the presence and absence of this single circumstance of H. C.'s paternity and nothing else. We have only to conceive it possible that some change in the mother's health may have occurred at or about the time of her first marriage, and so have affected her offspring, and our case against the father falls at once.

In view, however, of the order in which these children were affected as regards the severity of the disease, of the certain fact that, under very similar conditions, she bore and brought up children free from rickets on a diet very similar to that which she gave to the affected ones, and when we bear in mind that somewhat similar cases have been observed (3) we are forced to conclude that the usual theories that obtain in this country as to the etiology of the disease do not cover all the ground, and we are reminded that other theories of causation have been formulated at Vienna and Berlin.

May not those assumed factors in the production of rickets—bad food, and what is probably of much more importance, want of sunlight, operate with greater force in children who have inherited from either parent a constitution unduly prone to be affected by their influence? And may it not be that in crowded cities, where the immediate causes of the disease (whatever they may be) must certainly very largely prevail, a less amount of such an inherited susceptibility is required in order that the phenomena of the disease may be provoked? Thus the hereditary element in causation would be least patent to those observers who have the greatest facilities for studying the disease.

That the susceptibility to the disease is transmitted from parents to their offspring rather than the disease itself, is rendered still more probable by the experience of American physicians that rickets is more prone to attack the children of aliens than those of parents who are indigenous to the soil. Haven, of Boston (4), noted that the disease was most prevalent among the coloured population, and that the majority of white rachitics of foreign ancestry were born of parents who came from the South of Europe where the disease is by no means common—thus emigrants from the "Sunny South" would appear to transmit in more uncongenial climes the necessary susceptibility to their offspring.

Whether this be ceded or no, we are still far from being able to say why the assumed causes of rickets act with such signal partiality, and why it is that in other quarters of the globe such as New York, where the conditions under which the children live, cannot be so very dissimilar from those that obtain here, the disease is said to be so strikingly less frequent. THE TREATMENT OF FEVER FOLLOWING DELIVERY, WITH SPECIAL REFERENCE TO SERUM-THERAPY. (a)

By HERBERT SPENCER, M.D., F.R.C.P.,
Professor of Midwifery, University College, &c.

THIS subject includes the treatment of "puerperal fever (i.e., fever during the puerperium caused by microbial infection from without) and fever in the puerperium resembling puerperal fever. From this point of view fever in the puerperium could be arranged in four classes. The first class had been styled "one-day fever" and was characterised by a slight elevation of temperature, rarely exceeding 120 degs. F., about the third day, and usually cured by the administration of a mild aperient. The second class was due to complications which were not referable to the labour. Certain febrile diseases, such as influenza, scarlet fever, acute phthisis, and typhoid fever, closely resembled puerperal fever and deserved, therefore, special consideration. The diagnosis of influenza was sometimes used as a balm to the conscience of the practitioner who was not thorough in his application of antiseptics. Cases so diagnosed were often due to septic infection; nevertheless, he had seen undoubted cases during an epidemic and two of them terminated fatally, Septicæmia accompanied by a scarlatiniform eruption was often mistaken for scarlet fever. Acute phthisis closely resembled septic pneumonia and both forms of disease were equally unamenable to treatment. Typhoid fever presented great difficulties in diagnosis in cases in which the temperature rose in the early days of the puerperium. He had recently seen two cases; in both Widal's reaction gave positive results and as both terminated fatally the diagnosis was confirmed by the discovery of typhoid ulcers in the intestines. The third class of fever met with in the puerperium was due to infection from pre-existing lesions, such as ovarian and fibroid tumours, cancer, stone in the bladder, pyosalpinx, appendicitis, &c. The treatment of these cases consisted in the discovery and removal of the lesions during pregnancy. The fourth class was due to external infection and was what they understood by "puerperal fever." Recent bacteriology of puerperal fever showed that it might have its origin in a number of micro-organisms; important services in this department had been rendered by Döderlein, Strücnkman and Whitridge Williams. The latter in investigating twenty-six cases found streptococci in eight, staphylococci in three, colon bacilli in six, gonococci in two, anaerobic bacilli in four, diphtheritic bacilli in one, gas bacilli in one, and typhoid bacilli in one. Clinically, fatal puerperal fever was met with under three forms: acute septicæmia, which terminated fatally within a few days owing to the virulence of the poison; lymphatic septicæmia, the usual form, characterised by a rigor at the onset and septic peritonitis; and venous septicæmia, characterised by a succession of rigors and by septic phlebitis, and frequently by secondary deposits. Mild cases of puerperal fever were met with, as sapræmia—i.e., poisoning by the chemical products of micro-

(a) Abstract of Paper read before the British Medical Association at Portsmouth, 1899.

organisms—and local infection of the peritoneum, the cellular tissue, and the veins. Coming to the treatment of puerperal fever the most important element consisted in prophylaxis. It was important to avoid all unnecessary injury during labour by too frequent examinations or unnecessary forceps operations; while, on the other hand, labour should not be allowed to be unduly prolonged. Careful management of the third stage of labour was most important and it was particularly necessary to make sure that no placenta or membranes or clots were allowed to remain in the uterine cavity. Döderlein's experiments showed that in normal cases vaginal injections rather favoured the growth of micro-organisms than otherwise, but in every case the vulva should be washed with soap and water, then rinsed with water, and afterwards swabbed with 1 in 1,000 perchloride of mercury. The practitioner's hands, wrists, and forearms should be carefully cleansed in the same way. The ideal clothing was some white washable material. The question presented itself whether it was necessary for a medical man who had attended a case of puerperal fever to abstain from practice for a time. Mere abstention from practice he believed to be no safeguard, but thorough disinfection would immediately enable the practitioner to attend another lying-in woman with safety. As regarded the actual treatment of puerperal fever the first necessity was to make a thorough examination of the patient and of the uterus. An intra-uterine examination should be made in nearly every case, and in his experience cases apparently hopeless had been saved by the detection and removal of putrid portions of placenta or sloughing fibroid tumours. In making this examination he urged the importance of wearing rubber gloves which could be obtained so thin as to cause little or no interference with tactile sensation. Generally speaking, the uterus should be completely emptied by the finger; occasionally large blunt-ended forceps might be used, but the curette should never be employed after labour at full term. He had known the finger to be forced through the wall of the puerperal uterus, and the danger associated with the use of a sharp instrument like the curette must be much greater. After emptying the uterus the cavity should be irrigated once with a solution of iodine (one drachm of tincture of iodine to one pint) or a weak solution of perchloride of mercury or carbolic acid. The treatment of general septic peritonitis had been much discussed of late years. It had been proposed to open the peritoneum either by the abdomen or the vagina, and even to remove the uterus, and a number of cases successfully treated by both methods had been published. If the presence of fluid could undoubtedly be recognised then he thought the peritoneum should be opened, but he was not in favour of removal of the uterus except in cases of carcinoma, or of fibroid tumours which could not be enucleated. Methods of remotely influencing puerperal fever by the nuclein treatment (which aimed at producing an artificial leucocytosis), saline infusion into the celluloid tissue, and intravenous injection of antiseptics, were not of much value. The same must be said of drugs. Tonics and stimulants were useful, but in his opinion antipyretics should never be employed; cold-packing was the best method of reducing the temperature. The administration of food at regular intervals and in quantity as great as the patient could take was very important, and alcohol could be given in large quantities with benefit. Coming to the serum treatment he said that since its introduction by Marmorek in 1895 a very large number of cases had been treated by this method. Some observers regarded it as beneficial, others as useless or harmful, and, speaking generally, it might be said that those who had the greatest experience were the least impressed with its value. *A priori* it did not

appear to be a scientific treatment to administer, in a disease which was by no means generally associated with a streptococcus, an antitoxin produced by that organism. It might be useful in cases due to the streptococcus, which were the only cases for which Marmorek recommended it. Yet the committee of the American Gynaecological Society, which investigated the subject, showed that the mortality after its use was 33 per cent. It was doubtful if the natural mortality of the disease was greater than this. Some observers have reported that its use was not free from danger and had seen death apparently caused by it. Norris had seen it followed by erysipelas. The experience of the majority of observers was that the serum lowered the temperature, but exceptions even to this had been recorded. In judging of the effect of any treatment they must bear in mind the difficulty of prognosis in septic cases, the apparently hopeless sometimes recovering. The conclusions at which he had arrived were: (1) that as usually applied it had no scientific basis; (2) that it had not lowered the mortality of puerperal sepsis; (3) that it usually lowered the temperature and sometimes improved the general condition; and (4) that its use was not free from danger. It was possible that it might prove to be of value in pure streptococcal infection, but that the future must show.

URIC ACID AND THE CIRCULATION:

SOME NEW METHODS OF ESTIMATING ITS EFFECTS. (a)

By A. HAIG, M.D. Oxon., F.R.C.P. Lond.,

Physician to the Metropolitan Hospital, and to the Royal Hospital for Women and Children.

HIGH blood-pressure and defective capillary circulation are concomitant signs of the uric acid headache.

The headache is known to be due to uric acid, because all diet and drug treatment that relieves it diminishes the amount of this substance in the blood and urine. The headache is due to the effects of high blood-pressure on the cranial circulation.

If the explanation of these observed time relationships of signs and symptoms is, as I have suggested, that uric acid is the cause of defective capillary circulation and high blood-pressure, there ought not to be much difficulty in demonstrating the fact, and in this paper I shall bring forward some of the results obtained.

In the fourth and previous editions of "Uric Acid" I quoted a passage from Raynaud's writings, in which he says that in the disease which bears his name as much as thirty seconds may elapse before the colour returns in an area of skin rendered white by pressure; while in a piece of normal skin it will return in one or two seconds.

If Raynaud's disease is due to uric acid, as I have for years been suggesting, it follows that similar but less marked alterations in the rate of the capillary reflex (as I propose to call it) will be found corresponding with other and less marked alterations in the amount of uric acid in the blood, and this is what I now find to be the case.

After a good deal of experimentation I adopted an instrument that would give one a constant area of pressure, a known and measurable amount of pressure, and I measured the duration of the pressure, and the rate of the return of the colour, by means of a metronome beating half-seconds.

(a) Abstract of Paper read at the Portsmouth Meeting of the British Medical Association, August, 1899.

I further added to the test thus constituted an observation of the rate of disappearance of the "after-image," or fatigue image of the retina, as a measure of the good or bad capillary circulation in the retina. I also observed and recorded in curves either the size of the radial artery by Oliver's arteriometer, or the blood pressure by the Hill-Barnard sphygmometer, and the figures I now show were thus obtained.

A few months of daily observation proved that the whole of these things altered together; that slow capillary reflux went with high blood-pressure, or dilated radial artery, and with slow disappearance of the "after image" or *vice versa*.

Further, it showed that these results all followed exactly the well-known physiological fluctuations in the excretion of uric acid, the capillary reflux being slow in the morning and quick in the evening, and that these results corresponded with, and could be corroborated by the examination of the urine, the examination of the granules in the blood, and the relation of surface to deep temperatures as previously treated of in "Uric Acid."

In reference to drug action I soon found that, just as I had previously known that I could control the uric acid in the urine, the granules in the blood, and the relation of surface to deep temperature, so now I could control also with absolute certainty the capillary reflux, the retinal circulation and the blood pressure, either from day to day or from hour to hour.

That this could be done only by controlling the uric acid; but that if I failed to control only the uric acid, I also failed to control the circulation and its results.

In pathology, again, the tests tell the same tale, and it is now possible by observing the capillary reflux (C.R.) to say in less than half a minute whether the patient in front of you has a raised temperature (in which case the reflux will be 3-4 half-seconds), or on the other hand, has high blood-pressure or Bright's disease (in which case it will be 7-8 or 10 half-seconds) and a dose or two of salicylate of soda will in a few hours convert the former rate of reflux into the latter with a simultaneous increase of blood granules.

The figures I give illustrate physiology and the effects on it of diet, weather, salicylates, and fever; but it is only possible to show a very few of my results.

Anyone can duplicate the physiological results on their own persons, as in everyone living the ordinary life of this country the capillary reflux is at its lowest some time in the morning, and at its quickest some time in the evening; but if the normal uric acid curves are altered, the capillary curves will follow.

These tests are singly or combined indices of the amount of uric acid in the blood and urine, and this in the case of the capillary reflux can be estimated by anyone without instruments, and in ten seconds of time, though for more accurate work the simple instruments shown can be used.

Fever on the one hand, and Bright's disease on the other, are thus easily and quickly discriminated, and in the case of Bright's disease and diabetes attention is at once drawn to what I have long regarded as the central factor of these diseases, namely, defective capillary circulation and its consequence—defective combustion.

These results show that the observed relation between migraine with its slow pulse, high blood-pressure, and defective capillary circulation and an excess of uric acid in the blood and urine, is not an accidental coincidence, but a single instance of a general law.

Uric acid controls the capillary circulation of the body, and any accurate record of such capillary

circulation is thus an index of the quantity of uric acid in the blood and urine.

The Nursing Problem.

NURSES OF THE LATEST FASHION.
A.D. 1899.

PROFESSIONAL EXPERIENCES IN SHORT STORIES.

By FREDERICK JAMES GANT, F.R.C.S.,
Consulting Surgeon to the Royal Free Hospital.

IV.—THE INFANTICIDE NURSE.

In one of our metropolitan hospitals, famed for the nurses produced under its system of training, two sisters by birth had entered at the same time as probationers; at the end of two years to advance to the higher grade of full nurse or sister; when completely qualified, either to remain as ward sister, or to enter some nursing institution and practice her calling as a "certificated" nurse, or she may hold only a hospital certificate. It would be optional for a nurse, thus qualified and guaranteed by either certificate, to practice as a private nurse on her own account. When engaged in private nursing, something might here be said on behalf of the public welfare, in favour of a nurse who is *still* attached to an institution, rather than one who migrates in search of a situation, bearing with her the certificate she had earned, sometime since, and without any continued credential of what she is, as when engaged from an institution of recognised character. A nurse's own character may have changed since the day of her certificate, and is not followed up when she continues her calling—as private nurse—unattached.

The two sisters I have in view were separated by fifteen months only in point of age, but they differed in nature's gifts of mental endowments, moral nature, and bodily temperament. As they grew to womanhood latent inborn differences of character, nurtured in the earth of bodily temperament, began to assert themselves, declaring the duality of the sisters, Blanche, ardent, truthful, trustful, true, self-sacrificing; Beatrice, ardent, fallacious, furtive, fickle, self-loving, self-seeking, they yet clung together with the tenacity of almost twin-kinship; and thus it was Blanche and Beatrice entered, at the same time, the same hospital as (nurse) probationers.

A nurse is like some musical instrument, whose notes are touched in harmony by an invisible hand with the fingers of suffering humanity. And she possesses no less the qualities in common with other good women, but which are not more specially impersonated in her womanhood. *Purity* adorns her face with its own expression of loveliness, lit up with the light of *truthfulness*, which her felt sacred vocation imparts; and which are breathed in all her conversation and womanly gestures; *trustful* also is she in the confidential relationships of her office, even as she herself is faithful in the depths of a heart true to her calling. *Self-sacrifice*—in ever doing good to others, a most essential, and the crowning qualification of nurse-womanhood, is, indeed, quite a natural gift, educated, however, by training, for the relief of suffering humanity, at the cost of self, in ease, comfort, or even health.

I am certain that this is no ideal picture of nursing womanhood, toned down, however, in different personal representatives. Nurse Blanche approached nearly to the ideal in the course of her natural development and "training." In another ward Beatrice is on duty, so like a twin sister, and fashioned from childhood by the same domestic and social circumstances up to the time of entering the hospital as a nurse-probationer—will she develop her sister's beauteous qualities of young womanhood, or not? She is quite as devoted to her work, sharing equally the enthusiasm of Blanche's nature. But her ardour is not toned by sympathy, nor freighted and tempered with those other qualities of

character which would constitute her a model nurse. She lacks her sister's gentleness, loving kindness, and patience in her attendance on the sick; and with a turbulent temper, unable to govern herself, she speaks and acts with a domineering firmness of purpose which cannot smooth the pillow and ease the bed of sleepless suffering.

Beatrice indeed begins to feel her own unfitness for the duties of hospital nurse, and she realises a jealous comparison of Blanche's perfection. The unfit sister will never be able to honestly earn her living as a private nurse on her own account; and with her known defects of character, even now that she has finished her course of training, no institution would enter or retain her name on its list of "certificated" nurses. Sister Blanche has become a model member of that order of women.

Both sisters have quitted the hospital; the one, to the great regret of the matron, and bearing with her the high esteem of all her fellow-workers, bound together by that peculiar tie of affection which unites a body of nurses who have to share all the uncertainties of a calling subject to many chances and vicissitudes; a calling which cannot secure the permanency of engagement which may belong to another class of women, in domestic service, or in houses of business. A nurse at 50 years of age, who has done honour to her calling, in many engagements, is as much a floating, drifting woman as one of 25 years—launched on the vast ocean of human life.

But, with Blanche and Beatrice, their probable career would differ as widely as their characters. Blanche was readily recommended by her institution from one patient's case to another's, but having become a private nurse on her own account, she enjoyed a more lucrative practice; while her sister, having failed to become connected with any Institution, she floundered with the hope of finding some situation as a nurse, uncertificated; but in vain she offered herself; nor could she get a private testimonial from patient or doctor. Thus it was that Beatrice bethought herself of an expedient, in her dire necessity, to earn her living. Her flourishing sister, surely needed not her certificate, and could spare the document without loss to herself. The uncertificated sister stole her sister's certificate; or rather, she forged one in her sister's name, and by this means was enabled to obtain employment as Nurse, bearing with her the credential of a certificate.

But, on one occasion, in answer to an advertisement it chanced—if by chance it was—that both the sisters offered themselves, as nurse, for attendance in the same case. In fact, no sooner had Nurse Beatrice with the forged certificate, entered the house and had been engaged, subject to hearing from the lady definitely after seeing other applicants who might present themselves, than her sister Blanche called for a like purpose.

This might have seemed only a certain coincidence to the patient, but it flashed across the mind of the sister as a possibility, a probability, she knowing something of the erring antecedents of her poor sister, and she immediately suspected Beatrice.

Those who know anything of the love-bond between two sisters, in many such instances of blood-relationship, will understand also the heart aching which *she* would feel, who to claim her own right must sacrifice her sister, by fastening upon the beloved second self the personal wrong she has done—and the crime of forgery! Better a thousand times to bear the heart-ache than rend two hearts asunder, killing both. Yet, stimulated by that curiosity which prompts or compels inquiry, Blanche sought her sister's present address, and the two met, face to face. In the confessional of that interview, love acknowledged the truth, a full and unreserved confession, which penitence in the mouth of halting, faltering fear would never have told. "Not a word more, dearest Beatrice," said Blanche, sitting close, with both her hands clasping the right hand of the forger, her tears falling as if to wash away the iniquity from the instrument which had done the deed, pardoned by a sister's love on earth and by trust in Heaven.

The beginning of evil-doing is like water spilt upon the ground, it cannot be gathered up again. So it was

with Beatrice. She would not, could not, again use the guilt stained certificate which personated her sister Blanche. Thus her "private nursing" fell off, as she could no longer pass for what she was not; and she felt that to style herself nurse or nurse-attendant, without any qualifying credential, would be no less a falsehood—differing only in degree from holding a false certificate.

But the demon of evil still pursued her; although she had wrenched herself from his first grasp, he caught her again to make her his instrument in another form. The arguments seemed most plausible. She must earn her living, whoever might pay her wages, or starve! On a dark December day, when the wind whistled around, and the flakes of snow fell fast with a dull thud on the window panes of a little bed-room in a retired suburban house, a young lady lay on a couch in that room, which, with the adjoining sitting room had been hired on her behalf by a gentleman, who then left the house. The young lady bore, in her manner and conversation with the landlady, the evidence of birth and culture; while her pensive reticence and sadness of face gave expression to a singular beauty, and won sympathy for one who seemed to need no special sympathy.

Accompanying the young lady-lodger, there was another young lady; whether a relative, friend, or companion to the high-born invalid, no one could have told. On the third day, screams in the bed-room were heard all over the little house; and soon after these signals of suffering, fainter cries followed. The landlady alarmed, hastened to the room, but the door was locked; all was still, save now and then the fainter cries, no more than as crackling sparks of a fire, which at last died out. The young lady-friend, within an hour, quitted the house, bearing a bundle of clothes, a night dress, &c., for the "wash," at a residence of which she gave the landlady the address. It might have seemed strange to have the washing done elsewhere; and indeed the young lady, in delicate health, was amply provided with dress of every kind. When the landlady visited her in the bedroom, she gave, in explanation of her cries, the fact that she had suffered from "flooding"—to which she was subject. In a few days she felt that she would be quite well; and as the rooms did not suit her she must leave, paying, of course, the month's rent, for which time the rooms had been taken.

On the day of the young lady-friend's departure, the "husband" called to fetch his wife away. He had not called during the ten days of her absence, as he had received personal information from their young friend of his wife's health. He thanked the landlady for all her kindness and personal attention to the invalid, and gave her a present of a £5 note, in addition to paying the month's rent.

Thus, the mysterious lodger came, and went away. But an Unseen eye of justice, softened by mercy, had watched the destiny of that "bundle of clothes for the wash." It was traced to the young-lady friend's domicile. A coroner's inquest held, for some mysterious reason, compelled the attendance of *that* young lady, and somehow, the clothes which had not yet been washed, were produced. Within the bundle was concealed the remains of a newly-born child; a deep furrow around the neck betokened strangulation—as with a circle of strong string, or small cord, which still lay in the bundle.

The inquest was adjourned for a post-mortem examination of the infant; the lungs were found to have been fully inflated, and floated in water; an evidence conclusive in the absence of gas generated by decomposition—that the infant was born alive. Hence the infant's cries ere it was strangled to death. The death had now assumed the character of murder, and as the bundle containing the little body and cord was found in the possession of the young lady-friend, and as she was the only person present at the birth of the infant whose neck bore the cord mark of strangulation, the said young lady was clearly identified as the murderess. She, the witness summoned at the inquest, was none other than Nurse Beatrice.

The coroner's jury returned a verdict of murder, and the case went for trial at the Criminal Sessions. A true bill returned by the grand jury seemed to give the

prisoner no chance of escape. But, under the direction of the learned, and, certainly, merciful judge, the jury on the trial returned a verdict of "concealment of birth."

But the moral of the story is this: Nurse—with lately the forged certificate, and now guilty of murder, underwent a short imprisonment, and then resumed her private nursing, with liberty to again prove that her way of killing is no murder. And the poor bewildered mother, driven to extremity when pregnant with an illegitimate child, ready to risk her own life in the destruction of her offspring, as an accessory to the crime; she escapes scot free from the hand of justice.

What human judgment can rightly apprise the relative guilt of the mother and the confederate nurse in this crime of murder? The one, in her extremity, "to hide her womanly shame from every eye, and give repentance to her lover, if herself to die," the other, in her extremity, to save herself, possibly, from the spectre of starvation, by crime. The Unseen eye alone can adjudicate.

Clinical Records.

TWO CASES OF THE SUCCESSFUL REMOVAL OF A TUMOUR OF THE SUPRA-RENAL CAPSULE.

By MAYO ROBSON, F.R.C.S.,

Hunterian Professor of Surgery in the Royal College of Surgeons of England; Senior Surgeon to the Leeds General Infirmary.

At the Annual Congress of the British Medical Association at Portsmouth this month, the author related two cases in which he had successfully removed a tumour of the supra-renal capsule. One in a woman, *æt.* 47, operated in 1891, who died of recurrence of sarcoma exhaustion several months after the operation.

Case II. was that of a woman, *æt.* 62, on whom he operated in 1897, and who is still living and well. The tumour removed having been a struma lipomatosa supra-renal as described by Virchow. In the former case the supra-renal growth was so firmly fixed to the top of the kidney that that organ had to be removed as well, but in the latter case only a wedge-shaped piece from the top of the kidney was removed with the tumour. In the patient who is still living the removal of the tumour had not been followed by any pathological phenomena.

He also related a third operation, in which his colleague, Mr. Ward, had removed a sarcoma of the adrenal from a child, *æt.* 12 months. The child died from shock within a few hours.

The author gave a table of nine cases, of which five had recovered and four died. He believed these to represent the whole operative surgery of the supra-renal capsule.

He said that he thought the true secret of success lay in operating at an early stage of the growth as in his second case.

After describing the operation cases, Mr. Mayo Robson mentioned a case of sarcoma of the supra-renal capsule which he had observed throughout its whole course in 1875, and from this case and others that he had seen he drew attention to the following symptoms.

(a) Shoulder-tip pain, this was so well marked in all the three cases that he thought it could not have been a mere coincidence, but was probably dependent on the disease. It might be explained by the fact of small branches of the phrenic nerve passing to the semilunar ganglia,

(b) Pain radiating from the tumour across the abdomen and to the back, not along the genito-crural nerve.

(c) Marked loss of flesh.

(d) Nervous depression with loss of strength.

(e) Digestive disturbance, flatulence, and vomiting.

(f) Presence of a tumour beneath the costal margin, right or left, at first movable with respiration, but soon becoming fixed. It could be felt in the costo-vertebral angle posteriorly, and could be pushed forward into the hollow of the palpating hand in front of the abdomen.

(g) Absence of urinary and of gall-bladder symptoms.

SOFT SOAP TREATMENT OF TUBERCULOUS AFFECTIONS.

For the last thirteen years Prof. Albert Hoffa, of Wurtzburg, has been using soft soap inunction in all forms of local tuberculous affection, and in the *Munch. Med., Wochsch.*, 9, 99, he reports on his experience. The soft soap inunction, it should be said, is always used as an adjunct to the ordinary general treatment. The case treated consisted of spondylitis tuberculosis of the hip, knees, foot and elbow, as well as of the glands and skin, and he claims that the effect has been good. It is said to be wonderful to observe the difference in the results obtained between cases treated with and those without the soap inunction. Under the influence of the soft soap treatment the general condition of the patient and the appetite rapidly improve, the tuberculous joint swellings rapidly become smaller, fistulae close up quickly and glandular swellings subside. Wonderful results are seen, especially in the multiple tuberculous diseases of bones and joints, and children already much reduced. As regards the selection of the preparation of soap it is to be remarked, according to the author the only kind suitable is the *sapo kalin-venali* kept in the shops, which is prepared from linseed oil and crude caustic potash without spirits of wine, and which always contains a small excess of caustic potash and its carbonate. The author rubs in 25 to 40 grms. of this soap two or three times a week, and lets it lie on half an hour, at the end of which time it is washed off with a sponge and warm water.

As regards the mode of action of the soap the author confirms the ruling view, among others, that of Kollmann, that under the influence of the soap treatment the injurious lactic acid circulating in the system becomes neutralised, and that the alkalinity of the blood is increased. The increase in the alkalinescence caused increased tissue change, and this acts favourably on the general condition and especially on the affected parts.

THE THYROID AS AN ANTIDOTAL ORGAN.

At the Society for Innere Medizin Dr. F. Blum, Frankfort a/M., gave his views and reported on his experiments in determining the true function of the thyroid body. Like most others he denies that it is in any way a gland, as it possesses no secreting organs. In his opinion investigators have been misled in their views, and have wrongly interpreted facts observed by them. The course of disease after removal of the thyroid has been the cause of much discussion. The disease varies very much, and oscillates principally between severe attacks and free intervals. If, when an animal is passing through an active period thyroid preparations are given

and a free interval follows, the belief obtained that the preparation was the cause of the free interval, whilst in reality the freedom from active evidence of disease would have taken place as a matter of course. Dr. Blum extirpated the thyroid from 100 dogs, 96 of which became diseased, whilst four remained healthy. From this it may be concluded that the thyroid body is a vital organ, but that occasionally reserve powers are retained in the body that compensate for its loss, four of the dogs remaining healthy. Of the 96 animals that became diseased not one could be kept alive by feeding with thyroid in any of its preparations.

According to these facts, therefore, the thyroid is a mere gland, but that it attacks something circulating in the system and renders it harmless. This harmful substance is a toxalbumin saturated with iodine. The iodothyrene is not profound in the thyroid. Iodine was found in the thyroids of all the animals. When potassium iodide was given an increase in the organic iodine combination took place. The thyroid holds its iodine very fast, as experiments had shown. The chief purpose of the thyroid was the imprisoning of the poisonous combination, after its removal serious disturbances are set up which principally proceed from the central nervous system. For, according to Nissl the ganglion cells show constant changes, swelling of the cells from increase of the protoplasm and disappearance of the granules.

VIENNA, August 19th, 1899.

TEST FOR MERCURY VAPOUR.

At the meeting of Physical Medicine Kunkel drew attention to the imperfection of the present test for mercury vapour in the atmosphere, which was performed with gold-leaf, but owing to the condensation of watery vapour on the gold surface a constant error arises of a variable quantity. In addition to this error, another deviation from the truth is found in the mercury that is taken up by the nitric acid present and not deposited on the leaf.

The most recent method is to pass the suspected air over crystals of iodine when the mercury combines with the iodine to form the mercuric iodide. The *modus operandi* is to take a dry glass tube from two to three millimetres wide, into which are put a few fine crystals of iodine. Over these crystals fifty to a hundred litres of the suspected air is slowly conducted. The reaction in this test is so delicate that the one-hundredth of a milligramme may be detected by a glance at the colour. The mercury iodine tube is now washed out with a few drops of a solution of the iodide of potassium, and then filtered, which removes the iodine crystals completely. With the object of combining all the iodine vapour, hydrate of soda is added till all colour disappear. A stream of H_2S is then passed through the substance and mercuric sulphide formed, which may then be estimated by the colometric method. It should always be carefully borne in mind that the mercuric vapour to be examined should not be passed too quickly through the absorption tube, or a slight error might arise.

MYOTONIA CONGENITA.

Muller demonstrated a boy, suffering from a typical

form of this disease, which is more familiarly known as Thomsen's disease. It is a congenital anomaly of the muscles, particularly the transverse striped muscle, which becomes stiff after a voluntary effort and remains in a state of contraction for some time before the will can relax it again or bring it back to a position of rest. In this case the duration of the stiffness lasts a few seconds, and occurred in light efforts as well as severe. All the voluntary muscles were affected as well as the tongue. The pharynx, larynx, œsophagus, and respiratory apparatus were unaffected.

According to Erb, this disease yielded to the reaction of electricity and mechanical friction, which might be tried in this case.

ALCOHOL AS A NUTRIENT.

The question still exists, "What influence has alcohol on the metabolism?" How does it affect the nutrition or changes in the respiratory system?

From the various examinations it is affirmed that it acts on the albumen and checks the metamorphosis. According to the experiments of Riess, von Jaksch, and Strassmann, the elimination of nitrogen is reduced by the use of alcohol; while Romeyn Keller, Ström, Stammreich, Miura, and Schmidt affirm the opposite, and do not think it a preserver of albumen. Neumann assured the Gesellschaft that the experiments on himself did not sustain the latter arguments, although the believers were numerically greater.

The whole time of experimenting was 35 days, commencing after 70 days abstinence from all alcoholic drink. This period he divides into six parts as follows:—

The first part consists of five days, in which was given 76 grammes of albuminoids, 224 grammes carbohydrates, and 156 grammes of fat, which would be equal to 2,681 calories of nitrogen equivalents.

The second part consisted of four days in which the fat was reduced by 77 grammes, bringing the caloric force down to 1,959, but this was found to be insufficient, as the nitrogen supplied was too low.

The third part comprised ten days in which the 77 grammes of fat were supplemented by an isodynamic, equivalent of absolute alcohol being 100 grammes. The nutrition of the body was now found to be sufficient, probably from the activity of the alcohol. This addition brought the caloric force up to 2,677 again, giving a similar nitrogen equivalent as at first.

The fourth part embraced six days of the whole period in which were given the original amount of fat (156 grammes) with the 100 grammes of alcohol continued as in the preceding part, which would now give a caloric force of 3,401. The diet was now found to be excessive, the elimination of nitrogen not being proportionate to the intake, or on account of the alcohol is reduced.

The fifth part comprehended four days in which both alcohol and the 77 grammes of fat were withdrawn, reducing the caloric force again to 1,959. The diet was again insufficient, as the loss of nitrogen proved.

Finally, the sixth part was continued for six days, in which the original diet was resumed with a caloric force of 2,681. The equivalent expenditure of nitrogen was now re-established as in the first part.

In a tabular demonstration of his experiments, Neumann pointed out that in the second and fifth part of the experiment the nitrogen intake was 12 to 16; elimination 13 to 79. During the third part he found that

between the fifth and tenth day the nitrogen was equivalent, and must therefore be accepted as sufficient. In the fourth part the nitrogenous intake was 12 to 19, while the elimination was 10 to 84. It is to be noted that the first day of the third part of the experiment the nitrogen elimination was increased. This Neumann explained, was probably due to the long prior abstinence from alcohol and the sudden administration of large quantities of alcohol, which would act at first on the protoplasm as a poison, and thus increase the destruction of the albumenoid material. The figures in this case were 12 to 16 as intake, and 15 to 21 as elimination. As soon, however, as the system became acquainted with the toxic effects the disturbance subsided, and the alcohol afterwards acted as a nutrient or as the fat did before the alcohol was substituted. This opinion is further supported by the facts of the fifth part of the experiment, when both fat and alcohol were withdrawn, which shows that the alcohol must have supplied the deficiency of the fat. The fourth part is unassailable as a proof that alcohol retains the integrity of the albuminoid element.

Neuman finds that his first four days of the fourth part agrees with those of Miura and Schmidt, who did not continue their experiments longer. He concluded his remarks with an expression of his own conviction that the facts proved that alcohol was a dietetic, but he thought the toxic effect should be reduced to the minimum.

THIRD INTERNATIONAL CONGRESS OF GYNÆCOLOGY AND OBSTETRICS.

[FROM OUR OWN CORRESPONDENT.]

AMSTERDAM, August 8th-12th, 1899.

THE Congress was inaugurated in the Hall of the University on August 8th. The President of the Congress, Professor Hector Treub, of Amsterdam, occupied the chair; whilst on the platform were the Burgomaster of Amsterdam, the Minister of Public Instruction, and the members of the Permanent Congress. After the introductory address by the President, and the report of the general secretary, Dr. Mendes de Leon, the names of the honorary presidents nominated by the committee were submitted to the meeting and unanimously endorsed. The delegates of foreign Governments and scientific societies addressed the meeting, viz., Dr. Engelmann for the United States of America; Dr. Jacobs for Belgium; Dr. Robert Barnes, Mr. Bowreman Jessett and Dr. Heywood Smith, on behalf of England; Dr. Fargas, of Barcelona, presented an invitation to the Congress from the Mayor and municipality of Barcelona, to meet in that city in 1902. Dr. Jonnesco, of Bucharest, presented a similar invitation on behalf of Roumania; Dr. Stockvis spoke on behalf of the Dutch Association for the Advancement of Medicine, Dr. Westermarck for Sweden, Dr. Schonberg for Norway, Dr. de Rein for Russia, M. Pinard for France, and Dr. Pasquale for Italy.

In the evening two receptions were held; first, by the Burgomaster, at the Town Hall, and then by Prof. Treub, Dr. Mendes de Leon and Mesdames Treub and Mendes de Leon at the Maison Conturier. To the latter, ladies were invited, and a very successful gathering took place, enlivened by music and dancing.

WEDNESDAY, AUGUST 9TH.

The following papers were read:—

M. Delageniere (Le Mans), On the Shortening of the Round and Broad Ligaments in Retroversion of the Uterus. Discussion by Messrs. Jacobs, Reed, Goldpohn, Vineberg, and W. Alexander.

M. Doyen (Paris), The Treatment of Spontaneous and Post-operative Gynæcological Fistulae.

Dr. La Place (Philadelphia), Demonstration of a Forceps for Intestinal Anastomosis.

M. Reynier (Paris), Total Abdominal Hysterectomy for Cancer of the Uterus. Discussion by Messrs. Doyen, Jacobs, Jonnesco, Bowreman Jessett, Pestalozza, and Jauvrin.

M. Heinrichius (Helsingfors), On the Clinical Importance of Retrodeviations of the Uterus.

Dr. Ziegenspeck (Munich), On Operations for Stenosis.

Dr. Jonnesco (Bucharest), Total Abdominal Castration for Adnexial Affections, whether Septic or not. Discussion by Messrs. La Torre, Reynier, Stratz, and Hartmann.

Dr. Palmer Dudley (New York), Intra-Uterine Implantation of the Ovary.

At the afternoon Session M. Richelot, of Paris, introduced a discussion on the Relative Value of Antisepsis and Improvements in the Technique, in the results of Operative Gynæcology. In this discussion the following took part:—Messrs. William Alexander (Liverpool), Robert Bell (Glasgow), Hartmann (Paris), Jonnesco (Bucharest), Stratz (La Haye), Doyen (Paris), De Rein (Kieff), and Heywood Smith (London).

We append short abstracts of some of these communications.

THURSDAY, AUGUST 10TH.

Mlle Catharine v. Tusschenbroek (Amsterdam), Ovarian Pregnancy. Discussion by Messrs. Meyer and Pinard.

Dr. Davis Edwards (Philadelphia), The Management of Labour in Abnormal Pelves.

Dr. F. La Torre (Rome), The Nomenclature of the Oblique Diameters of the Pelves, from the point of view of International Obstetrics. Discussion by Messrs. Davis, Treub, Rapin, Bar, and Pinard.

Dr. F. La Torre: The Morphological Classification of Contracted Pelves. During the discussion on this paper it was suggested that an International Commission should be appointed to revise obstetrical nomenclature; M. Pinard, the President of the Section, nominated for this purpose the following gentlemen:—Prof. Treub, President; Messrs. Bar, La Torre, Rapin, Queirel, de Rein, Davis Edwards, Simpson, and Freund. The commission at once elected M. Paul Bar as secretary, and it was hoped that the report of the Commission would be presented at the Obstetrical Section of the Paris Congress in 1900.

M. A. Favre (Chaux-le-Fonds), Labour and Nephritis.

M. Cosentino (Cattania), Demonstrations of Sections of the Cadaver.

M. F. Villar (Bordeaux), On Appendicitis in Women.

Dr. Oscar Beuttner (Geneva), (a) Experimental Researches on Castration-Atrophy; (b) the Use of Salipyrine in Gynæcology; (c) Vomiting of Coffee-ground Coloured Material after Anæsthesia in Gynæcological and Obstetrical cases where instrumental or operative interference has been resorted to.

M. E. Doumer (Lille), On the Use of Currents of High Frequency in Gynæcology.

M. J. L. Faure (Paris), Total Abdominal Hysterectomy in Suppurations of the Adnexa.

M. H. Duret (Lille), Colpohysterectomy in the Treatment of Irreducible Inversion of the Uterus. Discussion by Messrs. Dudley and Gutierrez.

Dr. A. Goldspohn (Chicago), Indications, Technique, and Results of the Alexander Operation in Aseptic Adherent Retroversions of the Uterus, when Combined with Inguinal Coliotomy to Liberate the Organs and to Resect or Remove the Adnexa when necessary.

At the afternoon session a discussion was held on "The Influence of Position on the Shape and Dimensions of the Pelvis." This was opened by Messrs. Bué, Pinzani, and La Torre, and continued by Messrs. Kouwer, Nyhoff, Pestalozza, Ziegenspeck, Engelmann, and Pinard.

A series of preparations was exhibited to illustrate Mlle. v. Tusschenbroek's paper on Ovarian Pregnancy

DEMONSTRATIONS.

M. Doyen (Paris), gave two demonstrations of various operative procedures by means of the cinematographe. The first demonstration, on August 9th, had reference to general surgery. By this means were represented amputation of the thigh, excision of the knee-joint, removal of the thyroid, excision of cerebral tumour, &c. The second demonstration, on August 11th, illustrated M. Doyen's methods of vaginal and abdominal hysterectomy.

M. Keiffer (Brussels), showed a number of microscopical sections illustrating the following subjects:—1, the structure of the normal uterus and its vessels; 2, the development of the ovum and the corpus luteum; 3, the development of fibro-myomata; 4, The uterine mucosa in successive phases of menstruation.

FRIDAY, AUGUST 11TH.

The following papers were read:—

M. Delageniere (Le Mans), Total Hysterectomy in Cases of Fibromata Complicated by Albuminuria.

M. Gouilloud (Lyons), Force Pressure of the Uterine Arteries in Fibromata.

Mr. Bowreman Jessett (London), On the Treatment of Uterine Myoma.

Dr. Robert Bell (Glasgow), Medical Treatment of Fibromyoma and Ovarian Disease, and of Incipient Carcinoma of the Cervix.

M. Woskresensky (Kieff), The Principles of Treatment of Uterine Myoma.

M. d'Hotman de Villiers (Paris), A Case of Total Abdomino-Vaginal Hysterectomy for a Large Fibroma.

Mr. Doleris (Paris), The Treatment of Fibromata with Pregnancy.

M. Duret (Lille), Certain Special Operative Procedures in the Treatment of Fibromata.

M. Gutierrez (Madrid), The Surgical Treatment of Myomata.

M. Fargas (Barcelona), The Surgical Treatment of Myomata.

Dr. Treub (Amsterdam), Statistics of his Results of Operations for Fibroma during the last three years.

M. Schmeltz (Nice), A New Procedure for Abdominal Hysterectomy.

In the afternoon the question for discussion was "The Surgical Treatment of Fibro-Myomata." The discussion was opened by M. Doyen, of Paris, and the following members of the Congress took part in it:—Messrs. Delageniere, Reynier, Tuholske, Alexander, Carstens, Bell, Jacobs, La Torre, Giles, Engström, Galvani, Tournay, Jonnesco, d'Hotman de Villiers, Jessett, Villar, Heywood Smith, Heinricius, Pestalozza, Sinclair, Gordon, and Jaybe.

SATURDAY, AUGUST 11TH.

The following papers were read:—

Prof. Treub (Amsterdam), Antisepsis in Symphysiotomy and Caesarian Section.

M. Chaleise-Vivie (Bordeaux), the Innocuity of Anaplastic Amputation of the Cervix in relation to Pregnancy and Labour.

M. Rapin (Lausanne), on Insufflation of Air into the Uterus as a means of Prevention of Fœtal Asphyxia.

M. La Torre (Rome), the Classification of the Positions of the Fœtus.

M. Queirel (Marseilles), Urology of Pregnancy and the Puerperal State.

Dr. Van der Velde (Amsterdam), the Elimination of Methylene Blue in Pregnancy.

M. J. L. Faure (Paris), Total Abdominal Hysterectomy for Cancer of the Uterus.

M. H. Hartmann (Paris), on the Operative Treatment of Salpingitis.

M. Laroynne (Lyons), the Treatment of Cystocele by a New Process of Cysto-hysteropexy.

Dr. Jonnesco (Bucharest), a New Method of Sewing up the Abdominal Wall without Varied Sutures.

M. H. Brodier (Paris), on Periodic Intermenstrual Pain.

At the afternoon session the discussion on "The Relative indications of Caesarian Section, Symphysiotomy, Craniotomy and premature Induction of Labour was introduced by Messrs. Pinard, and Pestalozza; and con-

tinued by Messrs. Arthur Giles, L. Meyer, Cosomilas, La Torre, Eugelmann, Nijhoff, Heinricius, Steyn Parvé, Treub, and De Rein.

We hope to publish abstracts of the most important papers above enumerated.

INTERNATIONAL OPHTHALMOLOGICAL CONGRESS.

[FROM OUR OWN CORRESPONDENT.]

UTRECHT, August 14th-18th, 1899.

THE Ninth International Ophthalmological Congress held its meeting last week at Utrecht under the presidency of Prof. Snellen. There were members from different parts of Europe and a strong American contingent, numbering in all upwards of 200. On Monday evening there was a public reception in the Town Hall by the municipality, followed by a concert and fireworks at the Tivoli Gardens. On Tuesday morning Dr. Argyll Robertson, who presided at the last congress held in Edinburgh in 1894, welcomed the members in a graceful address, paying tribute to the memory of Donders, who was one of the founders of the International Ophthalmological Congress, and who raised this branch of science to its high position, and complimented also his successor, Prof. Snellen, whose reputation extends to all countries. It was a happy thought of Prof. Snellen to divide the work of the Session into three sections, viz.: (a) Anatomy Section; (b), Biology and Optics; (c) Clinics and Therapeutics. Such an arrangement has become necessary to meet the demand of the ever-increasing numbers of members who offer to read papers, and to take part in the discussions. As an instance of the important papers may be mentioned Prof. Sattler (Leipzig) on Non Cataract; Professor Landolt's (Paris), Demonstration of a new Stereoscope to Exercise the Eyes for the Re-establishing of Binocular Vision; Mr. Treacher Collins (London), Demonstration of the Anatomy and Congenital Defects of the Ligamentum Pectinatum, with lantern slides. Professor Dor (Lyon), On the Treatment of Detachment of the Retina, followed by a very interesting discussion. Dr. Guttman, Berlin, cured some cases of detached retina by posterior sclerotomy; and Dr. Scheffels, Krefeld, had also two successful cases by the same operation, and maintained that now we cannot consider detachment of the retina as an incurable affection. Dr. Wolfe, Melbourne, late of Glasgow, was pleased to hear that his operation of posterior sclerotomy, which is well known in the ophthalmological literature, is gaining acceptance in the profession, and mentioned a case in which the successful result has now lasted upwards of two-and-a-half years.

The papers and the discussions were in the French, English, and German languages.

On Tuesday morning the members were photographed and a banquet given in the Tivoli gardens followed by a concert by the municipal orchestra.

On Wednesday Dr. McKenzie Davidson (London), who has done such excellent skiagraphic work, and Dr. Grassman (Liverpool) gave demonstrations of localising foreign bodies in the eyes by the X-rays. Other lectures were given by Mr. Priestley Smith (Birmingham) on Strabismus; Professor Lebert (Halle) on the Nutrition of the Eye; Dr. Panas (Paris) on Paralysis of Different Ocular Muscles, caused by injury.

Dr. Knapp (New York) on Rare Tumours of the Orbit; Mr. Anderson Critchett (London) and Dr. Berry (Edinburgh) on the Treatment of Conical Cornea; Prof. McHardie (London), on the Designs of Hospitals.

A very important paper was read by Professor von Hippel (Halle) on the Lasting Effects of the Operations for High Degrees of Myopia.

Prof. von Hippel has operated upon a large number of cases by extraction of the transparent lens, during the last six years. Of these he has kept notes, and making the patients return to his clinique for examination. He finds the results satisfactory, one of the objections against the operation being that it is

followed by detachment of the retina, he maintains that comparing the number of myopes who have been operated on, with those not operated on, they prove pretty equal. Prof. Sattler (Leipzig), spoke in favour of the operation to which he resorts in suitable cases. He finds great advantage in making the section with Weber's hollow lance. Prof. Silix (Berlin), thought the operation required great caution as it is sure to do a deal of mischief. He, Prof. Silix, observed during a period of nine months in Berlin, twenty-three cases of detached retina after extracting the transparent lens, whilst during the same period there were only three detached retinæ in non-operated cases.

Dr. Wolfe (Melbourne), late of Glasgow, said that he operated in one case in which the lens had commenced to be opaque although vision was not affected, and in another case where the cataract had considerably advanced with satisfactory result. But he could recommend it only in exceptionally rare cases. Though he admitted that the operation is almost safe in the hands of Prof. V. Hippel and Prof. Sattler, operators of great experience with a precise and splendid operative technique, and with an immense material to select their cases from, yet when reading the reports of some members of the speciality, of limited experience and less material at command, that they have extracted so-and-so many transparent lenses for myopia, he feels an oppression of the heart when he thinks that so many human eyes have been put upon the hazard, several of which must have exchanged their spectacles for total blindness. He had tried Weber's lance upon rabbits, and does not find it advantageous.

Excursions were given to members to Amsterdam, Baarn-Soetdijk, &c., and a pleasant time was spent, the weather being splendid.

Next meeting of the Congress in 1904 will be at Lausanne, Switzerland.

The Operating Theatres.

CHILDREN'S HOSPITAL, PADDINGTON GREEN.

CONGENITAL DISLOCATION OF THE HIP TREATED BY LORENZI BLOODLESS METHOD.—Mr. BURGHARD operated on a girl, æt. 3 years, who was the subject of congenital dislocation of the right hip. The affection had not been noticed until the child learnt to walk, when she was seen to waddle in the characteristic ungainly fashion. She was then brought up to the hospital. On examination there was a little over three-quarters of an inch shortening of the right lower extremity, the trochanter being that distance above Nélaton's line; there was free mobility in the vertical direction on pushing the limb up and down. While making forcible extension, the head of the bone could be felt to hitch against the acetabulum. Lordosis was well marked on standing, whilst the gait on walking was characteristic of congenital dislocation. A radiogram showed the acetabulum to be imperfectly developed, and the head of the femur out of place. The child was otherwise healthy and well developed. She was fully anaesthetised, and powerful extension was applied in order to bring the head of the bone well down opposite the rudimentary acetabulum. For this purpose a rolled up jack towel was passed round the perineum by means of which an assistant made counter extension, whilst the limb was grasped with both hands above the knee by the surgeon, who then exerted very powerful extension, and after a few minutes was easily able to bring the top of the trochanter just below Nélaton's line. Forcible traction was also made in other directions, so as to stretch the adductors and flexors of the thigh, the limb

being abducted and somewhat over-extended with this object, and the muscles thus put on the stretch being forcibly kneaded to aid their relaxation. After the muscles had thus been stretched and the head of the bone brought sufficiently down, the latter was got into position against the acetabulum by fully flexing the thigh on the abdomen and rotating the limb somewhat outwards. This procedure was accompanied by the characteristic click as the head of the bone went into position. In order to prevent a recurrence of the dislocation (which took place immediately the pressure was relaxed), the head of the bone, after being got into position, was kept firmly pressed against the rudimentary acetabulum by forcibly abducting the limb (which was still kept rotated outwards) to its utmost limit. This latter procedure occupied several minutes, as it was necessary to perform it very gradually and to knead and stretch the adductor muscles in order to obviate any risk of fracture. Finally, the limb in its position of full abduction and outward rotation was brought from a condition of flexion to that of slight hyper-extension, and held there whilst a firm plaster of Paris spica was applied, extending from below the knee (which was kept flexed) to above the iliac crests. As soon as the plaster had set, the patient was allowed to come to. Mr. Burghard said that he employed this method in preference to the open operation, because, on the whole, the results were preferable in children of the age of the patient in question. Provided that the child were quite young, but still was old enough to have learnt to walk, the prospect of the formation of a stable joint by the pressure of the head of the bone against the imperfect acetabulum was very good by this manipulative method, while at the same time the child run no risk from the shock and loss of blood entailed by the open operation, which, after all, only aimed at bringing about the same condition of affairs as that produced by the operation just performed. The objects of Lorenzi's manipulative or bloodless method were three in number. In the first place, the structures, chiefly the adductors, the hamstrings, and short flexors of the thigh, were stretched sufficiently to allow the head of the bone to be brought accurately into the cleft representing the acetabulum; secondly, the limb was immobilised for a considerable time in such a position that while the head of the bone was kept accurately *in situ*, the lax structures constituting the hip joint were allowed time to contract, at the same time the abductors became shortened to such an extent that any attempt to bring the affected limb parallel to its fellow resulted in exerting still further pressure of the head of the bone against the acetabulum. The third and most important object was, by allowing the child to walk after a lapse of a certain time to bring about a gradual deepening of the acetabulum by the constant pressure and friction exerted by the head of the femur against it in walking, and thus to establish a perfect joint. He pointed out that the operation just completed only fulfilled the first two of these objects. It would be his intention to leave the plaster casing untouched for about three months; the position in which the limb was placed, although irksome to the patient and causing some pain for a day or two owing to the stretching and tearing the muscles had undergone, would soon be tolerated. After three months the plaster of

Paris would have to be removed and a second one applied for a similar period; in all probability it would be possible when applying the second casing to diminish the abduction very considerably without any danger of the head of the bone slipping out of place, as it would then be held firmly in place against the acetabulum by the pressure of the contracted structures on the outer side of the thigh, and the knee would also be straightened so that it would be possible for the child to put the foot to the ground, although, owing to the abduction of the limb, the pelvis would necessarily be tilted; with the limb in that position the patient would be allowed to walk. In order to maintain the abducted position, a patten about an inch in height would be put on the boot of the sound side. In all likelihood, at first, the child would require crutches, but would probably soon be able to walk without their aid. After removal of the second plaster casing, which would be at the end of six months from the commencement of treatment, the patient would be allowed to walk without any splint, merely retaining the patten on the sound foot for a month or two. During all the time the child was walking, the third object of Lorenzi method (namely—formation of a stable joint by pressure and friction) would be proceeding. Of course, Mr. Burghard said the main essential in carrying out this treatment was that the head of the bone should be put accurately in place at the first sitting; should there be any doubt about this a radiogram should be taken, this can often be done through the plaster casing, but should the latter be too thick the patient should be put under an anæsthetic about a fortnight after the first operation, when the damage to the soft parts has subsided, the casing removed and a radiogram taken, and if necessary any faulty position corrected and the plaster re-applied.

Mr. Burghard afterwards showed a case which he had treated by the same method more than nine months previously with perfect success. The child walked with an absolutely normal gait, and could run about and play like other children; the hip-joint on the affected side was stable, and movement was perfect in all directions; the limbs were of equal length, and a radiogram showed the heads of the bones on the two sides to be in accurate position. This child, when operated on, was about the same age as the other. Mr. Burghard pointed out that the chances of success decreased after about the age of four, and in children of seven years and upwards his experience was that the alterations in the parts were so extreme that the operation was almost certain to fail, and it was better to have recourse immediately to the open operation. Even that, however, was not likely to be completely successful unless it were done before the child was nine or ten years of age.

The Mortality of Foreign Cities.

THE following are the latest official returns, and represent the last weekly death-rate per 1,000 of the several populations:—Calcutta 21, Bombay 30, Paris 23, Brussels 15, Amsterdam 15, Rotterdam 18, the Hague 18, Copenhagen 17, Stockholm 20, Christiania 21, St. Petersburg 29, Moscow 41, Berlin 19, Hamburg 21, Dresden 19, Breslau 31, Munich 23, Vienna 19, Prague 24, Budapest 23, Trieste 23, Rome 16, Turin (ten days) 16, Venice 23, New York (including Brooklyn) —, Philadelphia 21.

REGISTERED FOR TRANSMISSION ABROAD.

The Medical Press and Circular.

Published every Wednesday morning, Price 5d. Post free, 5½d.

ADVERTISEMENTS.

FOR A SERIES OF INSERTIONS:—Whole Page, thirteen insertions (weekly, fortnightly, or monthly), at £3 10s. 6d.; twenty-six insertions (weekly or fortnightly) at £3 3s. 0d.; fifty-two insertions (weekly) at £3 each. Half Page, thirteen insertions at 35s.; twenty-six at 32s.; fifty-two insertions at 30s. each: Quarter-page, thirteen insertions at 18s.; twenty-six insertions at 16s.; fifty-two insertions at 15s. each. One-eighth page thirteen insertions at 9s.; twenty-six insertions at 8s.; fifty-two insertions at 7s. 6d.

FOR ONE INSERTION:—Whole Page, £5 0s. 0d.; Half Page, £3 10s. 0d.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

Small announcements of Practices, Assistances, Vacancies, Books &c.—Seven lines or under, 4s. per insertion; 6d. per line beyond.

Letters in this Department should be addressed to the Publishers.

“SALUS POPULI SUPREMA LEX.”

WEDNESDAY, AUGUST 23, 1899.

NUISANCES AND SANITARY DANGERS.

A RECENT case in a London police court has emphasised the distinction between a “nuisance” and a danger to health in a somewhat instructive manner. In the mind of the multitude the two conditions mentioned constitute one and the same thing—that which is offensive to the senses must be insanitary and injurious. To take a concrete instance, the ordinary wood paving of the streets becomes in hot weather a most noisome factor of town life, and the average citizen does not hesitate to attribute to that source a long list of more or less formidable diseases, ranging from a mild ophthalmia up to a sthenic pneumonia or enteric fever. For all that, it may be questioned whether wood paving produces any more ill-effects than those that might with an equal amount of reason be attributed to the stone roadways introduced by Macadam. To put the matter in another way, bad smells do not necessarily imply a danger to health. Indeed, it may be said that in some instances an evil odour points to some degree of safety, inasmuch as it shows that the aromatic origin is open to the changes whereby nature destroys waste and dead organic matter. Many sanitarians are inclined to agree with Dr. Vivian Poore's proposition that all sewage matter should be returned to the soil, there to undergo the natural process of “humification” and fertilise the face of the earth. From that point of view the modern system of removal of sewage by water carriage is founded on a false principle, whereby the æsthetic sense of the community is saved from shock, but at the expense of the national wealth and the risk of the dangers associated with drains and sewers. The truth of the matter appears to be some-

where between the two extremes. Bad smells about a collection of houses, if they proceed from excrementitious material, are offensive and a nuisance, but are not necessarily a danger to health. If the decomposing stuff be lying about on the ground there must obviously be a risk of poisoning water and other essentials of environment. If, on the other hand, the offensive material be carried away, say in an open conduit, then the inhabitants will be safe from infection from that species of sewage disposal, however greatly it may stink in their nostrils. From the point of view herein indicated we heartily agree with Dr. Poore, and should hesitate to introduce any but open methods of sewage disposal into rural districts. From sewage to fried fish may seem a far cry, but the same principle of nuisance as apart from danger to health applies to each set of circumstances. In the case referred to at the outset of this article, the proprietor of what is often described by the newspaper reporters as a "fried fish emporium" was prosecuted for carrying on a business which was a nuisance and dangerous or injurious to health. An attempt was made to prove both general and specific injury to health, but apparently without any great measure of success. In a case of this kind it would be safer to trust to evidence, which need not be medical, as to the existence of mere nuisance. The æsthetic horror of a fried-fish shop would be testified by thousands, but, no doubt, quite as many worthy citizens would testify as to the solid comfort to be derived from that unsavoury quarter.

THE ALLEGED INCREASE OF LUNACY. IRELAND.—II.

IN our issue of last week we skirmished in a tentative fashion about the battle-ground of insanity, and would now desire to come to a little closer quarters. We are driven irresistibly to believe that sooner or later the conclusion which will infallibly impress itself upon the public is, that insanity is not increasing. The increase being apparent, and not real, is due principally to the facility of registration, the comforts, not to say luxuries, by which of late years the insane have been surrounded, thus leading to the accumulation and prolonged living which congests our asylums—the reduction which has taken place in the unregistered by becoming registered, and thus members of the happy family of the in-door. As to the expenses they are truly formidable—£350,000 for 1897—of which £68,000 was for salaries alone, and nearly £10,000 for superannuation under the ludicrously liberal administration of an Act, of which everyone who can has hitherto taken advantage—no difficult matter—as would be rendered speedily evident were we favoured, in official shape, with the full facts and details of all pensioned off since it came into operation. This appears all the more unaccountable, seeing that the grant of the Treasury towards the total expenditure is nearly £140,000, approaching the half of the expenditure (£183,000), the remainder

being levied off counties, &c., in the respective districts. It is true that somewhere about £7,000 is received from the friends of a comparatively few of the patients, which lightens somewhat the burthen, five or six thousand from the farms and gardens representing the much-vaunted utilisation of the patients, and about £2,000 from "other sources" of revenue; but, then, on the other hand, what, for example, is the outlay on the farm and gardens? nearly £11,000—repairs and alterations require £17,000—and it should be well borne in mind that this latter item is perfectly distinct from the expenditure on new structures—it is merely for patching up and repairing the old—a regular annual grant as a matter of course. The cost of such buildings as the new wings and new asylums now in progress in connection with nearly all the 22 district asylums (not including two brand new asylums in the north, and the tremendous effort of modern architectural genius at Portrane, near Dublin, intended in addition to the Grangegorman Prison to relieve the overcrowding of the Richmond Asylum, and so divert the influx of the patients thereto, as shall not only make it the standard asylum as regards its erections, patients, and staff, but bury the ghost of beri-beri which has troubled it so long), is defrayed out of funds procured by loan through the Board of Works, repayable by the respective districts in half-yearly instalments extending over 50 years, with interest at 3½ per cent. per annum. We are speaking, of course, of the immediate past, in regard to these distinct headings of expenditure, and only in a cursory manner, not thinking it necessary to give all the items—only the principal aggregates—thus the annual cost for the simple maintenance of the equipped asylums now reaches somewhat about £400,000, made up of a free Treasury grant, and levies off the districts—the estimates for which are prepared at the Castle. On the other hand, the entirely distinct and additional expenditure under the headings of buildings, land, and equipments has been always decided by the Board of Works and the Inspectors of Lunatics in the shape of the curious and little understood amalgam known popularly (or unpopularly?) as the "Board of Control"—now defunct—the District Committees being charged with the responsibility for the future, and we do not know at present time of writing of *exactly* how much of the remaining fiscal and financial arrangements, as differentiated, remains for the Castle department, which, as always an inspecting one on the best terms, should be now so, pre-eminently, if anything. To give *some* idea of the magnitude of the operations of the deceased Board of Control, we would refer those interested to a succinct statement appearing at page 32 in the 46th Lunacy Blue-Book, showing that during the decade ending in 1896 the cost of providing the already provided twenty-two elderly District Asylums with increased accommodation *still* in progress was nearly half a million, including purchase of land. There is also supplemented a return showing

the increase in accommodation provided in those asylums which have been built since 1895, and *still* in progress (five new institutions including Portrane) on an estimate of £631,600, that for Portrane alone appearing to absorb £248,600, £10,000 having been paid for the Portrane demesne. The expenditure is given to January 1st, 1897 (nearly 100,000 on the five works) and we believe the operations are still "progressing"—and as regards Portrane, we believe not yet finished—like a ball of snow gaining bulk, perhaps with the progress. We hope the committee, whose predecessors created such a storm, will finish it! Now all this (the purpose of the present article), as bearing on the increase of insanity—a very elastic subject obviously—and equally obviously its *numerical* condition may be compressed or expanded, just as you think proper to deal with it. Mr. Corbet is going on the broad ground of a crusade in the cause of humanity. We recognise it simply as a question of expenditure and common-sense. Are we in Ireland rich enough for all this expenditure? The figures given above were given, we suppose, not so much—or not at all to show the cost—but to show the "improvements" under the new *regime*. Here we leave the question for this week.

HOSPITALS AND OUT-PATIENTS.

THE dead season for the newspapers having come with the prorogation of Parliament, various discussions are being started by the editors in order to fill the columns of their journals, and the *Times* has led the way by giving prominence to a question, the debate upon which will not fail to be profitable in many ways. We allude to the correspondence which is now taking place upon "Hospitals and Out-Patients." It was commenced by a correspondent drawing attention, in terms of high praise, to the system of visiting hospitals and reporting upon them adopted by the Prince of Wales's Hospital Fund. This correspondent asserts in proof of his statements that the hospital with which he is connected was visited by three representatives of the Fund, who were distinguished for philanthropy, medical eminence and finance respectively. Of the letter itself nothing need be said, save that it must have excited a good deal of envy among the hospital authorities, whose experience of the "inspection" accorded to their institutions had not been that of the writer's. We fear, moreover, that the tendency of the letter was to lead the public to assume that all the "inspections" carried out under the authority of the Fund were of the type to which the correspondent referred. As a matter of fact, however, we know of one important general hospital at which the inspection was of a most perfunctory character. At this "inspection" we believe the medical representative failed to put in an appearance at all. While of the two others, one was a stockbroker who could be scarcely expected to know much about hospitals, and the other was the chair-

man of a similar institution who could be scarcely expected to approach his task of inquiry with an unbiased mind. Nevertheless, we merely mention these facts for the purpose of expressing our entire agreement with the correspondent in question as to the value of the method of inspection adopted by the Prince of Wales Fund if it be properly carried out. Undeniably hospitals whose managers do their utmost for the institutions have everything to gain by court- ing the fullest inquiry into their concerns. Again, it would be the worst policy imaginable upon the part of the managers to resent such inspections. But on the other hand they have the right to claim when their Institutions are visited, with a view to being reported upon, that the inspectors shall discharge their duty thoroughly and not in a perfunctory manner. Obviously, unless this be the case throughout, some institutions must suffer at the expense of others. Presumably the object of the inspection is not merely to draw attention to instances of mal-administration, and to expose faults, but also to give credit for matters worthy of favourable notice, and to commend where commendation is due. Unless, therefore, the inspectors do their duty in all instances, it is clear that well-deserving institutions might be unfairly reported upon. This point is one which we deem to be of great importance, and we trust that it will not be lost sight of by those responsible for the management of the Fund. In this connection it may be safely assumed that the more thorough and painstaking the work of the inspectors is, the greater value and respect will be attributed to their reports by hospital managers. Furthermore, there is no doubt that as soon as the public begin to understand that the Prince of Wales's Hospital Fund has by this means gained the confidence of the hospitals—a matter, be it said, of no little importance—the prosperity of the Fund in the future is certain to be assured. All, therefore, depends upon the manner with which the officers of the Fund discharge their duties; clearly their aim should be to honestly and without favour establish a *regime* for the benefit of hospitals which both the managers of the latter and the public can equally commend and endorse. There is only one other point to which allusion need be made, and that is with reference to the use made of the Inspectors' reports. Assuming that much time and thought is expended upon their production, we think that the documents should, after having been accepted by the authorities of the Fund, be handed to the various institutions to which they refer. Such documents would then be available for publication in the annual reports of the hospitals concerned, and could otherwise be made use of, under favourable circumstances, to bring the needs of the institutions under the notice of the public. By this means, no doubt, both the Fund and the various charities would eventually profit. At all events, this suggestion is one which might well be considered by the Fund. We shall refer to other matters in the *Times* correspondence in our next issue.

Notes on Current Topics.

The Plague in Oporto.

THE exclusive information we were able to publish in our issue of August 2nd, as to the probable presence of the plague at Oporto, has been unhappily borne out only too fully by the result. Within the last few days many cases of this terrible malady have been reported, and the local civic authorities have failed in their attempts to hush up the matter by suppressing telegrams and by keeping up a cordon of special secrecy. Our paragraph of August 2nd was founded on first-hand information from a high official quarter, and referred to cases of fatal sickness that had occurred at least a fortnight previous to that date. It is, therefore, somewhat interesting to note that the *Daily Mail* on the 16th August announces, with much pomp and circumstance, the fact of the plague having reached Oporto. The *Globe* rediscovered this important item of news on the 11th, and thus anticipated the *Daily Mail* by five days. For our own part both journals are heartily welcome to the use of any news that may appear in the columns of the *MEDICAL PRESS AND CIRCULAR*, although, under similar circumstances, it is our own rule to acknowledge the source of the information. As to the gravity of the general position there can be no doubt. Oporto is a place where the most elementary canons of sanitation are set at defiance. The invasion of so highly infectious a disease as plague, therefore, cannot fail to be the forerunner of a disastrous epidemic. In our own country, happily, there is little need of alarm, because we have so set our sanitary house in order that there is no prospect of filth diseases like cholera and plague gaining any real footing upon our shores. It is far otherwise, however, with the hundreds of insanitary ports scattered along the seaboard of Turkey, Italy, France, Spain, Portugal, and Belgium. We fear that the outbreak at Oporto is simply ringing up the curtain for a greater tragedy.

Tuberculosis and Syphilis.

It is generally admitted, on clinical grounds, that syphilitic infection in an individual already suffering from tuberculosis tends to aggravate the prognosis, but this is not invariably or necessarily the case. In a recent number the *Gazz. degli Ospedal*, Dr. Monteverdi relates the case of a young man who presented well marked physical and bacteriological evidence of pulmonary tuberculosis. The patient subsequently developed a syphilitic rash, and the interesting feature of the case is that as the syphilis followed its evolution, the pulmonary symptoms subsided and ultimately disappeared. Six years have now elapsed, and no return of the lung trouble has taken place. As this is not the only case of the kind which has come under the author's observation, he urges that the generally received view, even if in the main correct, must not be accepted as absolute. Observations of this kind present a special interest, because it is quite possible that the human organism may prove the battle-field of antagonistic microbes, one of which is destined to oust the other. In this connection we

may recall the suggestion, several times put forward, that an intercurrent attack of typhoid fever arrests the evolution of a previously existing attack of syphilis. We ourselves can recall one case in which this appeared to have happened, although the clinical evidence was not sufficiently conclusive to place the observation beyond the reach of criticism.

The Insanitary Pantry.

THE too frequent repetition of late of fatalities attributed to the action of alimentary toxins gives a special interest to some remarks by Dr. Stainthorpe on the subject of prevailing defects in the installation of the pantry in the modern household. The pantry is usually located in a spot where it is readily accessible to dust, and the wire gauze or perforated zinc walls which admit fresh air and exclude flies, afford no protection against its entry. In many houses any odd corner which cannot be turned to some other useful purpose is allocated to the storage of food, and the space under the stairs or some equally ill-lighted and ill-ventilated place is thought good enough for the purpose. It is often damp, and has a characteristically mouldy odour. Frequently the closet, the dust-bin, and the coal cellar are close at hand, and every facility is thus offered for the prompt action of the agents of decomposition. This is a point which curiously enough does not appear to have received anything like adequate attention by sanitarians, but as recent events have given unenviable prominence to the question of food decomposition, architects may perhaps be induced to devote a little more attention to a not unimportant detail of house construction.

Hospitals as Matrimonial Bureaux.

A DISCUSSION which ought by rights to have been relegated to the silly season, has been carried on in one or more of the New York newspapers concerning the matrimonial propensities of the nurses employed in the large general hospitals of the metropolis, though it is not pretended that the practices complained of are by any means limited to this *milieu*. The allegations in the main do not impugn the morality of the nursing fraternity, or shall we say sisterhood, but it is asserted that nurses and doctors "flirt and carry on," and that many nurses regard the hospital as a field for the matrimonial campaign. There is doubtless a certain amount of truth in this, for most of us can call to mind numerous instances of marriage between medical residents and nurses and even between nurses and their patients. Whenever a young man of prepossessing appearance is brought into daily and even hourly contact with a comely young woman, shown to advantage in a neat attire, who is not on principle averse from matrimony, there is always the possibility, *Dieu merci*, of a matrimonial sequel, and although a hospital ward is not an ideal *milieu* for Cupid's ravages, the very community of purpose and emotions paves the way to tenderer feelings. The rules at most institutions err, if anything, on the side of severity in the direction of repressing and reproving

any intimacy between medical officer and nurse, but though they may hinder flirting pure and simple, neither they nor any rules that female ingenuity, as represented by the matron, may devise, can be relied upon to stamp out this very human instinct—nor should we approve them if they did.

"In Charge of Women Lunatics."

SUCH is the title of an article in *Cassell's Saturday Journal* which is evidently meant as one of a series of educative articles on asylum management, and the life that is lead therein by nurses. We are not prepared to say that the articles are at all trustworthy, indeed, there is a tone of exaggeration in the one referred to which gives a very wrong conception of the real life that is lead in asylums by nurses. What is stated here may be perfectly true of one asylum in particular, but the manner in which the information has been obtained, expressively described by the writer, as the "back stairs" approach, is not, perhaps, the most trustworthy for information, and this may explain why a request for particulars has been refused by some well-known asylum. We cannot quite understand this, however, for nothing is more desirable perhaps in connection with asylum management than that the public should be fully informed as to the nature of asylum nursing, its advantages, and disadvantages. It would be well if the public could be brought to take a sympathetic interest in this work, and by judicious descriptions of asylum life, without any exaggeration or extenuation, something might be done to make the service more popular. In the article referred to in *Cassell's Saturday Journal*, we are told that the young woman interviewed remarked, "They call us nurses, but in many instances our position is more that of a wardress." (Perhaps she is in one of the old-fashioned asylums.) She observed also, "Many times have patients threatened to kill me. Said 'one big, raw-boned woman the other day, 'I'm only waiting; I shall be the death of you yet. I'm going to strangle you when the opportunity offers—but very, very slowly.' Have I ever been assaulted? Oh, some dozen times. Besides that, some lunatics take a fiendish delight in administering most cruel pinches whenever they get the chance. Of course, we all carry whistles to summon assistance in case of need. Sometimes a spirit of rebellion seems to break out all over the house, and you will hear the whistles going day and night." We think all this is exaggeration. We can scarcely conceive of such an asylum. It would be a perfect pandemonium from end to end. While there are some statements in the article, especially regarding strength of nerve and temperance required in nurses of the insane, which are perfectly correct, it is well to point out that hospital nursing is harder and a more severe strain on the nervous system than asylum nursing. In asylum nursing there is so much of the time in the wards fairly quiet and bearable, and there is not always the same severe tax of attention, observation, and intelligence as there is on the part of hospital

nursing. The hours are certainly not any longer, and the relaxations and the leaves of absence are more frequent and appreciable than in hospitals. On the whole, therefore, we do not think this article is quite up to the standard that such an article should attain but it certainly will not be likely to do much harm though it will not do much good.

A Police Magistrate on Sanitation.

POLICE magistrates have upon many occasions made use of their official positions to give sound instructive advice to the persons attending their courts, and we think that the opportunity in this regard which Mr. Cluer had the other day of showing the necessity of sanitation might have been taken. But we regret to have to note that he not only failed to rise to the occasion, but he has also made it perfectly plain that upon this question he is himself sadly lacking in information. A house-owner was summoned by the local vestry for failing to provide a ventilating shaft to a soil pipe, and in the course of the case Mr. Cluer said that he understood that this arrangement was one of the prime requirements of modern sanitation, "but there," he added, "no one knows where we are in this so-called sanitary science." Again, after the sanitary inspector had pointed out that in consequence of the soil pipe not being ventilated sewer gas escaped into the house the magistrate remarked, "But you have to show me that the gas is dangerous to health. In twenty years time we may have the 'sewer cure'! In the district in which I live they ventilate sewers with gratings in the roadway, so that the gas blows into our windows and doors, and yet the district is considered healthy." It is really remarkable that anyone occupying the position of a police magistrate should inquire "Is sewer gas dangerous to health?" How can the lower classes, for whom abundant excuses can be admitted, be expected to pay regard to the ordinary rules of health, when a magistrate to whom, no doubt, they naturally look for instruction, expresses himself as Mr. Cluer did the other day upon the question of sanitation. Surely, Mr. Cluer cannot believe that sewer gas is harmless to life. But if he does think so we fear that some day he may find himself sadly mistaken.

The Nuisance of Dust Carts.

THE present antiquated dust cart used by contractors in London is a fertile nuisance for two reasons, in the first place should there be any wind much of its contents are apt to be blown into the thoroughfares into the faces and down the throats of the passers-by, and secondly, at this time of the year especially, the loathsome odours which generally emanate from it are beyond description. Only quite recently the stench emitted by a dust cart was such as to render a fashionable street in the West End almost impassable. In view, then, of these facts, we are glad to see that the London County Council have taken some action in the endeavour to remedy the nuisance. A short time ago they offered

a premium of £25 for the best design for a covered dust cart. We understand that the competitors for the prize numbered no fewer than 325. In the end the design approved of was one in which the vehicle had four sliding covers with longitudinal and transverse wind guards raised about eight inches above the covers, with screw tipping gear. A box seat is also provided for the driver, which is regarded as a great improvement. We trust that the County Council will lose no time in seeing that this improved dust cart comes into practical use all over the metropolis. The wonder is that the old dust cart, with all its abominations, has been tolerated for so long.

Professional Etiquette in France.

A COUNTERPART to the remarkable subversion of ordinary, social, and judicial amenities which has of late disturbed public and private life in that country is to be found in what is now known as the Rennes-Doyen incident. On the occasion of the cowardly assault on Maitre Labori, at Rennes, M. Reclus, who is a distinguished surgeon and a member of the Academy of Medicine, was called in by the family and took charge of the case. Among those who shared in the excitement on the news of the attempted assassination reaching Paris was M. Doyen, a surgeon who, if not exactly famous, is certainly well known thanks to his ubiquitous and assertive personality. On the strength of a chance acquaintanceship with the victim M. Doyen seized his case of instruments and took the next train to Rennes, where he arrived at 4 a.m. Later on he managed to obtain access to the patient, but the brief interview was not allowed to take a professional turn, though, in taking leave, "he placed himself at the patient's disposal." As may be imagined under the circumstances, M. Reclus availed himself of the earliest opportunity to express his forcible opinion of M. Doyen's curious conduct, in fact, he absolutely refused to recognise him or to allow him to examine the patient, either alone or in consultation. In fact, he administered a well merited snub to the too enterprising Parisian surgeon. If we allude to this matter at some length it is because M. Doyen is a not infrequent visitor to our shores, where he has hitherto been received with unflinching courtesy in English medical circles. After such a flagrant breach of professional usages however, it behoves us to consider whether, in justice, this gentleman should not be received with diffidence. Certainly an English surgeon who owned to such conduct in a case of peculiar difficulty and responsibility, would be ostracised by the profession, and we have no reason to condone it in a foreigner.

A HIGHLY successful Health Exhibition has been held in Lincoln, and has attracted such crowds as to be inconvenient, and sometimes, uncomfortable; 23,000 people passed the turnstile, and many hundreds were turned away.

Local Precautions against the Plague.

FROM provincial correspondents we learn that the local authorities in the seaports throughout the country are fully alive to the necessity of taking precautions against the possible inroad of plague infection. In many cases special vigilance is already being shown in the inspection of incoming vessels, and where the latter have come from plague-infected ports, a searching examination is made by the port medical officer of the crew and ships with a view to detecting any illness among the men which could be attributed to plague. Inspectors, also, of the Local Government Board have been detailed to make special inquiry into the arrangements obtaining at the various ports. It is evident, therefore, that even if a case of plague were to reach this country, everything would be in readiness to deal with it, both as regard detection and isolation. Some doubt, however, may be expressed whether the disease could, for climatological reasons, be conveyed to these shores.

"Tuberculous" v. "Tubercular."

OUR contemporary, the *Lancet*, has very usefully opened its columns to a discussion upon the differential use and significance of the terms "tuberculous" and "tubercular." Till this correspondence began we were under the impression that a general agreement had at length been arrived at to the effect that "tuberculous" was a term to be exclusively used in connection with processes caused by the tubercle bacillus, while "tubercular" was only to be applied to diseases the physical conformation of which could be otherwise described as nodular. In other words, that tuberculous meant a specific pathological condition, and tubercular a physical one. The matter having apparently been thus satisfactorily settled, it was with much surprise that we read in our contemporary that a correspondent took exception to this application of the terms in question. In his letter he contended that "tubercular" and "tuberculous" should be used synonymously, and solely as expressive of disease caused by the tubercle bacillus, basing his argument in this regard upon philological grounds. It really makes no difference what philology or philologists have to say upon the matter. A philologist is not a pathologist, and pathologists have decided that for convenience, and in order to avoid confusion the word "tuberculous" should be exclusively limited to the description of diseases whose origin is due to the tubercle bacillus. Clearly it is obvious from this that the word "tubercular" then becomes free to be applied to the description of other diseases, not dependent upon tubercle, whose physical conformation is "tubercular," or nodular. The matter of nomenclature is thus usefully simplified and, philology, notwithstanding a confusion of terms, has been pacified. We may also add that to appeal to dictionaries in such a case is futile and pedantic. It is not to be doubted that if philological purists were to expend their energies upon criticising the names of diseases, which long usage has rendered convenient, their fault-finding would possibly not be

of a limited description. But, after all, is there any reason why we should strive after philological purism in regard to medical terms? All that is really required is a nomenclature which shall be thoroughly understood by medical men, leaving, as far as possible, no grounds for confusion, and in fulfilment of this object we consider that a great advancement has recently been made in differentiating the terms "tubercular" and "tuberculous."

The Baby Incubator Again.

IN spite of repeated protests, the rearing of babies in incubators at public exhibitions is being carried on with unabated and unabashed vigour. Another warning has come to the Earl's Court authorities in the shape of an inquest upon a child, one of triplets reared at their show. The manager of the company that provided the incubator asserted that the parents were dissatisfied because no money was paid to them. The deceased infant was eleven weeks old, and had been three weeks in the incubator. Medical evidence pointed to marasmus and inflammation of the bowels as the cause of death, and in the face of that finding it would be interesting to learn what diet is used for infants in the incubator. It is to be hoped that the Earl's Court authorities will in future do away with this most objectionable feature of their entertainment. The exposure of children under such circumstances we regard as a pandering to a morbid craving for sensation on the part of the public that is indecent, indefensible, and, moreover, open to a suspicion of inhumanity.

Restraint for Lunacy.

IN an interesting inquiry held on the 10th inst. in the High Court in London, it was decided that a lady who had been confined in a private asylum at Stoke Newington was, at the same time, mad and not mad. Her hallucination took the very usual and not unreasonable form of a belief that her relatives had shut her up in order to get her property. The evidence on their behalf showed that they could not have any such motive, inasmuch as her property was insufficient to support her in the asylum, and they had to subsidise her out of their own pockets. The eventual verdict was, that while she was too mad to manage her own affairs, and should not be allowed to do so, she was not mad enough to be put under restraint, and she was accordingly discharged.

Trade Roguery in Army Drug Contracts.

IN the Government Laboratory a series of examinations of samples sent in from the Army Medical Stores throughout the kingdom, have been conducted by Dr. Thorpe. He states that many of the samples were "markedly inferior." In one case ether supplied for anæsthetic purposes turned out to be quite inefficient, and, on examination, was found to have been made from methylated spirit, though the label bore a guarantee that rectified spirit was used. If there be no satisfactory organisation for the testing of Army drugs before acceptance there can be little doubt that drug frauds are being perpetrated, and

that, when we come to war we may find the soldier in the same unhappy condition as regards medication as he was in the Crimea.

A Peril of Counter Practice.

LAST week an attempt to rob a South London open surgery was happily frustrated by the alertness of the medical man concerned. Two men were seen to peep into the surgery, and a little later one of them came in and said he had been advised by a friend to consult the doctor. He was invited into the consulting room, and the doors being open he was examined for the "severe pain" and swelling on his left side, of which he complained. At that moment the doctor heard a suspicious noise in the surgery, and looking out saw the second man in the act of rifling the till. The bogus patient prevented his medical adviser from rushing out, but he himself was promptly secured and handed over to the police, who are giving the case their careful consideration.

Alcohol in Aerated Waters.

FOR many years past it has been a notorious fact that not a few of the herb beers and kindred drinks sold as non-intoxicant, nevertheless contain a variable amount of alcohol. One of the latest forms of the fraud, for that is the practical outcome of the position, has been recently denounced by the *Medical Temperance Review*. The plan of campaign is as follows:—Each bottle of a certain extract of herbs, which is in reality a concentrated infusion of hops, is accompanied by instructions to add so much sugar, water, and yeast, and then to set the mixture aside to ferment. Clearly the result must be an alcoholic beverage, and every fair-minded man, be he temperance advocate or otherwise, will at once endorse the energetic protest entered by the editor of the journal referred to. We should be inclined to go a step further, however, and to summon the aid of the excise authorities in dealing with this palpable evasion of the law. Whatever the rights of private individuals in the matter of brewing may be in their own houses it is open to serious question whether any firm can legally act in the manner adopted by the herb-beer makers. At any rate the temperance party would do well to bring the matter to an issue by a test case. A little action of that kind would outweigh a ton of temperance theory.

Boracic Acid in Milk.

SOME time ago Dr. Alfred Hill pointed out a fact of considerable importance with regard to the use of boracic acid as a milk preservative, namely, that the drug may be added successively and independently by various persons. A case of the kind has been reported by Dr. M. K. Robinson, Medical Officer of Health of East Kent Combined Sanitary District. He was called upon to investigate a sudden epidemic which affected five out of seven inmates of a certain household. The attack was traced to a *blancmange*, and it was found that the cook had added to both morning and evening milk supply a preservative con-

taining boric acid. Furthermore, the milk delivered by the dairyman was found to be protected in a similar way. The cumulative strength of the acid was thus considerable, so much so that five out of nine fowls died when fed with a portion of the *blanc-mange*. In the face of such facts, it is difficult to avoid the conclusion that the addition of boric acid to milk constitutes a serious menace to health. It would be a valuable contribution to practical preventive science if some authority would make an exhaustive inquiry into the immediate and remote effects of boracic acid upon man.

Coming Congresses.

THE meeting of the British Association for the Advancement of Science opens early in September, at Dover, under the presidency of Sir Michael Foster. A special feature of this meeting will be an interchange of courtesies with the French Association, which meets at Boulogne at the same date. The members from France will be officially received at Dover on September 16th, and the return visit will be made by the Britishers on the following Thursday. The municipal and military authorities at Dover and the scientific institutions are united in the effort to make the meeting a success. The various sections will be represented by the British and foreign scientists most distinguished in the subject. Marconi's wireless telegraphy and the Rev. Mr. Bacon's ballooning will be special features. The Congress of the Sanitary Institute will be held in Southampton from August 29th to September 2nd, under the Presidency of Sir William Preece, K.C.B., President of the Institute of Civil Engineers, the Chairman of the Reception Committee being Mr. G. A. E. Hussey, Mayor of Southampton, and its members include the whole of the medical profession and the leaders of the other professions in the locality. The Secretary is Mr. White-Wallis, F.S.S., who may be addressed at the offices of the Institute at the Parkes Museum, London, or at the Municipal Offices, Southampton. The members attending will be received on the 29th by the Mayor, in Hartley College, and a public luncheon will follow, after which the President will deliver his address and the Health Exhibition will be opened. Wednesday, Thursday, and Friday will be devoted to the work of sections, and on the evening of Thursday, Mr. Malcolm Morris, F.R.C.S., will deliver an address on Tuberculosis, and on Friday Mr. Baillie Dick will lecture on the Glasgow Infectious Hospitals. On these days there will also be a water trip round the Isle of Wight, and an evening reception by the Mayor, and on Saturday excursions through the New Forest and other places of interest.

DR. F. O'MARA has been appointed Resident Medical Superintendent of the Ennis District Lunatic Asylum. Dr. O'Mara was for nearly seven years Assistant Medical Superintendent of the Limerick District Asylum. There were five candidates, of whom three were from England.

M. Labori's Wound.

THE fertile resources of modern surgery are nowhere more welcome to the world in general than when they are called upon to counteract the deadly work of the assassin. At the present moment the eyes of Europe are fixed upon the distinguished French lawyer, Monsieur Labori, who, last week was shot in the back by a would-be murderer. Although the revolver used in the attempt was fired at close quarters, yet happily there is little fear of serious consequences. The immediate effects of shock and hæmorrhage were soon overcome, and the bullet has since been located by the aid of the Röntgen rays. In the hands of the French surgeons there is no room for doubt as to the early extraction of the bullet and the avoidance of septic processes in the wound. Under the circumstances, one may confidently predict the speedy return of the distinguished advocate to his duties. An interesting parallel case is the shooting of the late President Garfield. After death the bullet was found lodged in his spine, and had the Röntgen ray and aseptic methods been available at the time, the United States need not have been plunged into grief at the lingering and fatal illness of their President.

Medical Men and Repayment of Income Tax.

THERE is no difficulty in medical men obtaining the repayment of income tax. All the necessary information in connection therewith will be furnished by the surveyor of taxes for the district. It is true that the matter can be placed in the hands of agents who will apply for the money direct, but the charges of the agents amount to at least twenty per cent. exclusive of postage. We know of one instance, at all events, in which a practitioner obtained a repayment of £18, but the agents deducted £3 from the sum as their commission. Medical men, therefore, would be well advised to make the claim themselves and so save cost.

The Coming of Age of the Irish Medical Schools' and Graduates' Association.

THE above flourishing Association has just attained its majority, and the Council has decided to mark the occasion by a *conversazione* at the Hotel Cecil on or about Nov. 23rd next, after the annual dinner. Judging from the great success of the previous social functions of this Association, it may be assumed that special efforts will be made by the officers thereof to add still further to their laurels by making the contemplated "coming of age" *conversazione* a record entertainment.

THE *London Gazette* announces the appointment of Fleet Surgeon Alfred Gideon Delmege, M.V.O., M.D., to be Honorary Physician to H.R.H., the Prince of Wales, *vice* Sir Alexander Armstrong, K.C.B., deceased.

ALL Egypt has been declared infected with the foot-and-mouth disease. According to the veterinary report there have been 1,827 cases since the 18th ult.

Correspondence.

We do not hold ourselves responsible for the opinions of our correspondents.

THE NORDRACH AND FALKENSTEIN TREATMENT OF TUBERCULOSIS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The leader on this subject in your issue of May 31st last might well have provoked more discussion than it has. When it is considered how important are the points raised—important not only in view of the many hundreds of persons who to-day are seeking sanatorium treatment, but also of the immediate prospect of a large crop of sanatoria in this country. For these latter it is especially urgent that some definite idea should prevail as to which school of treatment should be taken as a model.

If we analyse the comparison which your leader gives us we find there are not any differences in theory. We must however, first eliminate some errors into which the writer has fallen in describing the Nordrach system. First, the statement that windows are removed.

This Dr. Mander Smyth and Dr. Walther himself have denied.

Second. That wet clothes are allowed to dry on the body. This is only a partial truth, the fact being that Dr. Walther teaches that it is less serious for a patient to get wet than to hurry to avoid rain, and I believe I am correct in saying that he does not advocate the retention of the wet clothes, as your leader-writer would have us believe.

Third. The obligation of patients to eat what is set before them. This is true of only two meals a day on week days, and of none on Sundays, and it must be read altogether in the light of the fact that Dr. Walther judges of each case on its own merits, is at the table himself, and supplies each patient with the quantity he considers desirable. These constitute the "Spartan" character of the Nordrach treatment.

It is greatly regrettable that your leader-writer should have mentioned under the "Falkenstein" method "the graduated walking exercise, to medical order," and "absolute rest in bed when temperature is above normal," and ignored them when summing up the Nordrach treatment; because these are especially two points in which the teachers and followers of "Nordrach" are in advance of the "Falkenstein" school. Dr. Walther insists upon absolute physical and mental rest till fever has all gone, whereas the "Falkenstein" school hold that some cases do well to be up and outside, even when the temperature is still above normal. I should like to add here that the latter teaching did not hold good in my own case, nor in any other of the number I watched.

Further, it is the "Nordrach" school which lays so much stress upon graduated exercise, and gives specific directions as to distance and pace; whereas the "Falkenstein" authorities are apt to dismiss the question with "Oh! walk a quarter of an hour twice a day." So analysed it amounts to this, that both schools advocate fresh air, plenty of food, graduated exercise, and rest for fever.

Let us inquire how these are carried out in the two classes of sanatoria. *Fresh air* at the Hohenhonnef, e.g., is taken on lounges placed within four feet of one another, in Liegenhalle, which are roofed over and permanently closed in on three sides, and often more or less on the fourth. How the dining halls are closed at meal times, your leader-writer has told us correctly. I might add that I have seen all the windows closed on a warm summer's day.

Food.—Plenty of good food is, truly, placed before patients in the sanatoria of the Falkenstein class, but who sees that it is eaten? Who encourages the weak appetite, who regulates the quantity offered? Nobody, and I have often seen the trays removed with the food almost untouched.

Graduated exercise and rest for fever have already been mentioned.

The graphic description in your leader of the airiness of the "Nordrach" dining-room needs no comment. One may add that closely placed lounges in closed-in Liegenhalle are unknown, while as to the food the personal influence exercised by Dr. Walther and his school is all in favour of food being consumed, not sent away untouched.

The sneer that patients at Nordrach must if sick go outside to vomit and return to more food is hardly fair, because in the first place many patients lose their sickness with their fever, and in the second place it is true that, as Dr. Walther teaches, plenty of good nourishing food is the cure for sickness. I have proved this on my own person, and I think that great credit should be given to him for what is a distinct advance in our methods of feeding in phthisis.

If then, sir, these are the essentials which go to make up this so-called sanatorium treatment, I submit that in addition to what your leader-writer has confessed as to the failure of Falkenstein and Hohenhonnef to carry out the fresh air rule, my own observations during an experience of several months in a sanatorium of the Falkenstein class show that the other three rules are not thoroughly observed. The balance of evidence seems to show that all four points are well attended to at Nordrach, and I cannot refrain, therefore, from expressing my hope that the managers of the sanatoria now being built and designed in this country will carry out all the principles laid down at both classes of sanatoria with a thoroughness and enthusiasm imitative of Dr. Walther, and not of that policy which your leader-writer so deliciously calls the "milder régime," which might, however, equally justly be called the "go-as-you-please" or "happy-go-lucky" régime.

I enclose my card.

I am, Sir, yours truly,

ANOTHER M.D.LOND.

MODERN IMPROVEMENTS IN DIAGNOSTIC APPARATUS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—With many of the statements contained in your leader of the 16th inst. upon the above subject every open-minded practitioner will probably agree. It would be well, however, to accept with some amount of caution your emphatic assertion that "Fortunately the antipyretic wave has passed its apogee, and practitioners are beginning to employ these powerful and even dangerous drugs with caution." Passing over the editorial *lapsus calami* that leaves to the acuteness of the reader to find out by inference what drugs are meant, we may pass on to consider what was evidently the writer's intended proposition, namely, that antipyretic drugs are not only dangerous, but are actually falling into disuse.

Now, after nearly a score of years passed in the active practice of medicine, I can only say that for my own part I should feel myself deprived of a trusty weapon at the bedside if my antipyretic drugs were taken away. Everyone knows that long-continued high temperature is invariably fatal. Everyone knows, also, that quinine lowers temperature quickly and safely, and I can recall at least half a dozen severe cases of enteric fever in which recovery was to be attributed, so far as human judgment can decide, to prompt and full dosing with quinine.

At the same time I admit that of late years I have trusted far oftener to antipyretic measures, such as the bath and cold sponging.

The old system of dosing patients with narcotics I condemned from an early period of practice, as it seemed to me illogical to narcotise the nerve centres while leaving the *fons et origo mali* untouched. The use of antipyretics, however, is founded on a rational system, for it checks the ill effects of high temperature condition upon the muscular structures of the heart and other important organs.

Trusting you will pardon these few words from one who is content usually to play the part of an onlooker,

I am, Sir yours truly,

MEDICUS IGNOTUS.

Folkestone, Aug. 20th, 1899.

[We are afraid our correspondent has been inclined to devote his criticisms rather to one particular sentence than to the drift of the whole article to which he refers. In the main we have no difficulty in endorsing his views.—ED.]

Obituary.

PROFESSOR BUNSEN.

ROBERT WILLIAM BUNSEN, of Heidelberg University, passed away on the 15th inst., at the ripe old age of eighty-eight. His name and reputation are perpetuated by the universally used Bunsen burner and the electric battery which he invented, but his chief work and success were in the field of chemistry. He it was who discovered that precipitated ferric hydroxide is a certain antidote in arsenical poisoning, and his work on Cacodyl compounds of ammonia and arsenic opened up a new area for the inquirer. His great work was in spectrum analysis, which, with the aid of his colleague Kirchhoff, he brought almost to perfection. He was born at Göttingen in 1811.

Literature.

MEDICAL GYMNASTICS. (a)

THIS handbook is the second edition of a work which is already well known to those who make this subject a special study. It has been translated into several languages and has been adopted as a standard at many institutions where attention is devoted to the treatment. The author first describes the principles which underlie the various coordinated movements described in detail, and explains the simple apparatus required for them. He then proceeds to discuss the diseases and deformities in which carefully graduated gymnastic exercises have proved beneficial, and it is to this part of the work that we would especially direct the attention of our readers. It is indispensable that the medical adviser should be in a position, not only to select cases likely to be benefited thereby, but also to direct the nature and degree of the movements required in each individual case. That is especially the case outside our large towns, because in country districts skilled assistance is not usually available, and the medical man must not only advise but must himself teach the attendants to carry out his instructions. From this point of view Dr. Wide's book will be found exceedingly useful. The author points out incidentally that the benefits accruing from methodical exercise of this kind are not limited to actual disease or deformity, but may advantageously be had recourse to as a means of overcoming the tendency to plethora and obesity which characterises persons addicted to sedentary occupations, and too generous a dietary. The illustrations are numerous, and are sufficiently explanatory, though they can hardly claim to rank as works of art. The English, too, is occasionally halting and ambiguous, in fact, the "get up" of the work is not altogether on a par with the value of the work as a guide and a valuable method of natural treatment. It is published by Sampson, Low, Marston, and Co., at 10s. 6d. net.

NEW BOOKS AND NEW EDITIONS.

THE following have been received for Review since the publication of our last monthly list:—

BAILLIÈRE, TINDALL AND COX (London and Paris).

The Röntgen Rays in Medical Work. By David Walsh, M.D. Second edition. Pp. 258, with 103 illustrations. Price 10s. 6d.

(a) "Handbook of Medical Gymnastics." By Anders Wide, M.D., of Stockholm. 8vo., 381 pp. Price 10s. 6d. net. London: Sampson, Low, Marston, and Co. 1899.

Cure prompte et Radicale de la Syphilis. Par le Dr. J. F. Larrien, Laureat de la Faculté de Médecine, Paris. Pp. 134. Price 4 francs.

BALE, SONS, AND DANIELSSON, LTD. (London).

Essays and Nature Studies. By W. J. C. Miller, B.A. Lond. Edited by H. Kirke Swann. Pp. 220. Price 10s. 6d. net.

BLAKISTON, SON, AND CO. (Philadelphia).

Pulmonary Tuberculosis, its Modern Prophylaxis and Treatment. By S. A. Kropp, M.D. Pp. 342. Price 3 dols.

CASSELL AND CO., LTD. (London).

The Cerebro-Spinal Fluid; its Spontaneous Escape from the Nose. By St. Clair Thomson, M.D., M.R.C.P. Lond., F.R.C.S. Pp. 140. Price 5s.

Intestinal Obstruction, its Varieties and Treatment. By Frederick Treves, F.R.C.S. New Edition. Pp. 565. Price 21s.

HENRY J. GLAISHER (London).

Asthma: Recent Developments in its Treatment. By Ernest Kingscote, M.B., L.R.C.S., Ed. Pp. 184. Price 5s.

CHARLES GRIFFIN AND CO., LTD. (London).

Atlas of Urinary Sediments, with Special Reference to their Clinical Significance. By Dr. H. Rieder. Translated by Dr. F. C. Moore, and edited by A. S. Delepine, M.B., C.M. Ed. Price 18s.

LEWIS, H. K. (London).

Extra-Uterine Pregnancy: A Clinical and Operative Study. By John W. Taylor, F.R.C.S. Pp. 205. Price 7s. 6d.

Skiagraphic Atlas of Fractures and Dislocations. By Donald J. Mackintosh, M.B. Demy quarto, 12s. 6d. net.

Enlargement of the Prostate, its Treatment and Radical Cure. By C. Mansell Moullin, M.D. Oxon., F.R.C.S. Pp. 212.

LONGMANS, GREEN AND CO. (London and Bombay).

The Value of Electrical Treatment. By Julius Althaus, M.D., M.R.C.P. Lond. Pp. 165. Price 3s. 6d.

MACMILLAN AND CO. (London).

A System of Medicine by many Writers. Edited by Thos. Clifford Allbutt, M.D., LL.D., F.R.C.P. Lond., F.R.S. Vol. VII. Pp. 937. Price 25s. net.

KEGAN PAUL, TRENCH, TRUBNER AND CO. (London).

Evolution by Atrophy in Biology and Sociology. By Jean Demoor, Jean Massart, and Emile Vandevelde. Translated by Mrs. Chas. Mitchell. Pp. 322. Price 5s.

YOUNG J. FENTLAND, (Edinburgh and London).

The Relation of the Nervous System to Disease and Disorder in the Viscera. By Alexander Morison, M.D., F.R.C.S. Ed. M.R.C.P. Lond. Pp. 132.

RIVINGTON, MESSRS. (London).

The Essentials of School Diet. By Clement Dukes, M.B., B.S. Lond. Pp. 212. Price 6s.

SCIENTIFIC PRESS (London).

Medical Gymnastics. By Axel v. Grafstrom, M.D. Pp. 138.

Medical News.

Vital Statistics.

THE deaths registered last week in the thirty-three great towns of the United Kingdom corresponded to an annual rate of 24.3 per 1,000 of their aggregate population, which is estimated at 11,404,408 persons in the middle of this year.

Birkenhead 18, Birmingham 27, Blackburn 14, Bolton 19, Bradford 20, Brighton 23, Bristol 17, Burnley 26, Cardiff 19, Croydon 19, Derby 21, Dublin —, Edinburgh —, Glasgow —, Gateshead 21, Halifax 16, Huddersfield 13, Hull 21, Leeds 21, Leicester 20, Liverpool 33, London 23, Manchester 32, Newcastle-on-Tyne 22, Norwich 23, Nottingham 28, Oldham 21, Plymouth 36, Portsmouth 27, Preston 24, Salford 28, Sheffield 30, Sunderland 17, Swansea 17, West Ham 28, Wolverhampton 19. The highest annual death-rates per 1,000 living, as measured by last week's mortality, were:—From measles, 2.6 in Sheffield, 2.8 in Burnley; from whooping cough, 1.0 in West Ham; from fever, 1.2 in Wolverhampton; and from diarrhoea, 5.2 in Leeds, 5.3 in London and in Hull, 5.4 in Derby, 5.7 in Croydon, 5.8 in Bristol, 6.1 in Leicester, 6.4 in Norwich, 6.5 in Sheffield, 6.8 in Birmingham, 7.0 in Nottingham, 8.3 in Burnley, 8.4 in Manchester, 8.7 in Bolton, 9.3 in Liverpool, 9.8 in Plymouth, 10.4 in Portsmouth, 11.1 in West Ham, and 11.2 in Salford. In none of the large towns did the death-rate from scarlet fever reach 1.0 per 1,000. The 75 deaths from diphtheria included 26 in London, 8 in West Ham, 8 in Sheffield, 6 in Leeds, 3 in Leicester, 3 in Salford, and 3 in Blackburn. One death from small-pox was registered in Hull, but not one in any other part of the United Kingdom.

Notices to Correspondents, Short Letters, &c.

✎ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

LOCAL REPORTS AND NEWS.—Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sending them to the Editor.

READING CASES.—Cloth board cases, gilt lettered, containing twenty-six strilgs for holding the numbers of THE MEDICAL PRESS AND CIRCULAR, may now be had at either office of this journal, price 2s. 6d. These cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

REPRINTS.—Authors of papers requiring reprints in pamphlet form after they have appeared in these columns can have them, at half the usual cost, on application to the printers before the type is broken up.

ORIGINAL ARTICLES OR LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

K. K. W.—1. What is the exact nature of the malady? In a case of the kind you describe it is impossible to advise merely upon general information. 2. You had better consult a specialist. 3. We can supply you with a list of books, but you will do better to consult the Librarian at the Royal College of Surgeons when next you visit London.

DR. HARTROP.—Sea-bathing is not likely to do any harm under the circumstances you mention.

W. D. (Bacup).—We cannot give medical advice, but may say that a good plan of administering cod-liver oil is to give it in milk just before going to bed. Why not try Scott's, or some other good emulsion?

JUST TO SPITE THE DOCTORS!

CHAMPAUDET had a doctor friend who had formally forbidden him to smoke in the interest of his health. The two friends fell out, as so many others have done, over the Dreyfus business, and now whenever Champaudet meets his doctor friend he ostentatiously lights a gigantic cigar—just to spite him.

QUERENS (Folkestone).—The late Sir George Humphry reported some observations that bear on your questions. He made notes on forty-six centenarians, of whom one only consumed alcohol in large amount, whereas fifteen of them were total abstainers, and twelve of the fifteen had not taken alcohol at any period of their lives. Of the remainder, twenty-four took very little, while six were moderate drinkers. It is hardly necessary to point out that statistics of this kind want careful handling. Much injury has always been done to the cause of temperance, which is in itself most excellent, by over-statements on the part of zealous advocates. *Verbum sap.*

ALLY SLOPER IN STRANGE PASTURES.

We have not, so far, included "Ally Sloper" among our exchanges. Judge then of the editor's surprise at receiving by post, *franco*, a certificate conferring upon him 'he membership of "Sloper's Club," which, we rather, meets on the pavement in front of the office. In addition to other privileges, membership of this club confers the right to make use of the letters M.O.S.C., but we have doubts as to the admission of this "distinction" to the pages of the "Medical Directory."

LATMAN.—The preparation is a secret one, but any analytical chemist would doubtless be prepared to analyse it on payment of his fee.

THE LEICESTER GUARDIANS.

The forty-five Guardians of Leicester,
Have plainly determined to fester—
In the heat and the gaol
Of the town whence they hail,
Their conscience, 'gainst vaccine's a tester.

WESTRALIAN.—Human rumination is a well-known condition, but no constant anatomical lesion has been found to be associated with it. For the most part, it is neurotic in its origin, while heredity plays an important role in this connection. No special treatment of the disorder has proved of use, though when it depends upon indigestion lavage may be strongly recommended.

GUARDIAN (Calcutta).—Every information will be found in our forthcoming students' number, to be published on September 13th next.

HOUSE PHYSICIAN.—We shall be glad to have the notes of the case.

SURGEON.—The man might possibly be able to recover some sum as damages under the Workmen's Compensation Act.

F.R.C.S.—Our correspondent will find the information which he seeks in our editorial columns.

P-TCROLOGIST.—We are not aware that such a work has been published, but will cause inquiries to be made into the matter.

LOCUM TENENS.—Our correspondent must first be sure of his

facts; but if he has trustworthy reasons for supposing that the gentleman named is unqualified, and is yet in sole temporary charge of the practice, we think that his duty would be to report the matter. He should communicate the facts to the secretary of the Medical Defence Union.

Appointments.

BISSET, E., M.B., Ch.B., has been appointed Resident Physician to the Aberdeen Royal Infirmary.
COATES, C. J. A., L.R.C.P. Edin., L.F.P.S.G., Medical Officer for the Tenth Sanitary District of the Wycombe Union.
COTTON, WILLIAM, M.A., M.D., C.M. Edin., D.P.H. Cantab., pro tem., Honorary Medical Officer to the Royal Victoria Home, Brentry.
CLATTON, W. A., L.R.C.P., L.R.C.S., L.F.P.S. Glasg., Medical Officer for the Sharnston and Crofton Sanitary Districts of the Wakefield Union.
DODD, A. M., M.R.C.S., L.R.C.P. Lond., Assistant Surgeon to the Liverpool Dispensaries.
GORMAN, E. S., M.B., Ch. Irel., Assistant Resident Medical Officer to the Workhouse Infirmary of the Parish of Birmingham.
HODSON, T. G., M.D. Durh., L.R.C.P. Lond., M.B.C.S., Medical Officer for the Fourth Sanitary District of the South Stoneham Union.
JOYCE, Dr., Officer and Public Vaccinator for the Cymmer Sanitary District of the Pontypridd Union.
MEAKIN, ETHELDA B., M.B. Lond., Assistant Medical Officer to the Grove Hospital, Lower Tooting (Metropolitan Asylums Board).
MELDRUM, W. P., M.B., Ch.B., B.Sc. Edin., Assistant Surgeon to the Liverpool Dispensaries.
MILLARD, C. KILLICK, M.D., D.Sc. Pub. Health, Medical Officer of Health for the Borough of Burton-on-Trent.
MORETON, R., L.R.C.P. Lond., M.R.C.S., Medical Officer for Wymondham Sanitary District of the Melton Mowbray Union.
O'MARA, F., L.R.C.P., L.R.C.S. Irel., Resident Medical Superintendent for the District Lunatic Asylum, Ennis, co. Clare.
PROUDFOOT, F. G., M.B., C.M. Edin., Medical Officer for the Sanitary District of the Oxford Incorporation.
ROWLAND, F. M., M.D. Cantab., L.R.C.P. Lond., M.B.C.S., Medical Officer for the Workhouse of the Lichfield Union.
STORRS, R., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., Medical Officer for the Thorncombe Sanitary District of the Bedminster Union.
SUTHERLAND, A. W. M., M.B., Ch.B., Resident Surgeon to the Aberdeen Royal Infirmary.

Vacancies.

Belmullet Union, Knocknallower Dispensary District.—Medical Officer Salary £130 a year, with £10 a year as Medical Officer of Health, together with Vaccination and Registration Fees. (See advertisement).
Berry Wood Asylum, Northampton.—Senior Assistant Medical Officer for five years, unmarried. Salary £200, rising to £250, with board, lodging, and washing, &c.
Brighton and Hove Lying-in Institution and Hospital for Women. 76, West Street, Brighton.—House Surgeon, unmarried. Salary £80 per annum, with furnished apartments, board, gas, coals, and attendance.
Denbighshire Infirmary, Denbigh.—House Surgeon for twelve months. Salary £100 per annum, with board, residence, and washing.
Durham County Asylum, Winterton, Ferry Hill.—Assistant Medical Officer, unmarried. Salary £120, with apartments, board, and attendance.
Manchester Children's Hospital.—Junior Resident Medical Officer for six months, unmarried. Salary at the rate of £90 a year, with board and lodging. Apply to the Secretary, Dispensary, Garside Street, Manchester.
Metropolitan Asylums Board.—Assistant Medical Officers at the Fever and Small-pox Hospitals, unmarried. Salary £160 per annum for the first year, and subject to the direction of the Hospitals Committee, £180 the second year, and £200 the third and subsequent years, with board, lodging, attendance, and washing subject to statutory deductions. Applications to the Clerk to the Board, Norfolk Street, Strand. (See advertisement).
Rochdale Infirmary and Dispensary.—House Surgeon, unmarried. Salary £90 per annum, with board, residence, and laundry.
Royal Halifax Infirmary. Assistant House Surgeon, unmarried. Salary £50 per annum, with an extra allowance of £9 2s. 6d. per annum, and residence, board, and washing.
Tubercular Union.—Analyst to the Board of Guardians. Application to the Clerk of the Union. (See advertisement).
Victoria Hospital, Folkestone. House Surgeon. Salary £80 per annum, rising to £100, with board, residence, and washing.
Westminster Hospital, S.W.—Pathologist. Salary £250 per annum, and £80 per annum will be allowed for expenses, including the services of an Assistant.

Births.

TAYLOR—August 18th, at Kidlington, Oxon, the wife of Frederic H. A. Taylor, M.R.C.S., L.R.C.P. Lond., of a son.

Deaths.

HERRON.—On August 11th, at Southwark Bridge Road, Jame. Herron, M.D., Medical Officer of Health for the parishes of St. Saviour and Christ Church, Southwark, aged 42 years.
HICKS.—On August 14th, at Longmead, Buntingford, Francis Edward Hicks, F.R.C.S., in his 90th year.

THE PATHOLOGY OF RENAL GROWTHS. (a)

By T. N. KELYNACK, M.D., M.R.C.P.
(Manchester).

It was in 1883 that Mr. Paul, of Liverpool, with the co-operation of several British and American pathologists attempted to formulate a scientific classification of new growths arising in connection with the urinary system. The record of this private collective investigation acted as an immense impetus to the more thorough examination of renal growths, and it is but seemly that we should now review the results which time and numerous workers have brought us.

And yet in spite of much research we have still to deplore the meagreness and uncertainty of our conclusions. The great bulk of published cases are rendered practically useless for pathological purposes from the only too cursory and superficial nature of the examination or description of the histological characters of the growth. Clinical records are not lacking in completeness, but only too frequently they are not associated with detailed pathological descriptions. Even recent cases are in too many instances accompanied by only sparse or unreliable histological particulars, and the days of loose nomenclature are not yet passed. Only by an exhaustive investigation of every case of renal growth can sufficient material be accumulated to furnish data for formulating a trustworthy classification which shall indicate not only the genera of these growths but their respective clinical features.

CLASSIFICATION.

It is manifest, therefore, that any grouping must still be more or less tentative. A desirable division should be such that while pathologically correct it may be clinically useful. It must indicate (1) the structural characters; (2) the seat of origin; (3) the period of development; and (4) the local and general tendencies of the growth.

In attempting to arrange any convenient classification of renal growths, it is essential to recognise such long established facts as the following:—

1. A certain number are of congenital origin, while the majority manifest themselves subsequent to birth.

2. Some few are simple or benign in character, while the majority are malignant.

3. They may be solid or assume cystic forms.

4. Histologically they conform to the two great tumour groups: (a) those of connective-tissue type; and (b) those of an epithelial type; but complex forms not infrequently occur.

5. They vary considerably as regards their seat of origin.

It is, moreover, necessary in arranging any complete classification which may be satisfactory clinically to recognise the further fact that certain growths arising in connection with extra-renal

structures cannot, at least in the majority of cases, with our present knowledge, be distinguished during life from true renal growths.

For some time to come we shall probably be compelled to rely mainly on structural arrangement as a basis for systematic grouping.

The following may, I venture to think, be submitted as at least a convenient and tentative classification which shall pave the way to a more perfect grouping.

1. True renal growths.

- | | | |
|---|-------------|----------------|
| 1. Originating from inter-tubular connective tissue ... | { Benign | { Fibroma, &c. |
| | { Malignant | { Sarcoma |
| 2. Originating from renal epithelium ... | { Benign | { Adenoma |
| | { Malignant | { Carcinoma |

2. Pelvic growths, generally malignant papilloma.

3. Capsular growths, generally sarcoma.

4. Hilum growths, generally sarcoma.

5. Growths from adrenal inclusions.

- | | | |
|-------------------------|-------------|-----------|
| 6. True adrenal growths | { Benign | { Adenoma |
| | { Malignant | { Sarcoma |

- | | |
|-----------------------|----------------|
| 7. Peri-renal growths | { Fibro-lipoma |
| | { Sarcoma |

GENERAL CONSIDERATIONS.

Primary renal growths are by no means common. I find from an examination of our Manchester records that they are met with in a little less than 1 per cent. of all cases submitted to autopsy. This seems to be in accord with the experience of pathologists elsewhere. In my experience they form from 2 to 3 per cent. of all cases of primary malignant disease. Even secondary growths of the kidney are far from common. From our hospital reports I estimate that they occur in about 8 per cent. of all cases of carcinoma, and over 14 per cent. of all cases of sarcoma.

Renal sarcomata seem to be the commonest form of abdominal growth met with in children.

Comparatively little is known regarding the causation of renal growths. They are shrouded in the mystery which more or less envelopes all true tumour formations. Strong evidence, however, is forthcoming to suggest that some may be accounted for by embryonic defects such as a faulty segmentation of the pro-vertebral somites, development of heteroplastic remnants of the Wolffian bodies, or, perchance, from adrenal inclusions.

Hereditary predisposition is not a marked feature of these cases, and traumatism although claimed by some writers, is probably of little or no influence as a cause. Attempts have been made to show that there is an ætiological connection between renal calculi and growth, similar to that which undoubtedly exists between gall-stones and carcinoma of the gall-bladder, but apparently this is not the case.

Renal growths occur in all races, in both sexes, among all classes and at all ages. Several have been met with in negro children. Most authors claim that males are more frequently affected than females. From an analysis of a large number of cases I find

(a) Abstract of an Address introductory to a Discussion at the Annual Meeting of the British Medical Association, Portsmouth, August 3rd, 1899.

that there is practically no difference in the two sexes. In the growths met with in childhood girls would appear to be a little the most liable. As to the influence of sex in connection with the various forms of growth our present data are comparatively worthless.

The influence of age is very striking. From an analysis of 160 collected cases I find that 84 or over 52 per cent. were met with below 10 years of age, and of these no less than 74 were met with below 5 years. It has been conclusively shown that renal growths may arise during intra-uterine life.

From the standpoint of age renal growths may be conveniently classified into:—

1. Fœtal or congenital growths.
2. Growths in infancy and childhood.
3. Growths of active adult life.
4. Growths arising in declining life.

The pathological importance of this division will be evident later.

Little need be said here respecting the general character of renal growths. These are best referred to when the individual forms are under consideration. As regards actual size there is every variety. The sarcomata often reach immense proportions. The carcinomata are usually much smaller. The average weight of sarcomata in twenty-four whose average age was three years, was over 124 ozs.

In perhaps the majority of cases the reniform shape is retained. The variations in colour are mainly dependent on the varying vascularity of the growth or the occurrence of degenerative changes. The consistency also varies greatly, the sarcomata and malignant trabecular cystomata being usually soft and friable, while the adenomata and carcinomata are generally more or less firm and dense. There is practically no difference in the frequency with which the different kidneys are affected; in the sarcomata particularly the striated forms met with in infancy a bilateral involvement is frequent.

GROWTHS OF A CONNECTIVE TISSUE TYPE.

We may now proceed to consider the different growths which are conveniently classed as those of connective tissue type. These may be divided into—(1) the simple or so-called benign forms, and (2) the malignant forms or sarcomata.

SIMPLE OR BENIGN GROWTHS.

These are extremely rare and of little or no practical importance. They are usually of a fibro-lipomatous nature.

A *Fibroma* occurs as a firm, small rounded nodule. Some of those recorded may possibly have been adenomata. Several cases are on record where large fibro-cystic or fibro-lipomatous growths have been removed by operation. Probably some of these were really peri-renal in origin.

A true *lipoma* of the kidney is exceedingly rare. Some of the so-called lipomata have been shown to be developments of aberrant adrenal tissue. Undoubtedly some of the fatty renal growths on record have been developed from circumrenal structures.

Curious *angiomatous* growths are occasionally met with. In some instances they closely resemble in general structure the cavernous angiomata of the liver. Occasionally more complex forms are met with. Some of the trabecular cystomata may present a strikingly vascular appearance. The other forms of simple growths of the so-called connective tissue type are mere curiosities, and call for no special note.

THE RENAL SARCOMATA.

The great bulk of growths of the kidney belong to the malignant connective tissue type. These sarcomata may perhaps most conveniently be divided;

1. According to the age of the subject in which the growth develops.
2. According to the seat of origin.

3. According to the histological characters.

They vary greatly in their form and general appearance. Some are solid throughout, but others tend to a cystic formation. Usually they grow rapidly and tend quickly to destroy life.

SARCOMATA CONSIDERED WITH REGARD TO PERIOD OF LIFE.

Fœtal Sarcomata.—It is now generally recognised that renal sarcoma may originate during intra-uterine life. Probably a number of those met with early in infancy commence their development before birth. The rhabdo-myomata, as they are called, certainly often commence their growth at a very early period.

The Sarcomata of Infancy and Early Childhood.—The first five years of life are peculiarly liable to malignant disease of the kidney, and I believe the form of tumour is nearly always of a sarcomatous type. From an analysis of a large number of cases I find that over 46 per cent. of those met with in childhood occur under three years of age. My numbers also tend to show that girls are a little more liable than boys. If this proves to be the case it raises an interesting embryological point. In about half of the cases the kidneys are involved bilaterally, thus conforming to what seems to be more or less a general tendency as regards paired viscera. They grow rapidly, and often assume enormous dimensions. Usually they give rise to but little pain, and urinary symptoms are generally inconspicuous. The ureter is not often invaded, but the veins are almost always encroached upon, and secondary deposits may occur in the lungs, liver, and lumbar, mesenteric and vertebral glands.

The Sarcomata of Adult Life.—Although specially associated with the first few years of life, sarcoma may develop at any age. Strange to say it is very rare during the period of youth when general development is rapid. The years from five to thirty are peculiarly free from the tendency to malignant renal growth. From my collected cases I find adult females distinctly more liable than adult males.

SARCOMATA CONSIDERED ACCORDING TO SEAT OF ORIGIN.

This is a practical grouping, and one of much interest both to pathologist and to the surgeon.

I think we may recognise the following:—

1. Capsular and sub-capsular.
2. Intertubular.
3. Hilum.
4. Peri-renal tissue.

1. Sarcomata arise in connection with the renal capsule in much the same way as they do in connection with the capsule or periosteum of bone. Unless a renal sarcoma is met with in an early stage it may be difficult to venture an opinion as to its precise seat of origin. There are, however, several cases on record and several in our public museums which conclusively show a growth originally in the capsule, and with the kidney displaced or flattened and sometimes separated from the growth by fibrous tissue. In these cases the growth may spread beneath the capsule, encroach on the renal cortex, or perforate the capsule and envelope the kidney.

2. The intertubular sarcomata arise in the connective tissue of the cortex and medulla, or perhaps in some cases from the peri-vascular and peri-lymphatic structures.

In this form the growth infiltrates the kidney substance. The capsule in early forms can be readily seen covering the growth. Often kidney tissue can be detected surrounding or extending over the tumour.

The sarcomata met with in adults seem generally to belong to this class.

3. The growths originating in the hilum constitute a most important and interesting class. The connective tissue around the pelvis and calyces form the starting-point. A large number of the sarcomata in children develop from these elements. This class has been more particularly studied by Mr. Targett.

The growth at first lies without the renal substance, and it is only after some time that the kidney becomes encroached upon, expanded, replaced, or flattened out so as to be rendered almost unnoticeable.

4. The *peri-renal sarcomata* although strictly extra-renal, may perhaps be best briefly referred to here. Clinically they very closely resemble true renal growths. They originate in connection with the connective tissue elements of the fatty capsule of the kidney, and often consist in great part of lipomatous tissue, with variable amount of fibrous tissue, but generally presenting more or less evident sarcomatous cells. They usually develop slowly, often reaching an enormous size.

SARCOMATA CONSIDERED IN RELATION TO THEIR STRUCTURE.

This is perhaps the most interesting and instructive division, and certainly the most fascinating to the student of morbid histology. It suggests relationships and affinities, and already we can recognise clinical differences according to structural arrangement. The complicated combinations not infrequently met with still make the question one of considerable perplexity and uncertainty.

1. The majority of the sarcomata consist of *round* and *spindle* cells in varying proportion. The round seem to be the most rapidly growing and malignant in character.

2. The striated cell sarcoma often spoken of as the *rhabdo-myoma* is met with almost exclusively in the fetal forms and those arising during infancy. Indeed, this variety is by some spoken of as "congenital sarcoma." Mixed with the round cells are elongated and transversely striped cells. They are generally smaller and thinner than true muscle cells and have no sarcolemma. Much variation in size and degree of striation occurs.

It has been suggested that this peculiar form of cell arises from inclusion of muscle elements, due to faulty segmentation of the primitive muscle plates. Some believe that the striated cells are derived from the muscle tissue of the renal pelvis. Others think the fibres are not to be looked upon as muscle elements at all but merely ribbings in the surface of a tissue which is not contractile. It is suggestive to note that this type of cell is met with especially in hilum growths.

These growths as already indicated are very frequently bilateral, although one kidney may be much more involved than the other. I recently had the opportunity of carefully investigating a striking example met with in a child one year old. The right kidney formed a huge mass 9 ins. by 8½ ins., and weighed 108 ozs. The left kidney was much smaller and weighed 28 ozs.

In many of these so-called myo-sarcomata curious duct-like structures are met with. In some cases they appear like sections of tubules lined with columnar epithelium. Apparently they are derived from the renal tubules, and some observers have considered them as stranded uriniferous tubules encroached upon or surrounded by sarcomatous tissue.

3. Very vascular growths or angio-sarcomata are occasionally met with. I am inclined to believe that they arise more particularly in connection with the perivascular tissue. They sometimes seem to arise in the hilum and encroaching on the pelvis give rise to profuse hæmaturia.

4. A certain number of the sarcomata present a

distinct although variable amount of glandular like tissue mixed up with the true sarcoma cells. These *adeno-sarcomata* constitute a very definite variety. The gland-like elements usually occur as groups of tubules, lined by well defined cubical or columnar epithelium, and more or less closely resemble the tubules of a fetal kidney, but sometimes the epithelial elements have a less definite form and arrangement. They certainly occur in young subjects. Striated cells are also sometimes present.

5. *Complex forms* presenting a complicated arrangement occasionally occur.

Alveolar sarcoma has been described, and is thought to arise in connection with the endothelial lining of lymphatic or vascular channels.

Myxo-sarcoma is simply one of the ordinary forms in which myxomatous degenerative changes have occurred.

Lipo-sarcoma has been described, but I am inclined to think that most of these are really of peri-renal origin.

Melanotic sarcoma is always secondary. The kidneys are frequently involved when general dissemination takes place.

GROWTHS OF AN EPITHELIAL TYPE.

These include the adenomatous growths and true carcinomata.

The *simple adenomata* form a small and unimportant class. They may be met with as single or multiple nodules, limited in extent and usually in size. According to their structural arrangement solid or granular and cystic forms may be recognised. Some pathologists further divide them into papillary and alveolar varieties.

They occur as small nodules in the renal substance, varying in size from a pin's head to a small marble. The proportion between amount of cells and stroma is variable.

The *trabecular cystomata* are perhaps best classed in this group. Transitional forms are not infrequent. Some have thought that they have affinities to the growths of adrenal origin, but this seems doubtful. These simple forms appear as an aggregation of minute cysts. Each cyst is lined with cubical or columnar epithelial cells.

The *papilliferous cystomata* present malignant characters, and must be regarded as closely related to the true carcinomata. They show more or less extensive papillary ingrowth, each covered with a single layer of columnar or cubical epithelium. The varying complexity of the papilliferous formation depends probably upon rate of growth, and adaptation to the adjacent tissues. The vascular character is often very conspicuous. Sometimes an almost angiomatous appearance is assumed. They appear to originate in connection with the convoluted tubercles, and are liable to degenerative changes. Dissemination occurs. I recently had the opportunity of examining such a growth in a woman, æt. 33. The liver presented enormous masses of growth which closely recapitulated the structure of the growth in the kidney.

CARCINOMATA.

Until recently our nomenclature has been so indefinite that it is exceedingly difficult to make any use whatever of the old records respecting "cancer" of the kidney. Undoubtedly many of these were really sarcomatous. Of recent years the sarcomata have almost monopolised the attention of pathologists. The study of the carcinomata has been greatly neglected. We are thus left with inadequate material for satisfactorily classifying the varieties or forming anything like a complete description of this class of renal growth.

Indeed, at the present time, it is almost hopeless to

attempt to do more than indicate approximately the general characters of the carcinomata.

They probably never occur in early life. Certainly they are uncommon before middle age. After 50 they increase in frequency.

They seem to occur in two chief forms. (1) The glandular type or true carcinoma, originating in connection with the urinary tubules; and, (2) the surface form or epithelioma, springing from the lining epithelium of the pelvis and calyces.

The true renal carcinomata may assume either a nodular or an infiltrating arrangement. Usually they are of a soft cellular variety, although scirrhous and colloid varieties are described. In the most typical forms an adenomatous arrangement is most marked. There is irregular proliferation of the tubular epithelium and other irregular accumulations of cylindrical cells. Degenerative changes seem to be of common occurrence, but extreme cystic formation is not often met with. In size they are generally much less than the sarcomata, and seem usually to develop more slowly. They tend to extend into the pelvis, and hence hæmaturia is usually a marked symptom. They are always unilateral.

Secondary deposits are not generally formed until late.

The papillomata occurring in the renal pelvis seem to be almost always of a malignant character. A number have been met with associated with calculi. They generally appear as very vascular villous growths, much resembling the forms met with in the urinary bladder. As might be expected severe hæmaturia occurs often associated with attacks of pain resembling renal colic. Squamous-celled epithelioma has also been described. Sometimes the pelvic growth leads to the production of a certain degree of hydro-nephrosis.

A number of these growths have been subjected to operation of recent years.

RENAL GROWTHS AND ADRENAL INCLUSIONS.

Hitherto I have not referred to the intensely interesting but most perplexing class of growths which it is supposed originate from included supra-renal tissue. Adrenal "rests" have been found in the peri-adrenal fat, in the tissues around the solar plexus, in the mesentery, in the broad ligaments, and within the kidney capsule.

Is there a relationship between certain forms of kidney tumour and aberrant adrenal tissue? This is answered by many pathologists unhesitatingly in the affirmative. It certainly is a fascinating view but the facts on which it rests are still meagre, and I cannot help but think that the judgment of some is only too apt to be captured by a suggestion so attractive. We have need for diffidence and caution in treading on such new ground.

Still one is compelled to admit that there is undoubtedly a group of renal growths which present a structure closely resembling the zona fasciculata of the supra-renal. Although of adenomatous appearance they have affinities with the sarcomata rather than the carcinomata.

The number of cases on record which may fairly be considered as belonging to this class are probably under 40 in number, and hence it is dangerous to attempt any conclusions.

We are quite in the dark as to the influences which leads a so-called "rest" to take on indefinite growth.

The growths are commonest in males, and usually occur in elderly adults. In 32 cases the ages averaged, males 50, females 45. Tumours considered as belonging to this class have been met with in children. Certainly curious adenomatous growths do occur in young subjects, but I have not been able

to convince myself that they are of adrenal origin. Usually only one kidney is affected. Generally they seem to develop slowly, and long remain local. Secondary deposits occur in many of the cases. Several believed to belong to this group have been removed, and not followed by recurrence.

Some pathologists consider that the so-called endotheliomata and endothelial sarcomata and probably certain forms of angio-sarcoma are closely related to this class.

There is certainly no group of renal tumours needing more thorough investigation than the adenomatous group.

ADRENAL GROWTH.

Closely associated with the consideration of true renal growths are the tumours of the adrenals.

Clinically they are more or less indistinguishable from renal growths proper.

Pathologically they closely resemble some of the growths met with in the kidney, and by a study of the one light is thrown on the character of the other.

The benign or simple growths occur as the so-called "Adenoma." They occur either as (1) multiple nodules or (2) large single forms.

Microscopically they present a structure closely resembling the normal adrenal tissue. There is generally an abundant fine fibrous stroma with epithelial-like cells arranged in masses or in columnar form. Sometimes spaces occur lined with cubical cells, and occasionally presenting papillomatous ingrowth.

Fibroma, lipoma, and angioma have been described. The malignant growths, or sarcomata, I have fully described elsewhere. (a)

In these necessarily condensed remarks, while endeavouring to indicate what has been accomplished, I have more especially desired to insist on what yet remains to be done—the necessity for additional unravelling of the structural details of these growths. Each genus must receive individual study, for since each has its own particular structure it may be reasonably expected that each will present more or less definite signs and symptoms. Possibly the time has arrived when a collective investigation might do much to further our knowledge by the gathering together of specimens, the comparison of cases, the consideration of possible relationships, the correlations of clinical histories with exact pathological features, and the sifting of literary material.

Of this we may be certain that if any true progress is to be made in the early recognition and effectual treatment of renal growths, more precise pathological information must be forthcoming, especially regarding the consideration of structural features in association with clinical manifestations. Only by the accumulation of precise data can we hope to formulate rules whereby the surgeon may know when he may hopefully undertake surgical interference, or when he will most benefit his patient by staying his hand.

TWO CASES OF PTOMAIN POISONING FOLLOWING THE INGESTION OF MEAT.

By G. BURBIDGE WHITE, M.D. Univ. Dub.,
F.R.C.S.I., Dipl. State Medicine, T.C.D.

HISTORY repeats itself in medical as well as other mundane affairs; unfortunately records of ptomain poisoning are of late years too frequent. Not long since I described in these columns cases of severe and continued illness resulting from the ingestion of

(a) "Renal Growths: Their Pathology, Diagnosis, and Treatment." 1896. Chapter XVI., pp. 162-186.

lamb in hot weather, which proved to be New Zealand lamb, which is considered a luxury at the present time. Now I have to record one case of poisoning from New Zealand lamb, and another case from eating tinned corned beef:—

CASE I.—On Sunday, June 4th, 1899, Mr. C. and his family, resident in Dublin, partook of forequarter of New Zealand lamb for dinner at 2 p.m. Mrs. C. again ate the lamb cold on Monday following. The members of the family afterwards suffered from the following symptoms, and in the following order:—First, the cardinal common symptoms were prostration, general malaise, vomiting, vertigo, headache, diminished action of kidneys, and others. Second, they were affected in the following order: Mr. C. was affected on the Sunday afternoon and next Monday; the governess was affected the Monday following and next Tuesday; Mrs. C., Tuesday following (and, it may be added, she was most severely affected); lastly, the children suffered from diarrhoea. The history of the cases and the order in which the different portions of the meat were eaten explain the foregoing facts, thus: Mr. C. was first helped and ate the outside ribs; the governess the next portion; the children got in order the next portions; and, finally, Mrs. C., who carved, ate the neck part. On consideration it will be seen that those partaking of the most exposed portions were most quickly and severely affected, and more is to be learned from the idiosyncrasies of the individuals themselves. Mr. C., who has a most irritable stomach, suffered first; the governess, who is a chronic dyspeptic, was second to succumb; Mrs. C., not dyspeptic, was not affected for three days; and the children, whose power of elimination is so much quicker than adults, were the last to be affected. Mrs. C., who took in most of the poison, was laid up for a longer period and has not yet completely recovered. A careful inquiry as to the articles of the diet previously, and at the time, led to a negative result as to whether the illness was caused by anything else.

At what period of its transit decomposition set in in this lamb cannot be determined, it may have been before shipment, or after arrival in England. The antiseptic gauze wrapper may have been torn, or some such accident. The finger of caution is pointed towards this class of meats, viz., imported dead meat, especially lamb, as a food, and the question as to whether these meats are safe and wholesome food is one that should be solved in the interest of public health.

CASE II.—Mr. H., an English gentleman, æt. 54, passing through Dublin on the night of Saturday, June 24th, 1899, ate for supper some tinned corned-beef, bread, and a little salad, and drank some ale with the supper. Next day, Sunday, I was summoned to see him as he felt very unwell and had not been able to take breakfast. I found he suffered from prostration, general weakness, irritable stomach; he had no headache, but later on he had, physical examination revealed furred tongue, quick, irritable pulse, tympanitis and dilation of the stomach, with feeble cardiac action—the most remarkable sign was to be seen in connection with the skin. An eruption of a patchy character, varying from the size of a finger nail to that of a small plate, covered the trunk and extremities, of a deep purple hue, and very itchy. Next day oedema of the eyelids and oedema of the mastoid and cervical regions supervened, and temperature ranged to 101 degs. F. There was also marked diminution of urine, which was not, however, albuminous. He put his attack down to some salmon, which he had three days before, but on a careful consideration of the food he had partaken of, up to the onset of his illness, there was nothing to the charge of which it could be laid save to that of the tinned meat. Under suitable

treatment and diet, the poison which had evidently gained access to his system was gradually eliminated, and the rash and oedema very gradually disappeared, but, nevertheless, were very persistent, and after an interval of about ten days the patient was pronounced convalescent. Numerous cases of poison by these tinned meats have already been recorded. It seems that there is still room for improved methods of preserving this class of aliments, so as to effectively prevent incipient decomposition, wherein lies the occult danger, as a bad smell is seldom present in this stage to act as a warning, and the taste, if such be present, is generally concealed by condiments, &c.

THE SURGICAL TREATMENT OF FIBROMYOMA. (a)

By PROFESSOR SCHAUTA,
Vienna.

SCHAUTA contributes the result of his personal experience founded on 424 cases of operative treatment of myoma uteri with opening of the peritoneum, in a number of 2,263 peritoneal operations performed by him.

General Indications.—Tumours are only to be treated surgically in cases where all other treatment has failed. When they merely exist without causing pain or any other symptoms it is not justifiable to operate.

Palliative Operations.—Curettage and castration. These should be generally set aside as inefficient and very often dangerous, and only be resorted to in cases of very small intramural tumours that cause no plastic changes in the uterine cavity.

Schauta performed castration 45 times with three deaths, two from interior hæmorrhage, after the ligature had slipped off, and one from peritonitis.

Vaginal Radical Operations.—Removal of submucous pedunculated tumours, or of those with broad implantation, through the dilated cervical canal.

There is little to remark about the first, the way being clearly shown. It is always a legitimate treatment, even in cases where there is evidence of tumours in utero, on account of its absolute freedom from danger and pain, and because hæmorrhage ceases after the ablation.

With broad-based submucous myomata it is necessary to dilate and sometimes to cut open the cervix. Enucleation is only indicated when part of the tumour is born. The operation must on no account last longer than one *séance*, on account of the danger arising from possible sepsis or gangrene.

Interstitial or sub-peritoneal tumours, when isolated, and not larger than a man's fist, may be treated by vaginal oölotomy and enucleation, the bed of the tumour being stitched up afterwards.

This operation forms the transition to intraperitoneal treatment for tumours, which consists in dissection of the cervix, detachment of the bladder, opening of the peritoneal cavity, sections of the capsule, enucleation of the tumour and stitching-up of the wound and the uterine wall. The uterus can also be left alone, or if there is any danger to be feared from secondary hæmorrhage or infection treated extraperitoneally between bladder and vagina.

Vaginal Total Extirpation.—By principle this should be preferred to all other operations for myoma. The suitability for this operation should be determined by the upper limit of the tumour, which should not extend above the umbilicus, and upon whether it can be pushed into the small pelvis; 148 cases with five deaths, of which two could not be considered as result-

(a) Presented to the International Congress of Gynaecology and Obstetrics at Utrecht, August 1899.

ing from the operation, i.e., one from intestinal stenosis, and one case of putrid myoma; of the remaining three, two were lost by secondary hæmorrhage, and one by peritonitis.

Schauta's technique is so far different from the usual method, that after anterior and posterior opening of the peritoneum he stitches their edges to the corresponding edges of the vaginal walls. The broad ligaments are secured by ligatures, and he then amputates the cervix as high as possible. He does not employ forcipressure.

Abdominal Radical Operations. Abdominal Enucleation for the Removal of Pedunculated Myomata by Laparotomy.—Enucleation is called for, only in cases of isolated tumours, not larger than a man's fist; the indication is therefore of rare occurrence. The same is to be said for pedunculated tumours, as they are seldom found isolated, and their removal demands amputation, either supra-vaginal or total extirpation. Schauta performed enucleation 25 times with five deaths of which three were from *embolism* and *pneumonia*.

Supra-vaginal Amputation. Extraperitoneal Treatment of the Pedicle.—Schauta, formerly a partisan of this operation, practises it now only, in exceptional or urgent cases. About the technique need only be mentioned, that amputation of the uterus does not take place, before having stitched the peritoneum of the pedicle, underneath the ligature, to the parietal peritoneum of the lower angle of the wound, as a preventive to infection of the peritoneal cavity by the contents of the uterus. On 78 similar cases, 13 deaths, two from pneumonia, one from fatty degeneration of the heart, and one from rupture of a pyosalpinx with peritonitis.

Intraperitoneal Treatment of the Pedicle.—As an advocate of abdominal total extirpation Schauta only applied three times intraperitoneal treatment of the pedicle, twice with fatal results. He admits the primary advantages of this method, but considers the frequent occurrence of exudation, and the possibility of malignant degeneration of the stump, of far too great importance to be overlooked, and therefore searched for a better method.

Abdominal Total Extirpation.—The only objection to this method is its difficult technique, whilst it may also be considered that the rate of mortality is slightly higher than with extraperitoneal treatment.

Schauta obtained the following results:—On 106 operations, 12 deaths, i.e., 15 per cent. There were, however, but 10 of the number that could be considered as the direct result of the operation, bringing the percentage to 9.4 per cent., the others were due to complications, as paralysis of the vagus, serious anæmia, embolism, &c.

Schauta employs the following technique:—After eventration of the tumour, the broad ligaments are secured on either side by forceps, two on each side; he then makes the incision of the serosa and detaches the bladder as far as the insertion of the vagina, the parametria, quite near the uterus, are clamped and the incision of the uterus made. Two clamps are likewise placed right and left of the lateral vaginal pouches, and the vagina opened right and left. The tumour now hangs to a narrow bridge formed by the anterior and posterior vaginal walls. This bridge being in a similar way secured by two curved volsellæ, the uterus is severed. To the clamps are substituted ligatures, which are not cut short, to be used for drainage, and finally the peritoneum of the bladder is united with that of the posterior vaginal wall. Whether the ovaries should be removed or not, is a question which gives rise to great difference of opinion, and which requires a long course of careful observation in order to be solved.

Schauta is no advocate of *forcipressure*, having lost seven patients on the forty cases, when they had

applied this method to vaginal operations, nearly all the deaths being due to secondary hæmorrhage after removal of the clamps.

Drainage is recommended, as well as in cases of total abdominal extirpation. The supravaginal wound cavity is for this purpose left open towards the vagina, the threads, which are left long, perform the drainage.

CONCLUSIONS.

1. Operative treatment for fibroid tumours is not legitimate except, when they are the cause of troubles that are not to be conquered by other means.

2. Vaginal total extirpation should be considered as the safest, and in the long run, most successful operation. It should be performed in all cases when the tumour does not extend above the level of umbilicus, and when it can be easily drawn into the small pelvis.

3. For large, not easily movable tumours, wholly or partially intraligamentary, abdominal total extirpation should have the preference.

4. Supra-vaginal amputation with intra-peritoneal treatment of the stump, gradually should be set aside in favour of abdominal total extirpation, although the immediate results of the former are sometimes more favourable; it has been proved that there are more chances for absolute recovery, when no part of the cervix has been allowed to remain.

5. In emergency cases, supravaginal amputation with extraperitoneal treatment of the stump, may be, as it affords facility for speedy and absolute extraperitoneal execution, an advantage not to be underrated, in cases of extreme anæmia, asphyxia, weakness of the heart, and suppuration or necrosis of the tumour.

6. Vaginal enucleation of broad based, submucous tumours, either by way of the dilated cervix, or by the vaginal fornix, after anterior or posterior colpotomy, with or without opening of the peritoneum, should be only resorted to in cases where there are special indications. Myomata being generally multiple, it would not be likely that the operation would afford durable results, and therefore cannot be considered as less dangerous than the radical operation, with removal of the uterus.

7. Curettage should be looked upon as an uncertain mode of treatment, neither is it wholly free from danger, and should be limited to rare cases of beginning myomatous development.

8. Castration should be strictly objected to on the ground of its not bearing comparison with the radical operations, with regard to reliability and immunity from danger. In quite exceptional cases, when it is not possible to perform supravaginal amputation with extraperitoneal treatment of the stump, it may now and then be resorted to.

9. It is not to be thought that the methodical use of forcipressure affords the patient advantages superseding the use of ligatures, except in so far, as they facilitate a speedy operation, in typical cases. In cases of emergency or danger their use is certainly to be justified.

10. The full value of drainage of the supravaginal wound for furthering throughout the chances of asepsis, and for the avoidance of exudation, in abdominal as well as in vaginal total extirpation, should be always kept in mind.

11. The question, if removal of the ovaries should be performed, with vaginal or abdominal total extirpation is not yet decided. "Ausfall-erscheinungen" (Climacteric Symptoms) have been observed either way.

If the ovaries are removed they appear immediately, if left back, after weeks and sometimes months.

INTESTINAL ANTISEPTICS. (a)

By BURNEY YEO, M.D., F.R.C.P.Lond.,

Professor of Medicine at King's College, London; Senior Physician to King's College Hospital.

INTESTINAL antiseptics and evacuants have for a long time been in use without the *rationale* for their use being known. The old blue or calomel pill, together with the black draught which dissipated the spleen and the vapours for our forefathers are instances to the point. I intend to consider the subject under four headings: (1) What is the scope of antiseptics? (2) What is the scientific basis for their use? (3) Under what conditions are they applicable? and (4) what are the means of applying intestinal antiseptics? With regard to (1) the medical use of antiseptics is different to the surgical use. The surgeon nowadays aims rather at asepsis than at antiseptics. But in medicine, as concerned with the intestinal contents, asepsis is impossible. We must, if possible, prevent, or at any rate antagonise, auto-intoxication—i.e., intoxication of the organism with the products of digestion. With regard to (2) it must be remembered that certain bacilli are only harmful in the presence of putrefaction or other abnormal condition. The bacillus coli, for instance, is a normal inhabitant of the intestine, and under ordinary circumstances is harmless. If, however, the bowel becomes abnormal in any way owing to catarrh, long-continued constipation, or sometimes injury, the bacillus coli seems to take on a virulent action. When associated with the bacillus typhosus it has the power of intensifying the virulence of the latter. The experiment of Dieulafoy with the bacillus coli when taken from an appendix, the cavity of which had got shut off from the rest of the bowel, and the same organism when taken from the normal mucous membrane of the bowel, show that the former is virulent, the latter not so. As, then, the virulence of intestinal bacteria depends upon their environment, so by modifying that environment it is reasonable to suppose that we can modify their virulence. With regard to (3) intestinal antiseptics are indicated in gastric catarrh and fermentative dyspepsia. Grangé recommends in cases of summer diarrhoea the use of plain boiled and cooled water. He claims that the use of this dilutes the toxins. There are many other conditions to which fermentative dyspepsia and auto-intoxication give rise. Such are dyspepsia, chest pain simulating angina pectoris, vertigo, aphasia, and anæmia. Even pernicious anæmia had been considered by some observers to depend upon some toxin which exerted a hæmolytic action. There are three other diseases in which the use of intestinal antiseptics is rational—namely, cholera, dysentery, and typhoid fever. Of the first two I have had no practical experience, but with regard to typhoid fever I have for some years advocated and practised the use of intestinal antiseptics. Typhoid fever often exhibits symptoms of being due to a mixed infection, and this may explain the extraordinary variations in the severity of cases. I can recall instances in which the use of a chlorine and quinine mixture given every two or three hours has been attended with most marked results for the better in cases of typhoid fever. So, also, in some cases of indefinite febrile affections accompanied by rise of temperature, furred tongue, and foul-smelling stools the use of thymol by the mouth, together with irrigation of the large bowel by eucalyptol, olive oil, and soap-and-water administered in the knee-chest position, had rendered the patients well. I am not able to say to what exact disease this condition was due, but I think that whether the original infection had been by typhoid fever or influenza that the con-

dition which I was called upon to treat was due to the action of the bacillus coli in an abnormal environment. With regard to (4) the various intestinal antiseptics are: water boiled and cooled, calomel and salines, both of great value in the early stages of typhoid fever. Salicylate of bismuth and carbolic acid are both useful. As to the latter I remember a case published recently in the *Lancet* by Dr. G. Williams, where a patient suffering from typhoid fever took by mistake one ounce of carbolic acid. He had, of course, to be treated for the toxic effects, but recovered from them with his typhoid fever symptoms much lessened. Salol is very uncertain. Eucalyptol and thymol are both good and irrigation of the large bowel in such cases as I have mentioned was a necessity. Patients, especially in typhoid fever, must not be overfed. I would conclude with a warning against the production of the modern manufacturing chemist who sets up to teach the clinical physician.

ON THE PREBALNEAR TREATMENT OF HEART DISEASE,

AND ON THE
USES OF THE INHALATION OF CARBONIC
ACID IN CARDIAC DYSPNŒA AND
ANGINOID PAIN (a).

By WM. EWART, M.D.Cantab., F.R.C.P.Lond.,
Physician to St. George's Hospital, London, and to the Belgrave
Hospital for Children.

THE treatment carried out during the last two years consists in the inhalation of carbonic acid for varying periods (from five to twenty or thirty minutes) three or four times daily in cases of broken compensation with heart hurry, cardiac dyspnœa, angina, or pain, &c., and in cardiac neuroses or neurasthenia, at stages when the Nauheim treatment is inapplicable. Carbonic acid, as is well known, being harmless when inhaled for limited periods in proportions less than 15 per cent., relief to the heart and respiration and to the subjective distress is gained without any risk, the action of the remedy being mild as well as immediate, and the after effects of any overdose (a contingency which has not come under observation) being purely transitory.

By reason of this mildness and of the ease with which the amount can be regulated (by watching the bubbling of the gas through the water of a wash bottle) there are hardly any cases of cardiac distress in which it may not be tried; and there have been but few in which it did not afford relief either when inhaled alone or in association with oxygen.

As implied by the name, the treatment is in many cases a preliminary to the Nauheim treatment, for which it prepares the way when used independently, or in association with medicinal adjuncts. It is a test for the suitability of doubtful cases for a course of the baths, and for some cases which are absolutely unsuitable for the latter, it is a valuable substitute and instalment of treatment. When cases have so far improved as to be submitted to the Nauheim treatment, the inhalation as a separate measure becomes superfluous, carbolic acid continues to be inhaled in a modified way in connection with the baths. The action exercised upon the rate and strength of the pulse being relatively slight the inhalation of CO₂ is specially welcome in the treatment of aortic regurgitation, of mitral stenosis, of cases with four valvular murmurs and in anginoid conditions or angina, where digitalis is either inad-

(a) Abstract of paper read before British Medical Association, Portsmouth, August, 1899.

(a) Abstract of a paper read in the Section of Medicine at the Annual Meeting of the British Medical Association, Portsmouth, August, 1899.

missible or subject to caution. Notes of some of the many cases which have been treated with benefit, including cases of mitral regurgitation, of tricuspid regurgitation with cyanosis, and of dilatation of the right side of the heart, &c., were submitted with the paper.

The Nursing Problem.

NURSES OF THE LATEST FASHION.
A.D. 1899.

PROFESSIONAL EXPERIENCES IN SHORT STORIES.

By FREDERICK JAMES GANT, F.R.C.S.,
Consulting Surgeon to the Royal Free Hospital.

V.—NURSE GOSSIP AND SCANDAL.

THE first-named species of nurse may not be a distinct character, apart from some other nurse-forms of "the latest fashion"; but she is specially distinguished by her confidential communications—that, "they do say"—of others; whatsoever probably she knows her own self to be—as if in them.

Nurse-scandal, sometimes taking form as the "obscene nurse," the latter species is more often distinctly specialised, and more surely a disclosure of the woman's own depravity.

But an unbridled tongue is a traitor to more than its possessor. A high authority on nurses and nursing, Georgina Scott, late matron of the Sussex County Hospital, writing on the golden beauty and value of silence, remarks that "Perhaps no one is more behind the scenes of life than is the sick-nurse; perhaps no one else comes into such close contact with the sacred and secret concerns of life as she does. Doctors, lawyers, and clergymen have many revelations, many insights into the recesses of family secrets. They know of sins and strange complications little dreamt of by the outer world. Still, their visits are limited compared to those of a nurse, who spends day after day and night after night in the house of sickness, hearing much and seeing more than many may at first sight suppose. Much is told to the doctor, lawyer, and clergyman; but the sick-nurse has even more confidence given into her charge. She can see, as well as hear, many details of many a sad and complicated life. Nurses should keep these confidences as faithfully as they would have their own private affairs treated. They must hold all such knowledge gained in their work as sacred, covering it with *silence*."

"Again, it is hardly good taste to talk to patients of our (nurses) professional work, or to give them details of cases and their treatment; nor is it honourable to discuss the merits of one medical man compared with those of another. Recluses we may not be. Careful conversation, or discreet silence need not strip us of sympathy, nor make us lack interest in the joys and sorrows of our fellows creatures. But secrets, once discussed, must take their course; there is no calling them back again; penitence has no power to make good a broken faith. Regret for hasty and foolish words, sorrow for gossip and scandalous conversations, remorse for having given into the confidence of another the secret thoughts of our own soul, come to us alike; and in the darkness and stillness of the night, with no one to see or hear, we have blushed and then grown cold with the recollection of the weak and erring utterance of our tongue."

VI.—MASSEUSES.

Quite modern medicine has demonstrated the remedial efficacy of friction, rubbing, and kneading various parts of the body in the treatment of diseases to which they are subject. This method of mechanically relieving pain, restoring muscular power and movements, and of regaining sensibility—in many nervous and muscular affections, especially, has received the name of *massage*. The advance of women all along the line of human progress, and notably in the march of medicine—like a huge wave

on the ocean of our social life—has brought up a considerable number of women-masseurs, whose profession is *massage*.

When properly trained in the school of medicine, it cannot be doubted that such women are valuable *adjuvants* to the practitioner of medicine and surgery. The manual dexterity, combined with firmness and lightness of touch, with which the hand of woman is endowed, and when perfected by practice, will enable any such feminine manipulator to exercise a mechanical art more effectively than most male competitors. And, if in addition, a naturally womanly character, coupled with the delicacy and refinement of culture, moves with the hand in the performance of her duties, the masseur-woman will be a valuable member of Society.

She is akin to the properly qualified nurse, in her professional relationship; and like her is fitted to attend private cases (of massage) under supervision of the medical practitioner; or the two callings may be united.

It is easy, however, to imagine the woman, the lady-masseur or masseuse as she styles herself, whose untrained hand, and defective tone of moral character, would reverse the picture of the rightfully named masseuse. Which may be most harmful, her hand or her heart, when its resources are brought into play in private practice?

The public, in many cases, could answer this question from personal experience of the masseur-woman, and the unpublished memoirs of family life. The disclosure would traverse most of the careers of which glimpses have been seen in the private nursing of the untrained and uncertificated, unregistered; or some other "Nurses of the Latest Fashion." If we could not track "Satan in Petticoats" in some portions of her dark life history, we might certainly discover the "husband-huntress and trapper"; or find the "husband-seducer masseuse"; or encounter the "breach-of-promise lady-rubber." She rarely appears, perhaps, as the "dangerous widow"; nor does the said lady ever belong to any "religious order of women." Nor can the species of woman known as masseuse be classed with the "unfortunate" nurse, who mostly commences her career as a hard-driven exile from home, more sinned against than sinning. The fair but frail masseuse is a distinct species, having a double occupation in a life which lends itself to both. In her proper professional capacity the lady masseuse passes for a sort of "doctor-nurse."

Nigh round the corner of a fashionable square at the West-end of London, where luxury and rank smile, each admiring the other's beauty, stands a small house which, as a lean-to to the adjoining mansion, seems to be an offshoot from that abode of bliss—not perfect, of course, as no human condition can be.

A lady-rubber took the useless small tenement for one year's trial in the practise of her art. Painted of a cream-white colour, like the tenant, it looked a pretty little box, with its large brass-handled door, and the pure white lace curtains drawn across the window, except at an interval formed by two blue satin sashes, which presented an almost complete blind to any intrusive gaze over the railings of the little area. This room was the lady-masseuse's first sanctum: a recess at the back, without any window, and which was furnished with a luxurious couch, provided accommodation for any elderly or crippled patients to derive the benefits of rubbing without having to ascend the stairs to a bedroom above. The lady herself rivalled the remaining upholstery in her dress, that of a nurse, but more expensive, if not more becoming.

She distributed her "card" all over the neighbourhood, announcing herself "Miss —, Masseuse, P— Place. Her hours, "at home" in the morning, 11 a.m. till 2 p.m., "afterwards by appointment," as she had her out-patients to attend at their houses. She drove a brougham hired from the livery stables attached to the stabling of the square.

Occasionally, some elderly gentlemen, or it may be a lady, called, and the hall door having been opened by a well-appointed maid, the patient was taken in and done for by the massage treatment. Each sufferer's rubbing in the hands of this skilled manipulator, as she seemed

to be, would occupy an hour, more or less, ere the fee, 7s. 6d. or half a guinea was duly earned; and as a course of treatment was generally recommended, the practice was not unremunerative. So massage, in hands which the owner knew how to work, might have grown into a flourishing concern.

But, besides the patients who came and went, the domicile was visited by others who might have been grateful recipients of the treatment, who called just to show themselves as trophies of the system which had restored them to health and strength; there were gentlemen in the prime of life, whose vital powers needed no replenishment; they bore the steady-going manners of middle-aged married men, for whom loving eyes would watch their coming home to dinner, and look brighter when they came; and besides these "patients" there were elderly clubbites, who called on the way to their home. All these visitors to the lady masseuse called in hansom cabs—never in private carriage—and they never drove up to the door, but alighted round the corner in the square. So altogether a pretty deal of business went on in the white cream-coloured little domicile; the lady at home had her hands full of subjects for rubbing, &c.

Whisperings from the wagging tongues of neighbours began to report their suspicions. That massage cases were treated by her in her elegant sanctum, and in the bedroom overhead, there could be no doubt from the testimony of those who had undergone the cure, and who moved in the best society. Still the whisperings grew into something like a complaint that the house was a sort of nuisance. Then the attention of the Vestry was directed to the business of the fair masseuse. The Board were very reluctant to interfere, unless some definite complaint was brought to their notice; and by a written application, signed by some half-dozen neighbours. They, however, declined the invitation. Then the Board sent two vigilant policemen; but they saw—nothing.

The lady having heard, somehow, of some imputation against her skill as a masseuse, or her manner of using the treatment, she threatened any informant with legal proceedings. She would go instantly to her lawyer, who knew her well, or as well as any man can know a woman, or one of a kind never to be known.

The wave of rumour still rising, and spreading; or say, the fire smouldering, at length broke out into a blaze; until the house, and the lady occupant would have been sacrificed to the clamour of her neighbours in the side street. The noble inmates of the house immediately adjacent dwelt serenely unconscious of *their* neighbour; two young daughters sitting in the conservatory, separated only by a partition wall twixt them and the massage couch, and bed-room above; could they have dreamed of anything wholly outside the happy experience of innocent young womanhood?

The lady masseuse was about to flee away from her uncongenial surroundings, and open a *modest* establishment elsewhere, in some fashionable watering-place, the resort of London's rheumatic, or nerve-worn, invalids, and other break-downs, in the battle of pleasure and pain, among those who live too much in the charms of Society and its atmosphere.

But the lady's career, in her present locality, had now reached its climax. The landlord was informed that the house was not so clean and pure as it looked. He knocked at the door, and an unsuspected visitor was instantly admitted by the maid, as probably another case of her mistress's art. He passed the lower sanctum, and made direct for the bedroom. There lay the lady masseuse, and there also what he saw he believed. Within an hour the tenant was ejected; her luggage following this accomplished feminine-rubber up to date.

VII.—THE MIDWIFE AND THE MONTHLY NURSE.

In concluding the present series of representative "Nurses of the Latest Fashion," there yet remain several other types whose living portraiture lies in a state of suspended animation in my *escritoire*.

Thus, only to mention the "Night-brawling Midwife," with one of her nurse-girls of the same breed; the one holding a "three months' certificate" of qualification

from a certain lying-in hospital; the other, "one month's qualification" for her duty. Here is an authoritative description of the latter nurse-species, as expressing her personal qualities.

"She has not in her the making of a nurse; she is utterly selfish and cruel. Whenever she would have a holiday she would leave her charge in a dying state to keep her appointment with her man, who is waiting round the corner."

She sallies forth, wearing an unfortunate dress from head to foot. Having doffed her nurse attire, see her thus: Hat surmounted with huge white ostrich (?) feather, &c., purple blue cloth gown, bespangled with silver filigree; an open, frilled chemisette, arranged to disclose that which the wearer affects to conceal. A front longitudinal fold in the dress, buttock-tightened, guides to her conformation below; while nameless shoes with buckles invite attention to her ankles.

This midwife-nurse returns to her patient too late for duty; and being shut out (to call again in the morning), she reappears, armed with the aforesaid brawling midwife. After repeated thundering rapping at the street-door, accompanied with bell-breaking ringing, the midwife's voice is heard under patient's bedroom. The husband, alarmed for his poor wife's safety—and himself a great sufferer, as she with the hat and feather well knows—the husband in his night dress is now at the dining-room window, shutters and window fly open, a crowd with a hundred midnighters, headed by a policeman (388 F.) meet his dazed eyes. "This job"—shouts the midwife—"will cost you some pounds, besides a good hotel bill for this girl's bed and breakfast" (at the house of the deliverer from the pains and perils of child-birth).

A small fee—half-a-crown, ready money—at once sufficed to discharge all the husband's liabilities, and silence the *threats* of this lying-in woman.

NOTE.—this glimpse of a midwife, and of her girl, both up to date, will supply any additional evidence touching the Registration of Midwives, for the next deputation to lay before the Lord President of the Council.

PARIS, August 26th, 1899.

FIBROMA OF THE UTERUS.

M. DOYEN read a paper before the International Congress on Gynecology on the treatment of uterine fibroma. Those tumours, he said, should be removed each time that they increased in volume and that they produced grave accidents—phlebitis, albuminuria, intestinal occlusion, malignant degeneration of the uterus, far from being counter indications, constituted, on the contrary, imperative indications to operate. Ablation of an isolated tumour, either through the vagina or by laparotomy, with preservation of the uterus, was only indicated in very rare cases. Hysterectomy should be performed when the fibromata were numerous. When the uterus was mobile and could be easily drawn forward, the operation might be done through the vagina. The same method should be followed in case of great obesity which rendered laparotomy particularly difficult. In every other case the abdominal operation should be preferred.

Since the speaker employed the *écraseur* and substituted ligatures for forceps a *demeure*, he had operated fifty-two cases of hysterectomy for fibroma, of which twenty-seven were through the vagina, all successful, while of the remainder he only lost one case, that of a patient who had suffered from phlebitis of the lower limbs and from appendicitis.

M. Villars said that he believed that certain fibroma should be respected, for it was abundantly proved that those tumours were frequently well supported.

Dr. Giles (London) thought that it was not necessary to operate tumours provoking no morbid manifestation. On the other hand hæmorrhage, compression, degeneration of the tumour necessitated radical intervention. Palliative treatment was not only useless but dangerous.

CÆSARIAN OPERATION.

M. Pinard established a comparison between the Cæsar operation and symphyseotomy, craniotomy and artificial delivery.

The abdominal section, he said, was a simple operation, easy to execute and the dangers of infection and hæmorrhage were greatly diminished, thanks to the application of antiseptics and of sutures. As to the child, it was placed beyond the reach of all traumatism. While the Cæsar operation permitted the immediate termination of the delivery, section of the pubes with consecutive dilatation of the pelvis constituted a preparatory intervention permitting the child to traverse the outlet without having to struggle against the osseous wall. The soft parts, vagina and vulva, should be afterwards dilated so that the child could be expelled or extracted *per vias naturales*. Symphyseotomy was also an easy operation, as the statistics of the Baudelocque Clinic proved, for out of 100 cases practised between 1892 and 1899, 88 mothers recovered and 87 children were born alive. Twenty-two of these women became pregnant for the second time, and sixteen were delivered naturally, while the remaining six had to submit to a second operation. Craniotomy in which the child was considered as a foreign body was rarely sufficient in itself, crushing and dislocation of the head were nearly always necessary. Out of eighty-one craniotomies practised in his wards within the last fifteen years, seventy-two of the patients recovered. Premature artificial delivery, which consisted in the interruption of the pregnancy at a period where the fœtus is viable and at the moment when its dimensions do not exceed that of the pelvis, should suppose a precise knowledge of the age of the pregnancy, of the degree of the narrowness of the pelvis, and of the dimensions of the fœtal head. These desiderata were rarely realised in clinical practice, if one were to judge by the best statistics by which were shown that the fœtal mortality exceeded 30 per cent.

As regarded the indications and counter indications, the principle should be laid down that the accoucheur should be a doctor in all his acts; the obstetrician had always before him the duty to protect the child as well as the mother. Applied to the therapeutics of pelvic deformity, that doctrine excluded provoked delivery as well as embryotomy on the living child. If before the era of antiseptics, at a period when the Cæsar operation or symphyseotomy were usually followed by death to the mother, premature delivery had been recommended and adopted, it was no longer the case in these days. When a woman cannot be delivered on account of malformation of the pelvis, and the child was living, two operations alone were possible, dilatation of the outlet or abdominal section.

M. Pestalozza said that premature artificial delivery

was without danger to the mother when the rules of antiseptics were scrupulously observed, but it exposed the child to several accidents immediate or remote. It was particularly indicated in young women in their first confinement.

Symphyseotomy should be reserved for those who had borne several children on account of the inextensibility of the tissues in the primipara.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, August 25th, 1899.

GUAIACOL CARBONATE AND CREOSOTAL IN THE TREATMENT OF DISEASES OF THE RESPIRATORY PASSAGES.

FROM the proceedings of the Tuberculosis Congress held in Berlin, we note a paper on the above-named subject by Dr. Fr. Holscher, of the Dreikönigen Hospital, Mülheim.

Dr. Holscher, who is physician-in-chief of the hospital named, claims that these two allied remedies have already taken the first place in the treatment of all pulmonary diseases. A dietary rich in albumenoids is desirable, as the guaiacol and creosote absorbed from their carbonates effect an increase in the decomposition of the albumens of the body. The remedies further this rich dietary by increasing the appetite and stopping abnormal putrefaction processes.

In giving full doses of these remedies, the urine is often observed to become dark, but this it is claimed is no sign of any poisonous action.

The remedies are said to effect a largely increased body weight, disappearance of fever and night sweats after several weeks' treatment, diminution of cough and expectoration, and their final disappearance. The tubercle bacilli are also said to diminish in number. Creosotal is also extremely useful in pneumonia, causing a fall of temperature within twenty-four hours of its first administration; if the drug is continued the temperature is said to remain normal.

MODERN MYOMA OPERATION.

At the Medical Society Dr. Czempin read a paper on this subject, prefacing his remarks with the observation that operations for myoma were not looked upon with great favour by the practitioner, and that this view was partly due to an over-estimate of the harmlessness of such tumours; and to the possibility of their spontaneous retrogression after the menopause.

As regarded the latter point, he observed that among his seventy-two cases of operation, eight of them were in women between fifty and sixty years of age.

Palliative treatment was insufficient. Curettement of the mucous surface, which was very proper in hæmorrhage from myoma, gave good results frequently, but he had had two disagreeable experiences.

Operations were of two kinds, one in which the myoma was removed and the uterus left, and the other in which the uterus was removed along with the tumour, and the operation for either form might be vaginal or abdominal. Dilatation with laminaria, and attempts on the tumour by this route he rejects, and if adopted, everything should be in readiness for proceeding by the abdomen in case of need, as where the uterus wall is per-

forated or torn. In twelve of his cases the tumour was partly expelled. In case of firmly seated myoma in virgins Dührssen had proposed a new way. The uterus was separated from the bladder. After carefully ascertaining the exact site of the tumour it could then be cut down upon and enucleated. The wound was then closed. He showed a preparation obtained in this way. In cases of multiple tumours, all of which could not be removed vaginal total extirpation of the uterus was called for. The *morcellement* invented by Péan, of Paris, and introduced into Berlin by L. Landau, was a distinct advance. The speaker had, however, been less fortunate with this operation, which demanded great dexterity. The patient died of sepsis from a misfortune occurring through tearing out of the vulsellum forceps. Since then he had abstained from *morcellement*.

The abdominal method could be either conservative or radical. In six cases he had cut down upon the tumour, shelled it out, and closed up the wound with sutures with a good result. Up to a few years ago the mortality of hysterectomy for myoma was 30 to 33 per cent. Using all the modern means for prevention of sepsis he had operated in eighteen cases with seven deaths. Martin extirpated the uterus along with the tumour from the abdominal cavity. This was the most ideal method; it afforded the safest technique, avoidance of accident and rapid recovery. He had in this way operated twenty-two times without a death. The vessels were ligatured or clamped, the tumour rolled out, the round ligaments cut and ligatured. The bladder was treated next, an anterior flap was formed on the uterus, and the bladder separated. If the bladder were now pushed away the uterus would only have on it the remains of the ligaments. Some authors took no notice of the uterine artery. Landau always ligatured and severed it. The speaker always sought for it and ligatured it. After cutting through the vagina and removing the uterus, nothing was left but an anterior and posterior flap which should be brought together and united by suture. The results of this method were positively brilliant. Care must be taken in selection; tumours growing in the broad ligament, and which necessitated extensive, opening of the connective tissue, often did not do well on account of infection. In the speaker's five cases general infection of the peritoneum took place in three. He had never seen good results from castration; even in old women the hæmorrhage does not quite cease.

His conclusions as a whole were: The prognosis in case of myoma when no bleeding was present was upon the whole favourable. Myoma should not be treated lightly in view of possible malignant degeneration, and of the troubles that frequently attend them. On the other hand, operation affords a better prognosis than it did ten years ago, especially the new vaginal and abdominal total extirpations gave ground for favourable results. One could, therefore, persuade patients to have the operation performed before they fell victims to permanent illness that always follows in the wake of typical hæmorrhages.

VOMITUS GRAVIDARUM PRENICIOSUS.

Hyperemesis gravidarum, according to Sajaitski, *Deutsch. Med. Zeitung*, 50/99, is not a neurosis but a simple reflex phenomenon caused by irritation of the peritoneal coating of the uterus from enlargement of its cavity. It occurs in cases in which the lower segment of the uterus does not increase in size *pari passu* with

the upper portion, where the hyper-extension is too rapid, as in the cases of hydatid mole, hydramnios, &c., or when some hindrance to normal development is present, as from chronic metritis, interstitial or submucous myoma, &c. In addition to the local irritation of the peritoneal covering of the uterus, which is always the original cause, increased irritability of the nervous system contributes largely to its occurrence.

As regards the infrequency of the affection the author observes that the wombs in which it would be likely to occur are generally sterile, and that many of the diseases that cause it improve on pregnancy taking place.

The treatment of hyperemesis gravidarum is as varied as its ætiology. Most of the remedies employed or recommended for the disease are useless, the sole remedy lying in the appropriate local treatment of the affection of the womb that causes the vomiting. If this does not succeed nothing remains but to interrupt the pregnancy. In some desperate cases this radical measure takes place spontaneously. When it has to be resorted to artificially it is without danger, if carried out in accordance with the principles that govern modern surgery.

PROFESSOR AUG. BIERE, of Kiel, gives an account in the *Zeitsch. f. Chirurg*, of attempts he has made to produce extensive areas of local anæsthesia by injecting cocaine into the spinal canal. His attempts were made on himself, his assistant, Dr. Hildebrandt, and five patients. Quincke's lumbar punctures of the cord were made when the cocaine solution was injected, the largest amount given being .01 grm. The result was said to be mostly satisfactory, or rather satisfactory in one direction. The local anæsthesia desired was produced, so that the whole of the lower half of the body was rendered insensitive to pain, and in this condition major operations were performed on his five patients, but the bye effects were by no means satisfactory. Even with the doses given headaches were caused, which lasted a whole week, whilst nausea, vomiting, and giddiness were so severe as to compel a horizontal position in the bed. Whether his intended further investigations on animals will shed further light on the subject is rather doubtful. Enough has been determined to show most surgeons that the game is not worth the candle.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, August 25th, 1899.

"HEILSERUM."

IN the last two sanitary reports issued by the Imperial Office the kingdom of Galatia has been represented as only using the anti-diphtheritic serum in 16 per cent. of the cases, which was given as a reason for the high death-rate in that country.

Latest reports prove that the serum has been more widely used than in other places and are pointed to as examples of the "heilserum." The complaint now is that the serum has been indiscriminately used, which accounts for the high death-rate! These revelations have all been disclosed since the Kassowitz discussion in the "Gesellschaft," when this country was jubilantly pointed to as conclusive proof of the efficacy of the serum. Raczyński (who is an authority

on diphtheria) contributes an article to the "Przegląd lekarski" to show how difficult it is to diagnose a truly diphtheritic case from an ulcerous process in the pharynx, and relates how every clinical feature was so well marked in this case, that every expert declared it to be a genuine case of diphtheria—even the bacilli diphtheritically proved the case to all observers, and the serum was used. Raczyński cultivated the alleged bacilli and found them nothing more than those met with in any case of angina sclerosa!

From this he reasons that many of our so-called cures accomplished by the use of serum, are fanciful and not real. He is inclined to lean more on clinical facts than bacteriological examinations for a differential diagnosis.

DUSTALS OR GUAIACOL [CARBONATE.

The drugs prescribed for tuberculosis are now so numerous that the more scientific must resort to feeding on air alone under the shadow of a big company concern. Still there are a few who cling to the real article yet and deprecate the company promoter as a charlatan. Eschle confidently believes in attacking the disease internally and locates his operation to the correction of the alimentary canal. Some believe in the treatment of our ancestors, others are content with disinfecting the lung, others again would attack the blood, while Eschle assures us on scientific proof that no treatment of tuberculosis can be successful that does not aim at the first cause—viz., the changes that takes place in the bowel. He has devoted several years to the examination of the carbonate of guaiacol (Duotals) and concludes that it is the most effectual disinfectant of the alimentary canal extant and therefore an antidote for tuberculosis. The advantage of Guaiacol is that it plays a double part in disinfecting the blood as well as the contents of the alimentary tract by simply increasing the dose till the drug is eliminated by the rectum, which can be accomplished without danger, detriment, or any disadvantage to the patient. When given in small doses the drug is absorbed in sufficient quantity to disinfect the blood, but the bowel is not completely aseptic till the drug is passed unchanged.

Cures in abundance are adduced to prove the correctness of Freund's theory long since announced that the low state of nutrition in consumptive patients is due to the decomposition usually present in the bowel which forms the pabulum and induces the growth of the bacilli in all tuberculous conditions.

TETANUS AND SERUM INJECTIONS.

Leyden relates an interesting case of a woman, æt. 29, who fell on the cellar steps and produced an abortion, which was followed by tetanus on the tenth day. On the sixth day of the disease she was taken to hospital, where a subdural injection of 1.0 gramme of Behring's serum was made, along with one subcutaneous injection of 2.0 grammes of Tizzoni's serum. With these injections 0.1 of morphia and 2.5 grammes of chloral were given during the first 24 hours. In the second 24 hours after admission a subcutaneous injection of Tizzoni's serum, consisting of 3.0 grammes, was administered. On the third day two subdural injections of 0.75 gramme of Behring's serum were injected. On the sixth day 2.0 grammes of Behring's serum were used.

The subdural injections were borne favourably although the temperature rose very high. The patient

is certainly better. Though Leyden considers this a success he is unwilling to speak in favour of the treatment.

INFECTIVE CHARACTER OF ARTICULAR RHEUMATISM AND ITS CONNECTION WITH CHOREA.

Wassemann and Malkoff relate the history of a young woman, æt. 19, who was suddenly attacked with chorea at the close of a severe illness from articular rheumatism.

Shortly after the chorea commenced she became delirious, the temperature rising to 41.2 degs. C. (106.16 deg. Fah.), and subsequently collapsed and died.

A few hours later the post-mortem revealed general hyperæmia of all the internal organs with a fine endocardial deposit on the mitral valve and very recent parenchymatous nephritis. Nowhere was pus to be found. In the blood, brain, and cardiac valves a streptococcus was present, which, when cultivated and injected into animals produced high fever and multiple joint affections mostly ending in death.

This seems to be the first clinical testimony of demonstrating a micro-organism in chorea immediately after rheumatism and its affinity with chorea.

South Africa.

CAPE TOWN, Aug. 12th, 1899.

FALSE DEATH CERTIFICATES.

THE case of Dr. Anthony, the American sanatorium practitioner referred to in my last communication, who was charged with giving certificates of death for the purpose of covering one Tate, an American negro, convicted of illegal practice, was decided at the late session of the Supreme Court. It was made clear that Dr. Anthony had, in several cases, given certificates for cases which had been attended by Tate, but had not been seen by himself. In defence, however, it was urged that these cases being coloured children, and Dr. Anthony doing a large dispensary practice among that class, he could not be expected to remember the cases for identification, and that he had been under the impression that he had seen them. In support of this it was sought to prove that medical men in the Colony are largely in the habit of giving certificates for cases they have seen only once, and that perhaps a considerable period before death. A number of certificates given on these lines by medical men in the neighbourhood were adduced in evidence, and this view weighed with the jury, and the prisoner was acquitted. It is only fair to mention that all medical men find great difficulty in fulfilling the strict requirements of the Registration Act, especially those who practice much among the lower classes, or do out-patient work at hospitals. The callousness of many of the colonial people, white as well as black, about the ailments of their children is remarkable, and they constantly have recourse to the medical man solely for the purpose of relieving themselves of legal responsibility. A child is suffering from bronchitis or gastro-enteritis. It drags on without help for some time; then the parent takes it to an out-patient department or to a consulting room. It is prescribed for, and despite the warnings of the medical man, that is the last he sees or hears of

it until, perhaps, three weeks afterwards somebody turns up, says a child is dead, and that a certificate is wanted. Prolonged inquiry and search in your case book (if you have one, which is too often not the case) elicits the fact that on a certain day a child with a particular name was attended for such a disease. You cannot in such a case give a certificate that is worth anything, and yet it is difficult to refuse. The general practice, however, is to decline to sign the regulation certificate, and to give a note stating the facts, which the registrar may or may not accept, as it pleases him. As a matter of fact, some, at least, of the "certificates" quoted in defence of Dr. Anthony were simply these informal letters, and it was unfair to the prosecution that this was not stated, and grossly unfair to the writers. The local branch of the British Medical Association has appointed a committee to go into the whole of the case, as it is felt that, apart from the certificate business, grave suspicion of flagrant "covering" lies against Dr. Anthony.

FAILURE OF THE NEW MEDICAL BILL.

The Premier's amended Medical and Pharmacy Bill, from which much was hoped, has proved an abortion. Its most important clause, one stating that the fact of a man being a licensed chemist and druggist should be no defence against a charge of illegal medical practice, has been abandoned in deference to action taken by the chemists, and now we are face to face with the extraordinary anomaly that whilst the "practice" not merely the assumption of a title implying the right of practice, of medicine, is illegal for everyone else, a chemist can practice medicine to his heart's content. In deference to the same trade, a provision insisting on every shop being under the "constant" supervision of a licensed chemist, has been altered by substituting "bona fide" for "constant." Altogether the Act now contains only one provision of any importance, the imposition of a penalty for wilful uncleanness or neglect on the part of all persons who attend midwifery. Under the old Act, the medical man or the licensed midwife was subject to punishment, the unqualified woman could do what she liked. It is remarkable that only one medical member of the House spoke on the Bill, and he very feebly. As a matter of fact, although we have quite a large proportion of our fraternity in the Legislature, they quickly lose all fellow-feeling with the profession. Perhaps it is not to be wondered at. As a medical legislator said to me the other day, medicine in South Africa, whatever it may be elsewhere, is not the sort of thing to command the devotion of any man of intellectual calibre and honourable instincts.

THE WAR SCARE AND THE MEDICAL PROFESSION.

The Medical Congress which was to have been held here in September, has been postponed to next year, on account of the war cloud hanging over the country.

NURSING AT THE CAPE.

The Medical Council has lately commented in very strong terms on the lack of training given to nurses at the New Somerset Hospital. At the last examination not one nurse got near half marks, and this is not to be wondered at when we are told that the only training they get is obtained from the Matron.

The Operating Theatres.

CHELSEA HOSPITAL FOR WOMEN.

SEPARATION OF ADHESIONS AND VENTRO FIXATION OF THE UTERUS IN A CASE OF CHRONIC RETROVERSION WITH FIXATION.—Dr. ARTHUR GILES operated on a married woman, æt. 40, who had been under his observation for nine months. Her symptoms were chronic pain and menorrhagia. When first seen the uterus was found bound down in a position of retroversion. A course of treatment by means of glycerine tampons and vaginal douches failed to lessen the immobility of the uterus, and the symptoms persisted. She had been curetted four times at different hospitals, but these procedures had not diminished the menorrhagia. In the opinion of the operator, therefore, the bleeding was due not so much to a pathological condition of the endometrium as to the fact that during menstruation the normal uterine contractions were interfered with by fixation. In view of the failure of palliative treatment Dr. Giles advised freeing the adhesions and ventro-fixation of the uterus by abdominal section. This operation was eventually carried out after a preliminary curettage. On opening the abdomen the fundus was found lying in the pouch of Douglas, and firmly attached there by adhesions, the appendages were likewise bound down, but were otherwise normal. With a little difficulty the uterus and appendages were freed and brought up into normal position. By means of two silkworm gut sutures passed through the anterior surface of the body just below the fundus the uterus was attached to the margins of the abdominal incision, the suspensory ligatures passed through peritoneum and fascia on each side. The wound was closed in three layers. Dr. Giles pointed out that the alternative to the treatment here performed was simply to let the patient continue with her symptoms unrelieved. As regards other operations for the purpose of curing uterine displacements he remarked that they would not have been applicable in this case, for instance, Alexander's operation was only practicable when the uterus was free because traction on the round ligaments would probably result in their rupture when the fundus was held down; vagino-fixation had its advocates, but he thought that especially when adhesions were present it was better to operate through the abdomen partly in order to more clearly see the condition of the appendages, and partly in order to work by sight as well as touch in the freeing of adhesions. Unless the separation were carried out in such a case with the greatest care, there was considerable risk of injury to the rectum or to the sigmoid flexure. With regard to the question of the influence of the operation on subsequent pregnancy, he said that many cases had now been reported in which such pregnancy had gone on normally to term and ended in natural labour; this result was favoured by passing the uterine stitches through the anterior surface rather than through the fundus. When passed in the latter position the uterus was hindered from rising into the abdomen in the first half of pregnancy, and miscarriage might occur. Theoretically it might be supposed that the attachment of the uterus in its new position would lead to bladder disturbances, but this was not found to be the case in practice; evidently the bladder readily adapted itself to its new conditions and distension took

place laterally rather than vertically. Among the benefits resulting from the operation was, he remarked, to be noted the frequent improvement in the condition of the bowels; in its faulty position the uterus often increased the tendency to constipation or led to irritation and straining; the pressure once removed it was nearly always found that the action of the bowels showed marked improvement; some patients stated that for years they had not experienced a satisfactory action of the bowels until after the operation.

It is satisfactory to record that the patient left the hospital three weeks after the operation quite well and with the uterus in good position.

WEDNESDAY, AUGUST 30, 1899.

DEATH CERTIFICATION.

THE value of a well devised system of certification of death to the community is none the less essential because, it is to a great extent, self-evident. One of its primary functions undoubtedly tends towards the protection of the life of the individual. Another result of vital importance to those engaged in the scientific study of public health is the furnishing of detailed statistics of mortality whereby the incidence of disease and the progress of preventive measures may be ascertained with some considerable approach to accuracy. In the columns of a medical journal however, it is hardly necessary to enter into the advantages accruing from a well considered system of death certification, for the subject in its practical aspects is constantly before every medical man during the whole of his active professional career. It will be noted that we have spoken of the good to be derived from a sound system of registration of deaths, and have carefully abstained from alluding to specific laws as at present imperfectly administered. To make a short statement, the attitude of the medical profession towards the system as it stands is one of strong con-

demnation. The death certificate is unsatisfactory as an evidence of decease, because there is no obligation on the part of the medical practitioner to view the body, and the identification of the deceased is of a superficial character, or is absolutely wanting. One of the chief causes of laxity is the readiness on the part of the local registrars to accept certificates from midwives, chemists, and other persons who are not legally qualified to practice medicine. By issuing stringent directions to refuse all such testimony the Registrar-General would by a stroke of the pen do much towards perfecting the present system. At the same time, however, something would have to be done in order to make inquiry by the coroner, and a post-mortem examination obligatory in all cases. Official discretion is a valuable thing in its way, but in the matter of death registration there is reason to think it has gone a long way towards pithing the marrow of the whole proceeding. In cases of illegitimate children the danger of accepting a midwife's certificate is increased a hundredfold, and abundant opportunity is thereby afforded to the child murderer. A simple way out of the difficulty would be to insist that no corpse should be buried without the certificate of a duly qualified medical practitioner. If he has not attended the deceased during life then he shall grant his certificate on the strength of a post-mortem examination, and in the latter case his evidence shall always be given before a coroner's court. The only further essential needed is that the death certificate should be paid for by the State. There is no other profession that could be induced to grant responsible documents without recompense in the shape of a suitable honorarium. There is some reason to hope that within the next few years some amount of attention will be bestowed upon medical matters by the Legislature. If so, the question of registration is one of the most urgent, and every medical man in the United Kingdom will do well to make himself acquainted with the bearings of this issue, which, although comparatively simple, yet has a wide influence on his professional career.

HOSPITALS AND THE OUT-PATIENT INQUIRY SYSTEM.

THE method of appointing inquiry officers in the out-patient departments of hospitals is at present on trial in London, and some remarks upon the subject by Mr. C. S. Loch, Secretary to the Charity Organisation Society, published in the *Times*, seem to call for consideration. It was in 1897 that the Hospital Sunday Fund intimated to the various hospital authorities that they were desirous of seeing the inquiry system adopted, and in fulfilment of this expression of opinion many hospitals proceeded to appoint inquiry officers in the out-patient department with a view to the detection and checking of abuse. Mr. Loch in his communication refers to the last annual returns in this regard, which the officers have furnished. These are not.

without interest. Perhaps one of their most noticeable features is the diversity which they show. For example, at one hospital with an annual roll of about 109,000 out-patients, the inquiry officer was only able to discover, during last year, fifty-four out of this number who were unsuitable for charitable relief. On the other hand, at another hospital which deals with nearly 37,000 out- and casualty-patients in the year, out of 12,562, 1,069 were inquired into and 335 (or 31 per cent.) were rejected. Again at a third hospital the rejections reached 28 per cent. We doubt, however, if Mr. Loch is quite fair in these percentages, assuming that they are his. It seems to us that the percentage of abuse should not be based upon the cases of rejection, among those especially inquired into, but upon the whole number of patients who present themselves for treatment. The aim and intention of the inquiry system is to ascertain the extent of the abuse, and obviously the only way of arriving at a definite conclusion upon the matter is to furnish the figures showing how many patients attended at a hospital, and how many, out of that number, were deemed to be unsuitable for charitable relief. According, however, to Mr. Loch's estimate, only the percentages are given, which show the rejections among those into whose circumstances special inquiry was made, and it is clear that these figures are destined to give a false impression of the abuse which existed. But in discussing these figures of the inquiry officers, Mr. Loch complains that they show the inadequacy with which the system is being carried on, apparently basing this opinion upon the fact that the returns indicate that it is not usual to inquire into the circumstances of every applicant who comes for relief. In this connection he maintains that if in all the cases attending at the hospitals dealt with in the returns investigation had been made, the rejections would have been very considerable. Surely however, it is not the intention to make this inquiry system develop into a "detective method of procedure" by which the deserving poor will be called upon to render a full account of their domestic affairs whenever they present themselves at a hospital. We cannot believe that it is at all necessary to carry the system to any such extent, nor can we believe that Mr. Loch is correct in his assumption that if inquiry were made into every applicant's affairs that a large increase in the number of rejections would be the result. It seems to be quite possible that a competent and experienced inquiry officer should be able to tell at a glance whether an applicant at a hospital was or was not seeking to abuse the charity; in short, in all cases in which applicants are clearly poor persons no inquiries should be made into their circumstances. It is not to be supposed that the poor are insensitive to the demand made upon them to divulge their domestic affairs; they would not be human if they did not feel resentment under the circumstances. Clearly, therefore, they are thoroughly entitled to consideration in the matter, and we submit that to injure their feelings by asking unnecessary questions

under the inquiry system, is equivalent to carrying that method to an unwarrantable and mischievous extent. There is no doubt that abuse of medical charities exists, but a greater abuse of another kind would soon come into existence were every hospital to become the arena of detective procedures compelling the poor to divulge in all cases when applying for relief the privacy of their homes. Again, this system, conducted upon these lines, would further, we believe, have another deleterious influence. It would undeniably tend to destroy the self-respect in the deserving poor, for whom, after all, hospitals are maintained. Altogether, we think that much harm may be caused both to hospitals and the community unless the newly introduced inquiry system be conducted reasonably, with circumspection, and upon lines of expediency.

THE ALLEGED INCREASE OF LUNACY. IRELAND.—III.

To resume from last week. At page 31 of the Inspectors' 46th Report, these gentlemen state with considerable self-gratulation: "The accommodation, when first constructed, was little better than in prisons—they are now comfortable places of abode with easy provision for the proper care and treatment of the inmates, and, so far as is reasonable for their comfort and recreation, to the influence of which attractions may be ascribed in no small degree the increased population of these Institutions." The italics are ours, as emphasising an admission of permanent significance, and is corroborated by their statistics—the number of lunatics set down as resident during the gloomy epoch of decadence in the District Asylums being 13,000 (round numbers), and 19,590 in 1897—that is as much as saying we suppose that the living therein is so pleasant and attractive—the ideal of the *dolce far niente*, that not only will the inmates accumulate but the outer ones will be attracted. Now as we inquired before, how are the 5,000 at large known to be lunatics—and is it a certain fact that the 20,000 are all insane, fairly chargeable to their respective Districts, especially to the Metropolitan, upon which we have shown such huge sums of money have, and are being expended. Where is the Treasury, or other actuary to ascertain this? A report was printed some years ago pointing out means by classification of asylums and otherwise for putting things on a right basis. Why, at least, was not so much of that report enforced? The assumption that lunacy is not really on the increase in Ireland is further favoured by the fact that its registered increase among the better classes remains practically stationary, the stock causes alleged in producing it being the same in variation as in those in the Public Asylums (see pages 52 and 84 of the last published Report—the 47th). Further, while the "causes" are common to both classes, the modes of admission and antecedent circumstances are quite different. The average now standing in the Private Asylums would appear to be 677, based on the returns of the last three up-to-

date years, being registered respectively as 663, 676, and 691, as derived from the Blue-Books—so far back as 1880 the number was 622, and the average, based on the series of years, subsequently to 1895, is 632, so that for twenty years the number registered has not got out of the six-hundreds—we think a deduction, unless shown to be inaccurate, showing most conclusively that the development of the public asylums is responsible for the registered increase; in other words, that they are luxurious refuges for the poor and destitute, fortunate to escape there from their squalid surroundings and the opposite being the rule in the better classes. We have already expressed our doubts as to the accuracy of the deductions drawn from official statistics upon abstract subjects, respecting which all sorts of ingenious and complicated groupings may be devised, especially as regards insanity by faddists, having a turn that way. It seems to us almost as difficult to reduce its kaleidoscopic manifestations to figures, as those of genius, poetry, or any other mental determination. In justice to the compilers of some of the recent Irish Lunacy Blue-books, it should be admitted that they present the various registrable aspects of insane statistics through the old grooves in the fullest and clearest manner, withholding nothing calculated to enable students of the subject to see how it actually stands and form their own opinions—certainly affording a marked contrast to the jumbled and incoherent statistics presented through the medium of the voluminous Blue-books of some previous decades, which were utterly destitute of point or method, and looked as if they were distilled from the seething brain of a person mad with figures. But these are occasionally spontaneous admissions, apparently the outcome of an *enfant terrible*. We only regret that, as pointed out in a letter to the *Nation* of 3rd last April, the practical subject of expenditure is not fully given under the headings of salaries, allowances, and pensions, as showing all the consequences in addition to those we have touched on, of the tremendous increase in registered insanity. There would then be a nearer approach to a complete case being stated. It must certainly be also admitted that so far as we have searched we cannot find that the inspectors commit themselves to a positive opinion, or indeed any opinion at all, as to whether insanity is really increasing or not; they give full data, according to their light, and apparently leave others to find conclusions. There are in Ireland 20,000 registered and 5,000 unregistered lunatics, or thereabouts. We therefore presume that the latter are as dangerous to society as the former, and have as much right to asylum treatment, that there are in the asylums many who have no right to be in such costly structures, and many outside who have. What therefore should be done? It is a question for intelligent physiological experts, men of the world with a profound knowledge of human nature, and single-mindedness, not for Commissions, Treasury economists, with their

complacent second-hand utterances in the best Queen's-printers' type, or self-seeking place hunters. All the alleged lunatics both inside and outside should be subjected to some filtering process, and as stated in the *Nation* letter, we think suggestively, such tests should be applied by zealous and competent authority, as would indicate individually the exact stage below the "sound mind in the sound body" where such insanity begins and responsibility ends as warrants the restraint and treatment of its victims in expensively equipped institutions. If this were practicable it would bring the whole matter to such a test as would produce definite results, and we think the attempt should have been made before the shekels were expended. Within the last twenty years a Commission took the view that lunacy *directly* under the Local Government Board, would have met every exigency of the case. There were then special *personal* reasons. It had no result. Some years later an ardent Scotch specialist changed all this, and inspired different views, equally futile as regards a settlement of the *question*. Now we have the new Local Government Act essaying to deal with it as best it can on an entirely financial basis, with meagre data, instead of having it under its own Board of Administration, so that we suppose insanity will go on increasing, until the exigency of the money question becomes acute. We have already referred to the appearance of the English Report; we await its Irish reflection.

Notes on Current Topics.

Golf and Neurology.

It has been said that every other man in America is now so addicted to Scotch ways and habits that he wears heather-tweeds, plays golf, drinks "Scotch," and says "Hoot's mon." Of such must be Dr. Irving C. Rosse, Washington, who contributed to the American Neurological Association a paper on golf from a Neurological view-point. Medical men have their hobbies in sports and pastimes, and these are sometimes regarded with a professional eye and with a bias in their favour which is largely due to the man's own aptitude and predilections. We are told that here we have a royal road to physical exhilaration in a game that can be played all the year round, independently of atmospheric vicissitudes, during all the seven ages of man, by delicate young girls as well as by strong athletes, and even by decrepit old men, whose declining powers do not admit of severe exertion. We must, however, dissent from the statement that there is absolutely no danger attached to the game, and that consequently no accidents ensue. Dr. Rosse is evidently new to the game and knows little of its history, even its latest history, or he would know that fatal accidents have occurred, at least in Scotland, from golf ball strokes. There is a great deal to be said in favour of golf for those suffering from heart lesions, arterial calcification or certain hysterical conditions, and undoubtedly as a medical adjunct it is not to be

despised. Dr. Rosse, while enjoining moderation, alleges that benefit has been derived in some cases of cough, nervous asthma, and in affections of the bladder and prostate; but it is pre-eminently in functional nervous disease that our great Anglo-Saxon game is to be recommended both as a prophylactic and curative. As to its being a certain remedy for insomnia, there may be some doubt as we have met, within the last few days on the golf course, a golfer, who despite his golf exercise, suffered from insomnia. A great deal might be said in favour of golf as a mental and nervous tonic, but not to the exclusion of other sports which have many of the same advantages. Undoubtedly it is a good thing for the physician to know from his own actual experience the physical requirements of different games, and their physiological uses. The use of golf as a remedy in the treatment of nervous ailments of a functional character, whether they affect the mental or visceral spheres, is worthy of all consideration.

The Workhouse Doctor as Undertaker's Help.

It will be recollected that the guardians of North Uist, in Scotland, had got themselves into serious trouble by their persecution of their medical officer, Dr. Lamont, whose case was brought before Parliament and elicited most sympathetic assurances from the Lord Advocate. The guardians have now retorted on him by charging him with savage conduct in confining the body of a pauper. At present we are not concerned with the truth or falsity of these charges, but we should like to know whether in North Uist or elsewhere it is any part of the duty of a medical officer to act as undertaker's help in confining deceased paupers. It seems incredible that any self-respecting medical officer would allow such a filthy function to be imposed upon him.

The Block Against Domestic Legislation.

WE have frequently commented upon the difficulty—the almost impossibility—of obtaining reforms of the laws or system which govern domestic or class interests unless the objects aimed at seem to be large enough for the Government to take them up as part of their political programme. Legislation on the initiative of private members is practically dead, and as all the bills which affect the medical profession are of this class, progress or reform in our laws is practically blocked. This fact is illustrated by a recently published return of the number of bills promoted in last Parliamentary session. Out of the total of 117 days during which the House sat, the Government seized 98, leaving only 19 for consideration of all private bills. Needless to say, not more than one in a dozen of such bills ever got beyond a first reading, and not more than one in fifty got through its stages. Really, as the phrase goes, something should be done to afford a chance for legislative reform of defective laws on domestic subjects. The Government, we submit, has not discharged the whole of its duty by passing one or two great contentious bills in the Session. If the time

expended in debating the London Government Bill, for which the nation cared little or nothing, had been given to domestic legislation, a host of such bills which never had a chance could have been disposed of. As the matter stands, the “hope deferred” has made the hearts of private members sick, and they are giving up even the demonstration of principle implied by the introduction of a bill.

Enteric Fever in the Indian Army.

THE subject of typhoid fever in the Indian Army like the poor, is always with us. Early in the present month a brief and unsatisfactory statement upon the point was made by Lord George Hamilton in the House of Commons. The main fact of the position is that of late years the disease has increased rather than diminished. An experience of that kind is directly the reverse of what usually happens in any community of average sanitary enlightenment. What preventive administration could explain away the awkward fact that in several Indian stations enteric fever is now admitted to be endemic? With practically no limit to the amount of reasonable expenditure within their command the long continuance of enteric fever in a particular station brands the responsible local administration as hopelessly incompetent. The truth appears to be that the Indian Medical Service is lamentably behind the times. The spirit of militarism regards advanced scientific methods with suspicion, and woe to any junior officer who attempts to advocate the latest and most approved plans of investigation and prevention. At the recent Portsmouth meeting of the British Medical Association an Indian Medical Officer was able to boast of the fact that three distinguished scientific civilians had been given official posts. The concession is doubtless a forecast of coming events, but the candour of the speaker would have been more conspicuous had he not omitted to add that the appointments had been made only within the past few months.

The Superstition of Spitting.

THE habit of promiscuous expectoration is an uncleanly, disgusting one, but how curious it is that it should be envired with so much superstition. In days of antiquity spitting was resorted to in order to ward off dangers, and up to the present time luck is wooed and misfortune avoided by the process of spitting. Newborn children are treated to a lavish expectoration by midwives in certain parts of the country; fishermen spit upon their hooks after baiting them, and it is considered to be absolutely essential before washing in the same basin in which a friend has washed, to spit into it, for otherwise a quarrel would be sure to follow. But it is on the Continent that the superstition of spitting seems to reach its worst degree. In Oldenburg, for example, the loathsome custom prevails of always spitting three times into the kneading trough. Again, babies in Hungary are especially singled out as objects of the superstition; the custom there is to spit into the babies' faces in order to bring them good luck. Imagination almost fails to picture the filthiness

and danger of such a disgusting act as this. In Silesia and Bohemia, persons generally spit three times when they meet an old woman, but it is quite difficult to conceive why the presence of an aged female should thus call for such a profligate evacuation of the salivary secretion under these circumstances. Again, in Sweden, a great deal of superstitious spitting seems to take place. Persons, for example, spit into their beds before retiring; playing cards are spat upon when the luck is bad, and every new suit of clothes is made the object of a gross expectoration, but for what reason it is quite impossible to imagine. Superstitions are said to die hard; and it would seem, from the above facts, that the one under discussion has been endowed with a phenomenal vitality. Despite its absurdity, filthiness, and unhygienic character, it has still survived; whereas, on sanitary grounds, it should, without further loss of time, be "coffined" and confined beyond all reach of resuscitation.

The Operative Treatment of High Myopia.

ONE of the special features of the recent International Congress at Utrecht was the grave warning given by Dr. Wolf of Melbourne (formerly of Glasgow) and Professor Silix of Berlin against the indiscriminate extraction of transparent lenses for the cure of high myopia. Passing by the consideration that the operation destroys the accommodation, and *pro tanto*, injures near vision, these very capable critics pointed out that of itself the operation of removal of the normal lens has always been recognised as a specially difficult and dangerous one. The chief ground of objection is the probability of detachment of the retina as the result of the manipulation in an eye which for years had been subjected to chronic sclero-choroiditis. Dr. Wolf considers this danger so real that he warns the profession that a wholesale performance of the procedure would mean a wholesale sacrifice of eyes, and he urges that it should only be done in exceptional cases. Professor Silix confirmed this warning by the statement that in an experience of nine months he had observed twenty-three cases of retinal detachment after extraction of the normal lens, and only three cases without such operation. On pathological grounds the contention of Dr. Wolf and Professor Silix seems to be justified.

Cockle-Typhoid.

A SIMULTANEOUS outbreak of enteric fever in different quarters of Exeter has recently been investigated by the Medical Officer of Health. As a result of his inquiries, it was ascertained that all the persons included in one group of notifications had visited Exmouth and there had eaten raw cockles gathered from the mud-flats close to a sewage outlet. In the absence of other apparent source of infection, the local authorities seem convinced that the origin of the epidemic may be traced to the infected shellfish. It has been suggested to the Exmouth Council that the sale of cockles taken from that particular part of the foreshore should be in

future prohibited. Fortunately for the public, cockles are rarely eaten in an uncooked state, or infection from that source would be doubtless a far more common event. In the case of oysters, there are solid gastronomic reasons why they should be eaten raw. Who that has known the delicate English "native" fresh from his watery lair would thereafter hear of that toothsome tit-bit being stewed or roasted? Such devices of the kitchen may be needed for second-rate foreign oysters, but not for the aristocratic British mollusc. But henceforth let every sane inhabitant of the United Kingdom who wants to eat cockles see that they are boiled.

Sunbonnets for Horses.

IT is now two years since the above subject was introduced into the columns of THE MEDICAL PRESS AND CIRCULAR. Our remarks thereon commanded the widest popularity, and were even immortalised in the pages of *Punch*. The suggestion was at the time received with some amount of sarcasm and incredulity, but the summer covering for the horse's head is now an established fact. At various English seaside places this year the equine bonnet has been in evidence, and has ceased to attract any more special notice than a motor cycle or a lady rigged out in the most rational of "bloomers." It was at first hoped that the horses' bonnet, if introduced, would materially assist in the revival of the straw hat trade at Luton, but we note that not a few of the new hats are made of a thick glazed calico material. The effort to protect horses against the effects of the sun may be regarded as humane rather than scientific. It is doubtful if heat stroke, in the ordinary sense of the term, ever attacks the horse. Sudden syncope in hot weather may usually be ascribed to over-work and want of water. A horse naturally wants more to drink in the hot weather than in cold. How many horses, private and otherwise, are provided with an extra supply in summer?

Metropolitan Workhouse Administration.

FROM time to time incidents occur in the workhouses of the metropolis that prove the urgent want of reform. If we mistake not, Stepney has earned an unenviable reputation in that respect, a suspicion that tempts one to urge the necessity of a searching inquiry into two recent "scandals." In the first instance a father called to see his child, a patient in the Stepney Union Infirmary at Bow, and was told that the boy was asleep, whereas he had been dead for a period of time it is impossible now to determine. From evidence tendered to the Coroner it appeared that two night nurses were expected to look after six wards containing one hundred patients. This understaffing is nothing less than a scandal and a disgrace to London. The Coroner remarked that at one time there was only one nurse to 800 patients in the workhouse, but there were now six, the increase being mainly due to representations by juries. Where is the Local Government Board, and what have the

official inspectors to say to the continuance of that state of affairs? The second occurrence was the death of a young man who was placed in a straight waistcoat by an attendant, and died apparently without having been seen by a doctor. Death was due to pneumonia. If the facts are as reported, we have no hesitation in saying the affair is a disgrace to civilisation, and reflects no little discredit upon the controlling administration of the Local Government Board, with whom the responsibility ultimately rests. Will the Board kindly look up the records of Stepney Workhouse, with special reference to inquests held upon inmates during the past dozen years in and out of the padded room?

The Law Regarding Death Certificates.

THE law is very clear upon the point that a medical man is bound to give a death certificate in the case of patients whom he has attended during their last illness. Moreover, on failing or refusing to do so he is, on conviction, liable to a penalty. A Birmingham practitioner was, therefore, clearly in the wrong by refusing a certificate of death to a parent whose child had died under his care. Nevertheless the facts of the case are not without interest, and, as disclosed at an inquest, are as follows:—A five days' old infant of a labourer died, and the medical man who had attended its mother in her confinement refused a certificate of death on the grounds that the father had broken his promise to pay the midwifery fee of fifteen shillings. Ultimately the coroner for the district was communicated with, and an inquest was directed to be held. It then transpired that the practitioner had, without giving notice to any one, forwarded the required certificate of death to the local registrar, a course which would have been sufficient to have removed all the difficulties in the case if only those concerned had been informed thereof. However, the coroner pointed out that three offences had been committed by the practitioner under the Act. First, he refused a certificate; second, he wrongfully sent a certificate direct to the Registrar; third, he failed to report to the father what he had done. In defence of his action the medical man desired it to be known that he had done a great deal of gratuitous work in his neighbourhood among the poor, and that he refused the certificate because the husband of his patient had not kept his promise in regard to the payment of the reduced fee of fifteen shillings. He regarded, therefore, the action that he took in the matter, although illegal, as a punishment to the man for his failure to discharge the debt. Reference was further made to the fact that the class to which the husband belonged, not infrequently made use of "medical certificates"—surely not death certificates—for begging purposes, and it was for the purpose of avoiding such a contingency that he sent the certificate of death direct to the Registrar. While, however, we can quite sympathise with the medical man at the shabby treatment which he received from the husband of his patient, nevertheless, it is impossible to

defend the steps which he took in the matter. Moreover, it was scarcely a dignified method of showing his resentment by doing that which was perfectly illegal. However, it is satisfactory to note that the jury took the very sensible view that the case did not call for any expression of censure on their part.

The Malarial Mosquito.

THE Liverpool School of Tropical Diseases has scored a distinct triumph through Major Ross, I.M.S., one of its staff. Major Ross telegraphed from Sierra Leone to the chairman of the school last week, "Malarial mosquito found, ask Government to send at once men." The expedition to the Gold Coast, organised by the Liverpool School of Tropical Diseases, has thus proved already successful in attaining its object, namely that of discovering the malarial mosquito. But further investigation, of course, is needed, and more assistance is required for carrying on the work, hence the request in the telegram for aid from the Government. There is every reason for believing that in this discovery a notable advance has been made in the etiology of malarial disease. It is too early yet, of course, to speculate upon its value and the beneficial effects in which it is likely to result; but we trust that the Government will realise the importance of the discovery, and will not fail to comply with the request for further assistance to prosecute the researches which have still to be made. As a commencement in this direction the Liverpool School have selected Dr. Fielding Ould to go out to Sierra Leone. Dr. Ould will start from Liverpool on the 2nd prox.

Prescribing Chemists.

SOME correspondence lately in the *British and Colonial Druggist* seems to indicate that prescribing chemists do not wish to usurp the duties of medical men, and that they would only be too glad to cease prescribing over the counter if medical men would cease dispensing their own prescriptions. "We only prescribe," says a correspondent, "in the interests of self-preservation; the doctors usurp our functions, so we have to prescribe to get a living." This statement throws quite a new light upon the matter, in claiming that chemists in order to carry on their trade and gain a livelihood have to resort to a procedure in regard to which they cannot admit that they possess any legal qualification. Moreover, the argument advanced is not a sound one. Medical men who choose to dispense their own prescriptions are acting strictly within their legal rights; on the other hand, chemists who prescribe are doing that for which, under certain contingencies, the law will hold them responsible. Furthermore, we question the correctness of the view that chemists suffer so much loss of trade at the hands of medical men. If, instead of prescribing for his customers' ailments, a chemist referred such persons to a neighbouring medical man, it is certain that the latter would refer them back again with prescriptions to be dispensed by the tradesman. Such reci-

procuity would only be natural. Again, it is well known that medical men have often owed their introduction to good patients through the agency of chemists, and under these circumstances both tradesman and professional man mutually support the interests which belong to the calling of each. We think that it is altogether a mistake for chemists to suppose that they serve their own interests best by trying to compete with the medical man. What they should aim at is cultivating the goodwill of practitioners, with a view to securing their custom; the statement is doubtless quite true that many a medical man would send his prescriptions to be dispensed by a chemist if the assurance were forthcoming that only the dispensing would be done. Possibly chemists may "self preserve" themselves for the time being by the practice of counter prescribing, but they are never likely, so long as they continue doing so, to add much to their business through the help and recommendation of members of the medical profession.

The Boom in Sanatoria for Consumption.

ONE of the most noticeable features in the consumptive crusade is the present development of the idea of the open-air method of treatment. In all parts of the country we read of schemes being launched for the erection of sanatoria. If the Prince of Wales has done anything in this tuberculosis movement, he has certainly been the means of providing a new outlet for capital among those who possess it. To be financially connected with a sanatorium has proved in several instances, so far, to be an excellent thing. Now is the time to embark upon such enterprises, if the desire is to make money out of them. The supply by no means yet equals the demand, nor is this likely to be the case for some time to come, judging from the large number of hapless victims of phthisis in this country, who will probably be only too eager to profit by the new treatment, as soon as facilities exist for the purpose.

Methodical Suicide by Inhalation of Illuminating Gas.

A CASE of poisoning under unique circumstances was investigated at a London inquest last week. A man in a respectable position in life took a lodging for one night, and shut himself up in his bedroom. He was found in the morning—eight or nine hours after death—seated in a chair with one end of a rubber tube in his mouth, the other end being fixed to the burner of the gasalier, which was turned full on.

Dangerous Adulteration.

PERHAPS the most dangerous and evil form of adulteration practised by dishonest tradesmen is that of imparting an artificial green colour to preserved vegetables by the use of sulphate of copper. The *British Food Journal* has just drawn renewed attention to the extent to which this practice prevails. Our contemporary asserts that enormous quantities of tinned and bottled peas, beans, and spinach, "greened" by this artificial method are now in the market and command a ready sale. The only way

that the public can protect themselves against purchasing these poisoned products is to exact a guarantee that the products which they purchase are free from this abominable adulteration. The risk, however, is so great of being poisoned by this means that it would be much the best to avoid buying tinned or bottled green vegetables altogether.

The High Death Rate.

It was only to have been expected that the long continued drought would have an evil influence upon the public health, and as a matter of fact the death-rate throughout the United Kingdom last week was higher than it has been for the past two years. The deaths registered in London alone numbered 2,208, being an excess of 473, and equal to an annual rate of 25.3 per 1,000. The chief, almost half, the loss of life, occurred among the youngest infants, among whom the cause of death was mainly acute diarrhoea. Of the other causes of death, it is satisfactory to note that there was a decline in that of measles, while the other 29 zymotic diseases were below the average, and the mortality from diseases of the respiratory organs was the lowest recorded during the past twelve months.

The Vaccination Contest in Leicestershire.

THE Lutterworth Guardians, having been called upon to appoint a vaccination officer, did so, but under the condition that he should institute no prosecution without their special sealed authority, which every one knew that they were determined never to give. The English Local Government Board has intimated to the guardians that they are advised by the law officers of the Crown that any such limitation or condition is totally illegal, and that any appointment made thereunder is void, and the Board requires that a valid appointment shall be forthwith made. If the guardians still refuse—as they probably will—the Local Government Board can proceed to make the appointment themselves.

Scotland.

[FROM OUR OWN CORRESPONDENT.]

THE LATE DR. JOHN DUNCAN, M.A., M.D., LL.D., F.R.C.S.Ed.—Members of the medical profession in Edinburgh, without doubt, medical men throughout all Scotland, were shocked to hear of the sudden and unexpected death of John Duncan. Those familiar only with his personal appearance, and aware of his devotion to and skill in all that appertains to sport and to games of endurance, would hardly be expected to know that his strong frame had of late years been handicapped by a weakened heart. His more intimate friends knew more about the danger which threatened him, and, although surprised and taken aback by his sudden decease, had been for some time disturbed by his continued display of muscular energy and endurance, which seemed to exceed the bounds of prudence. Dr. John Duncan died from cardiac failure after, it is said, a day on the moors of Skye, where for a year or two he has rented a shooting and deer forest. For some time back he had shown signs of gouty invasion of his cardiac structures, although unaccompanied by any very noticeable deterioration of pristine muscular powers. His

grandfather, the founder of the well-known firm of chemists in Edinburgh, Duncan and Flockhart; his father, Dr. James Duncan, a prominent surgeon in Edinburgh in his day; John Duncan selected medicine for his future profession. But before becoming a medical student he attended the arts classes in the University of Edinburgh, and obtained the degree of M.A. His progress through the medical curriculum was marked by various successes. His fellow-students elected him Senior President of the Royal Medical Society as a token of their esteem; he filled various junior surgical posts in the Royal Infirmary in succession; became an Assistant Surgeon to the same, whereupon he relinquished all practice save surgery; lectured on Surgery in the Extra-Mural School of Medicine, at first to a handful, before relinquishing the post to large numbers, of students; and, in short, became one of the foremost surgeons of Edinburgh. The work for which he was best known dealt with the method of application of electrolysis, and the advantages connected therewith, in the treatment of aneurisms and nævi. To him also should be accorded the credit of an early appreciation and advocacy of Lister's antiseptic doctrines, and of successful action taken on behalf of the Extra-Mural School of Edinburgh for more extended privileges being allowed to University undergraduates in their choice of teachers. Duncan's work for the M.A. degree endowed his mind with a culture which it never altogether lost. His temperament was philosophical, cautious, inclining to action upon second thoughts rather than at once; his judgment was sound, as a rule, but was apt to err from his tendency to base it upon too many possibilities, especially upon too optimistic hopes. To the thoughtful student all that he said in class or clinique was full of instruction; to ordinary parrot trained types his words conveyed but little meaning beyond the actual naming of facts, hazy in form because their minds lacked the more general knowledge presupposed to be in their possession by the lecturer. The same might be said of him as an operator. Careful, skilful, but cautious; thorough, but hardly daring enough; when resolved upon operation he did his work well; but he was hindered often by his natural tendency to delay, to hope for the best, to trust nature to accomplish in the case what she had done in some other instance known to him. Especially in abdominal cases was this hesitancy shown.

It was a common secret that he declined more than once a seat in Parliament, as representative of a Scottish University constituency; the hurry and excitement of active politics were distasteful. But as member of the Edinburgh University Court, of the Council of the Colleges' Medical School, an active participant in the proceedings of the Royal College of Surgeons of Edinburgh (he was President of the College in 1894), as a manager of the Royal Infirmary, and member of many other public and semi-public posts, his calm and reasoned opinions were often invaluable.

In all games of endurance and skill, and in all kinds of sport, John Duncan was prominent. His strength of muscle was great; his accuracy of eye unailing; in his day the best wicket-keeper among Scottish cricketers; a prominent rifle shot; an adept at casting a line for salmon, his achievements in this way were phenomenal; a first-class shot at grouse or in deer-stalking; a noted curler (perhaps his most favourite game); and latterly a golfer of no mean merit. He had also an artistic bent, and many oil-paintings of Highland scenes, of considerable power, graced the walls of his infirmary wards and side-rooms, the products of his brush.

When medical men in Edinburgh were at a loss about anything of importance, as to what they should do, it was generally suggested, "Ask John Duncan." Now, alas, his help can no longer be sought for; his judicial mind will never again aid or advise his brethren in medicine.

THE Colonial Office officially reports that for the week ending August 28th there were fifteen fatal cases of plague in Hong Kong.

Manchester.

[FROM OUR OWN CORRESPONDENT.]

ROYAL INFIRMARY.—The battle of the sites still continues. The difficulty in arranging for the future of this, the leading medical charity of Manchester, seems insuperable. A special committee, consisting of members of the City Council and Infirmary Board, recommended a scheme, the chief features of which arranged for the payment by the Corporation of £250,000, the collection by the Corporation from the public of £50,000, and an annual payment by the city of £2,500 for twenty years, thus making a total of £350,000. For this the city was to be allowed to acquire the present site, admittedly the finest in the district, provided they reserved an area of 3,000 square yards for a receiving and out-patients department, and that not more than 7,216 square yards of the whole site be covered with buildings. This scheme of compromise when presented to the Council on Wednesday last met with but little favour. Many objections were made to removing the infirmary from its present central position. An amendment proposing to allow the consideration of the question to be adjourned indefinitely was lost by the casting vote of the Lord Mayor. Finally, it was decided that the whole subject be referred to the Special Committee for further consideration. And so the matter rests apparently as far off a satisfactory settlement as ever.

OWENS COLLEGE.—Once again the time honoured custom of opening the Session with an "Introductory Address" is to be adopted. Sir J. Crichton Browne, LL.D., M.D., F.R.S., has accepted the invitation to fulfil this pleasing task. Members of the profession have been invited to attend. The address will be given in the Physiological Theatre on Monday, October 2nd, at 4 p.m.

SOUTHERN HOSPITAL.—The south side of the city will before long be provided with an elegant and well-equipped hospital for women and children. Plans are now completed, and it is hoped that sufficient funds will shortly be obtained to permit of the erection of the hospital in the Whitworth Gardens as proposed.

SUMMER DIARRHŒA.—The heat has been very oppressive during the past week. As might be expected, diarrhœa has been very prevalent. The deaths numbered 105. Of these 89 were infants under a year, and of the 373 deaths from diarrhœa and English cholera registered during the last eight weeks, 297 were under twelve months.

WATER SUPPLY.—In spite of the enormous consumption of water during these hot summer months, Manchester has no anxiety regarding its supply. Lake Thirlmere will not run dry just yet. The daily consumption is estimated at 40,500,000 gallons. Sixty-four days' supply still remains.

Correspondence.

We do not hold ourselves responsible for the opinions of our correspondents.

THE CONTROL OF THE BRITISH MEDICAL ASSOCIATION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I referred last week to the necessity of making the meetings of our Council open to the press and the members. Further consideration of the subject induces me to lay more stress on this point than I was in a position to do at that time. When our representatives are present at our branch meetings we find them anxious to fall in with the views of their constituents; when, however, they are present at the Council meetings they apparently forget their constituents, and only vote as they are directed by their leaders. Take the question of medical defence as an instance. It can hardly be denied that several of the members of the Council were decidedly in favour of the propo-

sition that the matter should be referred to the individual members of the Association, and on the proposition of (I think) Dr. Myrtle, it was resolved that certain questions should be sent to all the members asking for their opinion on certain points. Did any member of the Council vote in favour of that proposal? Unless I am seriously mistaken there was not one member of the Council who voted in favour of it. This may be said to be ancient history, but it appears to me a typical example of the Proceedings of the Council.

Respecting the publication of the Proceedings of the Council; it is well known that at the Portsmouth meeting the Council were sharply divided as to the merits of the two candidates for the important office of President of Council. I venture to say that the members should be made acquainted with the details of the votes given. Personally, I am of opinion that the Council have chosen a very excellent man to preside over their deliberations; at the same time I cannot help feeling that a gentleman who has held the office of President of the Association should not have sought after any further distinction.

With respect to the conduct of the business of the Association at the annual meetings, it may be truly said that the Association has, through its permanent officials, got into a groove, and not all the King's horses will ever be able to get them out of that groove. It is for the members to try and see whether their power is greater than that of the officials. Year in, year out the old and bad system remains. The Association tries to do more work in four days than it is possible to accomplish in twice that time.

If we are bound to meet at the end of July or the beginning of August, for heaven's sake let us try and see whether the actual routine business of the Association cannot be got through with less worry to the members and less irritation to the Council.

We are, no doubt, a God-fearing and a religious body, but is there any good reason whatever why we should devote a whole morning to religious exercises? Let us take a common sense view of matters, and get through our necessary routine business on Tuesday, and not spread it over three days as we do, and have continued to do for the past twenty years.

The absurdity of expecting members to remain and transact business after they have listened to an oration on medicine or surgery of an hour's length is too much to expect at any time, but more especially when the thermometer usually stands at 80 degs. in the shade!

The East Anglian men are well able to look after themselves, and I therefore do hope and expect that they will not blindly follow the precedents of other meetings, but will make such arrangements as will conduce not only to the better transaction of business but will add to the comfort of all those who wish to see the British Medical Association become a greater power in the land than it has ever been before.

I am, Sir, yours truly,
A PROVINCIAL MEMBER.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Owing to my absence from home, your comments upon my letter of apology read at the general meeting on Wednesday, August 2nd, have only reached me to-day. That letter was written with reference to the discussion upon the action of the Editor of the *British Medical Journal* in excluding certain matters from the journal, which I expected would come up on Thursday, after I had left Portsmouth. I can only express regret that I was not present on Wednesday to defend the action of the Council.

I am, Sir, yours truly,
ROBERT SAUNDY.

Grand Hotel de l'Etablissement, Contrexéville
(Vosges), August 20th, 1899.

TALLERMAN v. DOWSING RADIANT HEAT CO.,
LIMITED.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Referring to the report of the above case, which appeared in your issue of the 2nd inst., and to the judg-

ment subsequently delivered, will you allow me to state that the offer of the defendants was not accepted, and the matter will again go before the Courts on appeal?

I am, Sir, yours truly,
C. E. LEESE, Secretary.

50 Welbeck Street, W., August 22nd, 1899.

THE ETIOLOGY OF RICKETS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I received from the late Sir Andrew Clark the following letter when I sent him a copy of a short treatise on the Precedent Cause of Rickets, in which I gave the results of many years' observation at the hospital in Great Ormond Street, where about 3,000 cases of rickets had passed under my care:—

"Cavendish Square, W.,
"January 23rd, 1890.

"Dear Dr. Robert Lee,—I have received the copy which you have been kind enough to send me of your very able, interesting, and suggestive essay on the Precedent Cause of Rickets. It reminds me of the best manner of Halford and of Holland, and I am much obliged to you for your consideration.—Believe me, yours faithfully,
"ANDREW CLARK."

When I read in this week's number of THE MEDICAL PRESS AND CIRCULAR Dr. Elgood's remarks on a case bearing on the Etiology of Rickets, I felt some surprise that so little progress seems to have been made since the days of Glisson in the general knowledge of the cause of rickets.

I am quite certain that any of us with the evident good sense of Dr. Elgood, and with the same experience that was afforded me, will arrive at the same conclusion as I have. Those conclusions were stated some years ago in THE MEDICAL PRESS AND CIRCULAR, as well as in my lectures at Great Ormond Street, and during the past ten years I am glad to find subsequent observation has confirmed in my own mind the opinions I then formed.

I am, Sir, yours truly,
ROBERT LEE.
89 Gunterstone Road, West Kensington, W.,
August 23rd, 1899.

HOSPITAL REFORM.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Will you kindly allow me to inform your readers that the Hospital Reform Association are making arrangements to hold a Conference in London during the second week in October?

The subjects which will be set down for discussion are—

1. The Inquiry System.
2. Payments by Patients.
3. Provident Dispensaries.

As it is most desirable that the conference should be in possession of the facts relating to hospital administration in the United Kingdom I shall feel grateful if gentlemen who are interested in the subject will communicate with me at their earliest convenience. I may add that papers from laymen will be quite as acceptable as those from medical men.

I am, Sir, yours truly,
J. GARRETT HORDER, Hon. Sec.
Cardiff, August 19th, 1899.

TWO DANGERS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The profession at this moment is beset with two great perils to which no attention is, I am sorry to say, being directed. The first and graver of these is the flood of medical preparations with which the profession is daily deluged. I say, that if a stop be not put to this, the treatment of disease will be taken out of our hands altogether. The public come to know what is ordered for them, and then proceed to order it for themselves. This is so apparent, that the fatuity which can go on sustaining this system is

something incredible. Worse than all, only the merest fraction of these much-vaunted preparations are of any value, and thus the profession are simply lending themselves to downright quackery on the mere strength of the maker's rhetoric. It seems to me to be indispensable that a small body of experts should be appointed and paid by the medical authorities and organisations combinedly, and that to them should be entrusted the task of investigating or superintending the investigation of every new preparation brought out, and that no physician should be permitted to prescribe anything until its precise value should be first certificated by this new board. It is mere nonsense to allege that busy practitioners can investigate for themselves, and that their certificates consequently can be of the slightest value. Such investigations can only be carried out in hospital wards by practitioners whose entire time is at their disposal, who have the patients constantly under their eyes, and who are adequately assisted by intelligent and industrious pupils. Is it not time that our beautiful governing bodies and the heads of our medical societies and associations should address themselves to the remedy for a state of things which is injurious alike to the public and to the profession. The other peril, which is the nursing peril, I shall reserve for a future letter.

I am, Sir, yours truly,

THOMAS LAFFAN.

Cashel, Ireland, August 2nd, 1899.

SIR CHARLES LENNOX PEEL, K.C.B.

THE death of Sir Charles, who, for very many years filled the influential and responsible position of Clerk to H.M. Privy Council, may be regarded as an event of special interest to our profession, inasmuch as no man had so prolonged and intimate experience of the making of the medical law of the last forty years. He was the confidential adviser of all the Ministers who attempted such legislation, including the Marquis of Ripon, the Duke of Richmond, and Lord Carlingford, and was the intermediary through whom were passed to these Ministers the representations of the educating and qualifying bodies, and of all classes of the public interested in medical affairs, and many of the details of the successive medical Acts were suggested by him. The experience of all who came in contact with him in this connection was that he was a most excellent chief officer of the Council, clear-headed, discreet, businesslike, practical, and industrious. His official manner was urbane, and that of a perfect gentleman with no leaven of the dog-in-office style so commonly assumed by officials in his position. It will be well if a successor as amenable to suggestion and so considerate for the opinions of others can be found to assume the official control of the Privy Council Department.

Literature.

THE ALIMENTATION OF INFANTS. (a)

THIS is one of the most carefully thought-out and practical treatises on the alimentation of infants that we have seen for a long time. The high infantile mortality which obtains in France, grafted on to a diminishing birthrate, has excited the grave interest of philanthropists and medical practitioners, and this volume represents a serious attempt to grapple with a very urgent question. In France, as elsewhere, digestive troubles are the principal cause of the enormous mortality of the first year of life, accounting for something like 96 per cent.

(a) "Traité de l'Allaitement et de l'Alimentation des Enfants du Premier Age." Par Dr. A. B. Marfan. Paris: Steinheil, 1899.

of the total deaths. As might be expected, this mortality affects more particularly infants not brought up at the breast, hence the importance of educating the public—and may we say the profession—in the risks inseparable from artificial alimentation, and the means of obviating them.

This work is divided into two parts—one, theoretical, which deals with the chemistry of milk, and the functions of digestion and nutrition in young infants; and, secondly, a practical part in which the author discusses the rules of normal alimentation. The latter part will probably be found of the greater importance by his readers, inasmuch as the author's own extensive experience enables him to supplement the observations of others by his own.

Special interest attaches to the chapter on the means of securing milk for infants' food free from disease-producing contaminations. He points out that boiling, however carried out, cannot render hygienic a milk that has already undergone partial decomposition, because though the organisms themselves have thereby been destroyed the milk still contains toxins elaborated by them which are capable of determining grave symptoms of irritation in the sensitive alimentary canal of the very young. As it is impossible for dwellers in towns to secure milk within a reasonable time after its leaving the cow (eight to ten hours in winter, two hours in the summer) domestic sterilisation is necessarily a delusion and a snare. As the author, for what appears to him to be good or sufficient reasons, deprecates the use of condensed milk, sweetened or unsweetened, he recommends the exclusive use of milk sterilised by approved methods on a large scale on the spot, that is to say, before there has been time for decomposition to have set in. He describes with great wealth of detail the various methods of wholesale sterilisation and the apparatus employed, and reviews the advantages and drawbacks of each. We have nothing but admiration for the admirable way in which the author has done his work, which we have read throughout with the greatest interest and instruction. We can cordially recommend it to those of our readers to whom the French language does not constitute a barrier.

PURDY'S URANALYSIS. (a)

THE importance which urinalysis has attained as a guide to diagnosis may be gauged by the size of this volume, and the fact that a fourth edition has been called for within the space of four years. Chemists have devoted considerable attention to the problems which urinary analysis has brought to the fore, with a certain measure of success, though the sources of fallacy are still many, and erroneous deductions still menace the incautious or too confiding observer.

The author has adopted the very convenient plan of classifying urinary abnormalities into large general groups, a plan which greatly facilitates the study of substances more or less closely allied, either chemically or pathologically. Under the two great heads of proteids and carbohydrates, we have all the analytical procedures of any value for their detection and differentiation, with an estimate of their respective convenience and trustworthiness. Abnormal substances not falling under either of these two heads—and they are many—are dealt with in a separate chapter. The chapters on "Urinary Sediments" and "Anatomical Sediments" are particularly worthy of commendation.

The second part of the work is styled "Urinary Diagnosis," and here the process is reversed. We are invited to take cognisance of the various diseased conditions of the various segments of the urinary apparatus and then, step by step, we are instructed in the urinary modifications associated therewith and dependent thereupon. The physician is thus enabled to direct his inquiry (a) into the means of identifying a given abnormal substance; (b) its pathological significance; and

(a) "Practical Urinalysis and Urinary Diagnosis." By Charles W. Purdy, M.D., LL.D., F.R.C.S.P. and S. (Kingston), Professor of Clinical Medicine at the Chicago Post-Graduate Medical School, &c. &c. Fourth edition. Detroit: The F. A. Davis Co. 1898.

(c) the effects on the composition of the urine of a given morbid condition, local or general.

The volume concludes with an instructive chapter on the examination of urine for life assurance, and a description of the reagents and apparatus for qualitative and quantitative uri-analysis.

In the present state of medical science, with its demand for precise and accurate observation, such a work is indispensable to every conscientious practitioner.

THE CHEMISTRY OF DAILY LIFE. (a)

THIS is the second edition, revised and augmented, of a work which is deservedly popular both here and in the country of its author. The work embodies the substance of a course of lectures delivered before a society at the University of Königsberg. These lectures cover a great variety of topics, as will be seen by a glance at the table of contents. The author's plan has been to show how intimately our daily lives are concerned with chemical phenomena, and he has succeeded in making chemistry, thus treated, one of the most fascinating of sciences. It is just the book for the intelligent adolescent or inquiring adult. There is not a chapter from which the reader will not glean unexpected and interesting information, whether it be the subject of incandescent gas-lights, or the manufacturing of land, questions of diet or the manufacture of explosives. No one can read without interest an account of the evolution of photography, and even the cyclist will not despise news of acetylene, its properties and peculiarities.

As the lectures are essentially for popular consumption, we should not be justified in yielding to the temptation to cavil at sundry of the author's statements. The translator has done his work pretty well, but we meet here and there with slips of grammar which surprise us, coming from an M.A. Some of his sentences, too, read rather funnily—as for instance, when speaking of sleep-producers, he says, "they produce sleep, it is true, but they also produce many unpleasant effects; and for this reason the number of those that are of practical utility have greatly diminished, although it is still certainly quite large enough."

MY INNER LIFE. (b)

THE author gives us in this volume what he calls a chapter in personal evolution and autobiography. The title is one to draw, and we naturally expect between the covers to see the author depict his evolution with somewhat more of the frankness than an autobiography, and with a physiological and psychological detail which shall make the sequences of his evolution clear and distinct, and preserve to us a picture of scientific value. As an autobiography the work is interesting, so far as it goes; but one cannot help feeling disappointed that the author is apt here and there to confound the evolution of philosophy with the evolution of himself. Even a philosopher is something more, and we should like to know something of him in his more human and material character. The data of human evolution can only be postulated as milestones so to speak, but between these milestones there is much to fill up, and many comparisons are required between man and man. When we come, however, to the subject matter of the volume, without regard to the precise aim and scope of the work as indicated by the title, we must confess to an uncommon interest in the author's descriptions and views. The style and descriptive power of the author are very good; but, still more, he is most instructive and suggestive. The work is divided into five parts, Boyhood, Early Speculations, The Lost Ideal, The Search for the Lost Ideal, and Literary Experiences. The chapter on Boyhood, though not without interest by reason of the author's style, serves chiefly as the threshold of the real purpose of the book, and brings

us to the author's early speculations, the fascinations of objective study, phrenology accepted and discarded, and, later, the evolution to a higher plane, viz., the subjective and introspective. When the author comes to the question, A Law of the Mind—what is it?—and attempts to answer the question, we feel that a gift of definition is wanting, though his illustrations are quite intelligible and certainly helpful. Particularly helpful is his comparison of mind and body, the one fighting against the circumstances that would subdue it, the other keeping the erect posture against the forces of nature that would bring it to the ground. "As the object of the action of the muscles is to restore the bodily equilibrium, so the object of the play of thought and passion is to bring the mind back to its original equanimity." The author's philosophic doubts and criticisms are well put forth, his explanation of the "lost ideal" and his history of his search after it are interesting studies in philosophy. His views on men and conduct, and manners, as seen in this country are narrowed by his own prejudices, range, study, and experience. The work altogether is worthy a prominent place in the literature of philosophy and psychology.

BURNS AND THE MEDICAL PROFESSION. (a)

WE question if any literary work outside of medicine will appeal more strongly to medical men than this. Burns's relations with our profession, if limited, were cordial and appreciative. The doctors of his day, to quote the author's words, never "boggled" over his frailties, but exhibited a wise toleration and charity, and the highest regard and enthusiasm in estimating the poet and his work. The author is himself a good type of his profession in this respect, and one reads his estimate of the reviews and criticisms of others—Currie, Carlyle, Wordsworth, Wallace, &c.—with thorough respect. The material for this work is scanty, but the author has made the most of it. He has had to introduce in the text the names and writings of not a few of the medical men who, while only knowing Burns by tradition, were able to deal with his life in no narrow unkindly spirit. Of these, the palm must be given to Dr. James Adams, a veteran Glasgow practitioner, who in the words of the author, has been "an ardent and enthusiastic Burns scholar all his life." To him we owe "Burns's Chloris: A Reminiscence," and we might add a justification. Of Burns's medical contemporaries Dr. Findlay gives several interesting glimpses, including Dr. John Mackenzie, Manchline, who introduced the poet to the philosopher Dugald Stuart, Dr. Gregory, Dr. Wood, and other medical dons of the time in Edinburgh, Dr. John Moore, the father of the hero of Corunna, and several others. The author's work has been conscientiously done; and he has produced a work of uncommon interest, well got up, and containing some excellent portraits.

WINSLOW'S MAD HUMANITY (b)

THIS book is written for the general public, and the argument, or *raison d'être* of the author is, that a question which has so often been forced upon the notice of the House of Commons—viz., the alleged alarming increase of insanity, calls for the instruction of the public on the matter. When the author proceeds to assert in the teeth of opposite statements by official authorities in the three kingdoms—England, Scotland and Ireland—that the increase of insanity is real and not apparent, we must express the doubt whether he really is a safe guide in the matter for the general public. He admits that he differs from the Commissioners in Lunacy; but he gives no data—merely a general statement—in support of his contention. Dealing with the causes of insanity, the author gives us the stereotyped psychic and physical causes as if they were distinct and definite factors with a direct potency of their own. Causation is not quite so simple a question as he would have the general reader believe, and many potent influences

(a) "The Chemistry of Daily Life." By Dr. Lassar-Cohn. Translated by M. M. Pattison Muir, M.A., Fellow of Gonville and Caius College, Cambridge. London: H. Grevel and Co. 1899.

(b) "My Inner Life." By John Beattie Crozier. London: Longmans, Green, and Co.

(a) "Robert Burns and the Medical Profession." By William Findlay, M.D. Paisley and London: Alexander Gardner.

(b) "Mad Humanity." By L. Forbes Winslow, M.B., D.C.L. London: C. A. Pearson, Limited.

are left out of account in his calculation. Heredity is left out of account altogether. The *"Strain of Life"* is belittled as a cause, but a few pages further on we are told that the solution of the problem is to be found in "our own life of constant agitation, locomotion, and restlessness." The author treats of many matters, old and new, especially old, and already more than thrice told, respecting lunacy; but his aim throughout is evidently to cater to the curiosity of the general reader, and to provide sensational pabulum. The book might, with advantage, be boiled down to a quarter of its present size, and much irrelevant matter left out altogether. It is by no means up to date in its information, and can only be regarded by means of its title, its examples of strange mental aberration, and its illustrations as of interest more to the morbidly curious than to the better class intelligence of the general public.

HISTORY OF MEDICINE (a).

In the preface the author draws attention to the fact that a second edition of the book has been called for within a year, and looks on the demand as an indication of the interest the medical profession takes in the history of the development of the healing art.

With all this we agree; but we wonder if the interest will be sustained if no better pabulum is supplied than this poor stuff.

The usual method of writing a history of medicine is to give a series of short biographical sketches of the men who advanced the progress of the science and art of medicine, men whose thoughts moulded the opinions of succeeding generations. This is probably the most interesting way and the most readable. It fixes great names in our memory, and we feel proud of the pioneer who hews his way through the jungle of prejudices and superstition illuminating the dark places with the lamp of science. The fault in this method is that it too often ignores the extrinsic circumstances that so largely influence medical thought. We think a good history of medicine should combine both methods. The masters of medicine have always reflected the spirit of the age to which they belonged. Medicine, like other sciences, has been promoted and retarded by the prevailing spirit of the age, and from time to time men have become prominent who were unworthy of high place, and whose influence was inimical to the science.

The narrator of history should note the evil influence of the incompetent quite as carefully as he tells the vivifying influence of the divinely inspired.

Holding these views, we come to examine this book of Dr. Park, and we confess to a feeling of utter disappointment. He seems to have provided himself with some petty biographical dictionary, and to have arranged his little biographical sketches chronologically, and placed the product before the profession as an epitome of the history of medicine. We are all the more surprised at this, for the author publishes a list of the principal works consulted for the making of his book; works rich in information. Yet the author's volume seems little better than a filter which has retained the dregs and allowed the generous wine to escape.

In the first ninety pages the history of medicine among the Hebrews, Egyptians, Orientals, Chinese, and early Greeks is told. And as the reader finishes the pages he is forced to acknowledge that he has learnt nothing of the wonderful impetus to Greek medicine that resulted from the conquests of Alexander the Great; nothing of the introduction of Indian drugs into Greek practice, nothing of the evil influence of the science of the Chaldean astrology, nor of the influence for good of Babylonian clinical observation.

We search in vain for any account of the fall of the great school of Alexandria. What was the fall of that great school due to?

Phœnicia and Carthage, with their daring navigators and great commerce, very materially promoted the science and art of medicine; and the fact is not even mentioned.

(a) "An Epitome of the History of Medicine," by Roswell Park, A.M., M.D., Professor of Surgery in the Medical Department of the University of Buffalo. Second Edition. Philadelphia, New York, Chicago: The F. A. Davis Company, publishers. 4899.

Of the early days of Christianity, when its disciples, wishing to accentuate their separation from the Heathen, the Jew, and the Moslem, ignored the laws of sanitation, and looked on plagues of their own creation as Divine punishments, the author seems ignorant of its evil influence. We get platitudes and generalities when we seek concrete facts.

The sick Christian sought not a physician. He sought in Divine mercy a remedy, and to a cleric he told his grief, trusting the clerical experience to relieve both psychical and physical ills. Greek science was forgotten and the writings of the great masters, effaced as far as might be by pumice-stone. The parchment, became the palimpsests for the lives of saints, the great majority of whom retarded sanitation in their own day, and who are happily forgotten in ours.

The strength of the age of superstition lay in the homocentric theory, so firmly believed in that to doubt it was to incur the penalty of death. The stars rose and set to warn or encourage. The whole firmament it was believed was engaged in influencing the most trivial of human affairs. Science could not make progress in such an age. Here and there some few lovers of truth sought out natural causes for supernatural seemings, and the lamp of science was not wholly put out. Of these students of nature were the founders of the University of Salerno, and how it tells us of the effect of superstition on the Christians of the period to learn that none of them had hand or act in the glorious work. The Commonwealth of Amalphi protected the University in its early days from its Christian enemies, more particularly from those who felt instinctively that in the light of truth their insulting practices would be too manifestly absurd to live.

The rise of Moslemism, the capture of Constantinople, and the Crusades did much to promote medical science. The cleanly, sober, educated Moslem made the Christian, in time, ashamed of his filthiness, his drunkenness, his ignorance. The wealthy traders of the Italian commonwealths soon came to copy in their buildings the light, airy, well-ventilated homes of the Moslem, and in time the Northern Barons dwelt in a house, not a dungeon, and swept out the stinking mass of rushes and excrement that littered the baronial hall. Gunpowder finally swept those dens of disease and vice from the land, and its civilising influence indirectly promoted medical progress.

The rediscovery of glass and brickmaking revolutionised the conditions of social life; the mud hovel was replaced by a brick house, the materials of which readily lent themselves to the beautiful architectural design of the glorious days of Elizabeth. The homes of the people now became light and dry.

How the fearful plague of black death in England improved the condition of the peasant and promoted better tillage, draining of marishes, the getting rid of malaria, the lengthening of the average of life is not even referred to.

Superstition was dying out, the poor preachers of Wycliffe were going through the length and breadth of the land inculcating reason, and a little later Reginald Scott showed once for all the absurdity of crediting poor, feeble old women with the power of sending sicknesses.

Dr. Park misses altogether the influence of Caliphate on medicine. He refers in no way to the scrupulous cleanliness of the Arab surgeons in dressing wounds; the well-lit, well-ventilated hospitals; their children's hospitals; their insistence on fresh air and light, and on suitable clothing and personal cleanliness. We to-day are doing no more than reverting to the surgical maxims of the Western Moslem, and even now our hospitals have nothing comparable to the enclosed *plazas*, with their fountains, palm trees, and covered walks. On light bamboo frames suitably covered, the patient too ill to walk, was carried into the open air, where he was waited on by nurses. In those Moslem hospitals fevers were treated by cold water douches and baths, and in the hot plains of Spain fans were kept constantly at work to renew and cool the air.

Ferdinand swept the Moslem from Spain, and with

them went all that made the country great. The treasures which their sobriety and industry accumulated were dissipated in the wars of Charles and Philip, and the science taught in their universities made possible the deeds of her navigators.

The most casual reader of modern medicine must feel that the discovery of America had a great influence on medicine, if for no other reason than that it spent a blow to authority—liberated thought.

How the study of chemistry and of mathematics influences medicine is almost untold. In this connection we should expect to find honourable mention of Priestly and Beddoes, to whom we are really indebted for modern anesthetics.

We cannot give further space to pointing out the many deficiencies of the book. It may, however, assist our readers to find that the author includes among great men of the past Barnaby Cooper, "who achieved an eminence that is only dimmed by that of his uncle (Sir A. Cooper)." Sir B. Brodie, is also included, a man who did more to stay the progress of surgery than any other surgeon: every page of Brodie's writings tells of his lack of surgical knowledge. He was one of the sycophants of the "boosing" class, whose incompetency for the honourable position he was elected to became very evident on his promotion.

Guthrie is also included. We may charitably conclude Dr. Park never read the "Commentaries."

John Bell is dismissed in a few lines, no mention is made of his opening the cavities of the body or teaching E. McDowell. Ireland fares badly. Bellingham, who describes the "sledge hammer" pulse, wrongly called Corrigan's in the MEDICAL PRESS is omitted. The Brothers Griffin, whose book on spinal diseases is so often copied, and so seldom acknowledged, are unnamed. O'Hallaron, the pioneer in cerebral surgery, the pupil of Percivall Pott and friend of John Hunter, is not even named.

The discoverer of the membrana Jacobi, who as a boy was elected a member of the Royal Society for original research, is unnamed.

Mackeever who removed successfully eighteen inches of the ileum from a woman in the beginning of the century, finds no place.

Kane, whose investigation of the composition of white precipitate powder, which preceded Gerhardt's studies in the formation of substitution products, and laid the foundation for the production of synthetic products, is ignored.

Mary Donnelly's wonderful Cæsarean operation performed in a little Irish town more than one hundred years ago, is worth mention if only to show that necessity develops unexpected powers.

Of lesser faults time and space forbids our writing. We may, however, mention that Willis is mentioned in connection with the "circle of Willis" alone, and of Astruc the historian, simply records that he was a syphilographer. This of the man who equalled Erasmus in learning, and Luther in boldness of expression.

Literary Notes and Gossip.

PART III. of "The Catechism Series" (E. and S. Livingstone, Edinburgh) contains examination questions in the practice of medicine, with answers. This method of instruction had its vogue many years ago, at a time when Sandford and Merton came to the fore. It appears that it is still appreciated by students, as some of them are said to be anxious to level up their knowledge and remedy any blanks. For the really industrious this little book will be but of scant value.

UNDER the title "Newer Remedies" (Blakiston, Philadelphia) Dr. Virgil Coblentz has compiled a handy little synopsis of remedies of more or less recent introduction. He gives synonyms, sources, methods of preparation, taste, solubilities, incompatibles, properties, and doses, thus constituting a reference manual for physicians and pharmacists. The number and varieties of these new agents are calculated to inspire awe, but fortunately

many, if not most of them, are stillborn, and are not likely to vex the soul of the prescriber. This is a convenient book to have in one's library, for it does occasionally happen that one experiences the need of some information concerning one or other of the new remedies that have come to stay.

WE have just received the volume—January to June, 1899—of Braithwaite's "Retrospect of Medicine," forming the 119th volume of the series. The high reputation of the latter for usefulness is well maintained in this latest issue. The abstracts, as usual, are excellently done, and the busy practitioner is thus provided with a rich mine of information concerning all the newest facts and features in medical science. In addition, the volume contains a complete general index of the previous issues from 113 to 118 inclusive.

OF the "Hygiene of the Mouth," by R. Denison Pedley, F.R.C.S.Ed., L.D.S., we have little to say by way of praise. The author's object is professedly to call attention to the serious effects upon the general health of dental diseases, and to show how such diseases may be controlled or prevented. We are not satisfied that he has done either, and his English is open to criticism, as, for example, when he speaks of "preventative disease," "disqualified from," &c. As a plea for closer dental supervision the book may pass muster, but as for the rest the less said the better.

THE "West London Medico-Chirurgical Journal," though comparatively young in years, has shown a steady and indeed remarkable upward growth. The last number, for instance, contains no less than 127 pages of matter, headed by the brilliant Cavendish lecture on Cerebro-spinal Fever, by Professor Osler, a full abstract of which has already appeared in our own journal. The West London Medico-Chirurgical Society is conducted on decidedly progressive principles, and its representative organ deserves the success to which it has attained.

Vectis is an elegant and artistic weekly illustrated journal of literary and general interest for the Isle of Wight, and is edited and conducted by a medical man, who can boast also of being poet, novelist, and dramatist. Dr. Dabbs, the family doctor of the late Lord Tennyson, is, judging from his journal, a versatile and talented member of our profession. The current number of *Vectis* is of peculiar interest to us, as with it is presented an admirable portrait of the late Dr. J. Sinclair Coghill, who has done so much to perfect our knowledge of the treatment of phthisis, and who has laboured so earnestly to develop the National Consumption Hospital at Ventnor.

STUDENTS will welcome any aid to the study of *materia medica* for examination purposes. Much time and labour is often spent in getting sufficient grip of this tedious, though all important subject. Miss Giffen's method of tabulation, ("The Student's Practical *Materia Medica*," E. & S. Livingstone, Edinburgh, 1899) will be helpful to many, and the mastery of her little book of about 90 pages would give the student a foundation on which he could build a future efficient knowledge of *materia medica*. It does not attempt to treat of the action and uses of drugs, and must, therefore, be used as an aid to, and not as a substitute for, the larger text books.

THOSE of our readers who cultivate a knowledge of shorthand may be interested in the fact that Vol. III. of the Phonographic Medical Library contains a very interesting monograph by Sir Wm. Thomson, F.R.C.S.I., on "Some Diseases of the Rectum and Anus." Of the lecture proper we prefer not to speak, inasmuch as, in shorthand matters, we see as through a glass, darkly. We note that it is considered desirable to give the headings of chapters and of sub-divisions in ordinary type, which appeals to our sensorium much more directly than do the ornately artistic hieroglyphics which (form) obscure the light shed by the author on an important chapter of practical medicine.

Few new books on medicine and surgery are published during what is called "the dead season," and the present is no exception. A couple of large atlases, however, have made their appearance, one under the authorship of "Dr. Donald Mackintosh, a "Skiagraphic Atlas of Fractures and Dislocations," and an "Atlas of Urinary Sediments," by Dr. Reider, translated by Dr. F. C. Moore. A good many new books and new editions are promised for the autumn. That by Sir Wm. Broadbent on "Diseases of the Heart," being nearly free of the Press, and a revised edition of Rose and Carless's popular "Manual of Surgery," is announced to be ready next month.

THE publication of Dr. Walsh's "Röntgen Rays in Medical Work" in 1897 marked an epoch in surgery. It was the first book that enabled the surgeon to practically grasp the technicalities of Professor Röntgen's marvellous discovery and to fix the date of a new departure. That such a work was needed, is evidenced by the appearance this week of a new and greatly improved edition, the science becoming so rapidly progressive that it had to be mostly re-written and illustrated with many additional plates. As hon. secretary of the Röntgen Society since its foundation, the author has had exceptional opportunities, of which he has not been slow to avail himself, if we may take the book before us as an example.

THE College of Physicians of Philadelphia ask us to announce that the Fifth Triennial Jenks Prize of five hundred dollars, under the deed of trust of Mrs. William F. Jenks, will be awarded to the author of the best essay on "The Various Manifestations of Lithæmia in Infancy and Childhood, with the Etiology and Treatment." The prize is open for competition to the whole world, but the essay must be the production of a single person, and be written in the English language, or, if in a foreign language, accompanied by an English translation. It should be sent to the College of Physicians of Philadelphia, Pennsylvania, U.S.A., before January 1st, 1901, addressed to Dr. R. C. Norris, Chairman of the William F. Jenks Prize Committee. Each essay must be typewritten, distinguished by a motto, and accompanied by a sealed envelope bearing the same motto and containing the name and address of the writer. No envelope will be opened except that which accompanies the successful essay.

ANTI-NATAL therapeutics are beginning to find a place in our medical literature, their obvious aim being to produce a race strong both in intellect and physique. The consideration of "Health in the Nursery," by Henry Ashby, M.D., F.R.C.S. (Longmans), is of importance, and a book such as that before us is welcome as being a help in the right direction. The first chapter, "Training in the Nursery," will commend itself to most thoughtful minds. Such training, if carefully followed, would do much to lay the foundation of habits which would make the future man or woman a more reasonable and a healthier being. The book is readable, being simply and clearly written and requiring very little medical knowledge to enter fully into its teaching. It may be safely recommended for wide circulation among those who have either medically or otherwise, the charge of the young.

THE critic is disarmed in presence of a work on the ubiquitous baby which has reached a sixth edition. Such is the fate that has overtaken Mrs. Langton Hewer's "Our Baby" (Wright and Co., Bristol). This is not merely a guide-book for mothers and nurses in respect of the alimentation of infants, the advice given is for the most part such as we can cordially approve, but the author adds a good deal of very sound counsel concerning the physical and moral training of the child, to which the thoughtful will give due heed. The author is not always quite up-to-date, witness the advocacy of "arm-to-arm" vaccination, a practice which has deservedly fallen into disrepute. As in most works of the kind there is a large amount of technical information which cannot by any chance prove useful to the average

mother or nurse, but after all there is no objection to describing diseases provided the reader be warned against attempting diagnosis and *a fortiori* treatment.

New Medical Appliances.

THE "ALLENBURY" MILK PASTEURISERS.

THE evidence that has gradually been accumulated during the last few years of the wholesale spread of disease by milk has brought into prominence the importance of effectually sterilising this valuable but unstable article of food before using it as such. Simple boiling, though a procedure not to be despised, has been shown to fall short of perfect sterilisation, and it is necessary to educate the public in the technique of the process, whereby milk may be effectually divested of any disease-producing organisms which it may and often does contain. The public, or the intelligent section thereof at any rate, are very willing, very anxious, to acquire this knowledge, and this has created a demand for a simple, cheap, and trustworthy apparatus for the purpose. Such an apparatus is the "Allenbury's" Milk Pasteuriser.

It consists of a jacketed vessel, or container, with a supporting plate for the milk cans. These having been filled with milk, the container is filled with *boiling* water, the cover placed in position and the apparatus left undisturbed for about half-an-hour. The milk is then ready for use, but it is of advantage at this stage to pour cold water through the container so as to secure prompt refrigeration of the milk.

When this process can be carried out on *fresh* milk, effectual sterilisation is probably secured, but it must be clearly understood that this treatment of stale or partially decomposed milk, though it may kill all living organisms, will not convert it into a commendable article of food, seeing that the milk still contains the soluble products of bacterial activity—the so-called toxins, which account for so much of the gastro-enteritis of infants. In any case it is desirable to consume the milk as soon as possible after sterilisation, or else the process should be repeated. Full directions accompany the apparatus, which ought to find a place in every household mindful of their health.

Notices to Correspondents, Short Letters, &c.

✉ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a distinctive signature or initials, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

DUNCAN, T.—Our correspondent has no redress, assuming that his statements are correct. The law presses very hardly in cases such as he describes.

SPES writes:—"I should be obliged if you could tell me if there is any publication which gives the composition of quack medicines."—Our correspondent would probably find all that he wants in "Exposures of Quackery," published by the Savoy Press, 115, Strand, W.C.—Ed. M.P. & C.

HISPANIA (London).—Our correspondent had better write to us again in October, when the vacation is over, since the present meteorological and other conditions are not favourable for the discussion of the matter referred to in his letter.

FLIES AND TYPHOID FEVER.

THE Medical Commission, appointed to inquire into the cause of the severe epidemics of typhoid in the American camps during the war with Spain, reported that the disease was undoubtedly spread by flies, and that had it not been for these insects there would have only been a few isolated cases.

VISITOR (Eastbourne).—Our correspondent should bring the facts under the notice of the Medical Officer of Health for the town.

S. T. O. (Birmingham).—The clause appears to us to be quite a reasonable one; it would, of course, be binding upon both parties.

SENEX.—Our correspondent has omitted to enclose his private card.

ALPHA (Luton).—The district which you describe is evidently in urgent need of a competent Medical Officer of Health. It is ridiculous to expect any efficient health administration from a busy medical practitioner, who is paid a small sum to look after the sanitation of a large and sparsely populated area. Indeed, as a rule it is against the interests of such an official to interfere with the property of the councillors who govern the district. Until a radical reform is made by the legislature there will be little prospect of anything like a national system of public health. Combined sanitary areas and security of tenure of medical officerships appear to offer the best way out of the difficulty.

EXOPHTHALMIA (Beds).—Try thyroid gland: five grains of desiccated gland at first once a day, increased up to three or four times that amount. Regulate dose by effects. The "trinity of symptoms" in exophthalmic goitre are the enlarged thyroid gland, the "Vardy" eyelid, and the emotional, irregular heart. We fear your case is advanced too far any prospect of permanent relief, but treatment should not be given up on that account. The best palliative measures are those that deal with general nutrition, especially in the form spoken of at the outset of our reply.

A BACTERIOLOGICAL TRAGEDY.

A GAY Bacillus, to gain him glory,
Once gave a ball in a laboratory.
The fete took place on a cover glass,
Where vulgar germs could not harass.
None but the cultured were invited,
(For microbe cliques are well united)
And tightly closed the ball-room doors,
To all the germs containing spores.
The Staphylococci first arrived—
To stand in groups they all contrived—
The Streptococci took great pains
To seat themselves in graceful chains,
While somewhat late, and two by two,
The Diplococci came in view.
The Pneumococci, stern and haughty,
Declared the Gonococci naughty
And would not care to stay at all.

—*Texas Med. Journal.*

ERRATUM.—In report of International Ophthalmological Congress in our last issue, for Dr. Sattler (Leipzig) on Non-cataract read Iron-ataract, i.e., caused by iron splinters.

Vacancies.

Armagh Union.—Medical Doctor (temporary). Remuneration two guineas per week. Application to Clerk of Union. See Advt.

Berry Wood Asylum, Northampton.—Senior Assistant Medical Officer for five years, unmarried. Salary £200, rising to £250, with board, lodging, and washing, &c.

Birkenhead Children's Hospital, Birkenhead.—House Surgeon. Salary £75 per annum, with board, residence, and laundry.

Dundee Royal Lunatic Asylum.—Medical Assistant.—Salary £100, with board and lodging.

Durham County Asylum, Winterton, Ferry Hill.—Assistant Medical Officer, unmarried. Salary £120, with apartments, board, and attendance.

East London Hospital for Children.—Two Clinical Clerkships. Also House Surgeon. Board, residence, &c., are provided, and an honorarium of £25 at the completion of six months' approval service.

Horton Infirmary, Banbury.—House Surgeon and Dispenser. Salary £80 per annum, with board and lodging.

Manchester Children's Hospital.—Junior Resident Medical Officer for six months, unmarried. Salary at the rate of £80 a year,

with board and lodging. Secretary, Dispensary, Gartside Street, Manchester.

Manchester Hospital for Consumption and Diseases of the Throat and Chest.—Resident Medical Officer for the In-patient Department, Bowdon, Cheshire. Salary £80 per annum, with board, apartments, and washing.

Metropolitan Hospital, Kingland Road.—House Physician, House Surgeon, Assistant House Physician, and Assistant House Surgeon. Appointments tenable for six months. House Physician and House Surgeon £40 a year. Assistant House Physician and Assistant House Surgeon £30 a year.

New Ross Union.—Analyst to the Board of Guardians. Salary £10 per year. Applications to Clerk of Union. See Advt.

Parish of St. Giles, Camberwell.—Assistant Medical Officer, either sex, for one year. £50 and apartments, board, and washing.

Royal Halifax Infirmary.—Assistant House Surgeon, unmarried. Salary £50 per annum, with an extra allowance of £9 2s. 6d. per annum, and residence, board, and washing.

Royal Surrey County Hospital, Guildford.—Resident House Surgeon. Salary £80, board, residence, and laundry provided.

St. Luke's Hospital, London, E.C. Clinical Assistant for six months. Board and residence provided.

Stroud General Hospital.—House Surgeon. Salary £90 per annum, with board, lodging, and washing.

Western General Dispensary, Marylebone Road.—Second House Surgeon, unmarried. Residence at the Dispensary. Salary £75 per annum, with board and residence, and 10s. a month allowed for washing.

Appointments.

ADAMS, E. W., M.B.Lond., House Physician to the Northern Hospital, Liverpool.

BEST, P., L.S.A., M.B.C.S., L.R.C.P., Medical Officer for the Third District, Penzance Union.

DOHERTY, J. D., M.D.Edin., House Surgeon to the Northern Hospital, Liverpool.

FEGAN, JOHN F., L.R.C.S.Irel., L.A.H.Dub., Medical Officer to the Oldcastle Dispensary.

JOHNS, A. T., M.B., B.S., M.D.Dub., Medical Officer for the Gropedy District, Banbury Union.

KINSEY-MORGAN, A., M.B.C.S., L.R.C.P., House Surgeon to the Royal Victoria Hospital, Bournemouth.

KNOWLES, Miss B., M.B., B.S.Lond., Second Assistant Medical Officer at the Waterloo Road Workhouse, St. Matthew, Bethnal Green, vice Mr. G. Gatenby.

MEACHER, J. H., M.B.C.S., L.R.C.P., Mr. Medical Officer for the Second District, Bodmin Union.

MOORE, S. C., M.B., Ch.B.Vict., Assistant House Surgeon to the Northern Hospital, Liverpool.

OLD, J. E. S., L.S.A.Lond., House Surgeon to the Branch Hospital of the Seamen's Hospital Society in connection with the London School for the Study of Tropical Diseases.

REID, HUGH, L.R.C.P. & S. Edin., Dispensary Medical Officer of the Montaigne District, near Portadown.

UTLEY, C. H., M.B.Lond., Assistant Medical Officer at the Infirmary, Salford Union.

Births.

BEAN.—On August 23rd, at Clapham, the wife of Louis C. Bean, M.B.C.S. Eng., L.R.C.P. Lond., of a son.

BLAKE.—On August 22nd, at "Sunnybank," Shoot-up Hill, West Hampstead, the wife of Percy L. Blaker, M.B.C.S., L.R.C.P., of a son.

DAVIDSON.—On August 20th, at Riverside Lodge, Teddington, the wife of Harold Davidson, M.B.C.S., L.R.C.P., of a son.

DUGON.—On August 22nd, at 17, Iderton Road, Rotherhithe, the wife of Francis Dugon, M.B.C.S., L.R.C.P., of a son.

FEGAN.—On August 22nd, at Fair View, Westcombe Park, Blackheath, S.E., the wife of J. H. C. Fegan, L.R.C.P., M.B.C.S. Eng., of a son.

STOCKER.—On August 23rd, at Pinehurst, Clevedon, the wife of E. Gaved Stocker, M.B.C.S., L.R.C.P., of a son.

WILDING.—On August 22nd, at The Hawthorns, Hindley, Wigan, the wife of Walter F. W. Wilding, M.B.C.S., L.R.C.P., M.O.H., Hindley, of a daughter.

Marriages.

BABINGTON—LONG.—On August 22nd, at Christ Church, Down Street, London, W., by the Rev. A. Babington, father of the bridegroom, Stanley Noel Babington, M.B.C.S. Eng., L.R.C.P. Lond., to Sarah, second daughter of Thomas Long, of Bracknell.

MARTIN—BARTLETT.—On August 22nd, at the Baptist Church, Westgate Road, Newcastle-upon-Tyne, Albert M. Martin, M.B., of Dene House, South Shields, to Mary Winifred Bartlett (Maimie), younger daughter of J. M. Bartlett, Esq., of Newcastle-upon-Tyne.

Deaths.

CHARLES.—On August 21st, at Bradmore Road, Oxford, David Hughes Charles, M.D., J.P. for co. Tyrone, in his 81st year.

CLARKE.—On August 23rd, at Honiton, Lillian Sophia Clarke, wife of George Saunders Clarke, M.B.C.S. Eng., L.R.C.P. Lond., aged 31.

FITZ-HENRY.—On August 22nd, at Wellington Hotel, near Camberley, Edward Henry Fitz-Henry, M.D., formerly of Mentone and Waterloo.

GLOVER.—On August 18th, at Blandford Road, Chiswick, William James Schoedde Glover, M.B.C.S., L.S.A.

HADOW.—On August 24th, at 4, Clarence Place, Penzance, Gerald Elliot Hadow, M.A., M.B., after a long illness, aged 23 years.

LATHAM.—On August 23rd, at Enderlie, Torquay, after four days' illness, Diana Frances, elder daughter of the late Peter M. Latham, Esq., M.D., Physician Extraordinary to the Queen, aged 64.

ALBUMINURIC RETINITIS. (a)

By SAMUEL WEST, M.D., F.R.C.P.,

Assistant Physician to St. Bartholomew's Hospital; Senior Physician Royal Free Hospital.

In its typical form albuminuric retinitis is characteristic and pathognomonic. Yet upon many important points the statements of different authorities are very conflicting and difficult to reconcile.

Kidney diseases fall into two great groups according as dropsy is a prominent symptom or not; and the kind of albuminuric retinitis most frequently met with in these two groups will, I think, be found to be different.

The lesions of albuminuric retinitis consist in white patches, hæmorrhages, and exudation variously combined with each other, and lastly quasi-inflammatory conditions.

THE EXUDATIVE (INFLAMMATORY-EXTREME) FORM.

In this form the changes are widespread and extreme, and closely resemble what is seen in other forms of acute neuro-retinitis. Dropsy is not very common in granular kidney, so this form of albuminuric retinitis but rarely occurs in this disease, but is more frequently met with in the other group, viz., that of parenchymatous nephritis.

Complicated as the question is, we seem to be justified in drawing these conclusions:—That this form of albuminuric retinitis is of an exudative inflammatory type, that it is probably of toxic origin, and related rather to the cellular degeneration than to the interstitial fibrosis.

If the view I am expressing prove to be correct, it follows not only that the kind of albuminuric retinitis which prevails in the two forms of renal disease is different, but that it has a different diagnostic value in the two cases. In parenchymatous nephritis the diagnosis of the disease is obvious, and the albuminuric retinitis is an interesting by-phenomenon only. In granular kidney the diagnosis may be uncertain until all doubt is dispelled by the discovery of the characteristic eye-changes. It is to this group that some of the cases of albuminuric retinitis belong. On the other hand many more of these cases in pregnancy belong to the degenerative group, and are evidence of granular kidney.

Puerperal eclampsia occurs in either form, in the former rarely without dropsy, and in the latter not infrequently without.

THE DEGENERATIVE FORM.

The degenerative form of albuminuric retinitis consists in white patches and hæmorrhages. Of these the most characteristic are the white patches. There are, I believe, two kinds of white spots, the one forming bright spots glistening like fish scales, the other not so glistening or so sharply defined, but woolly in appearance. The former are the result of degenerative changes, and their brilliancy depends upon the presence of minutely refractive oil-drops or even cholesterine crystals; the latter are often small

patches of exudation only. The former are of slow development and unlikely to disappear at all or only slowly and after a long time; the latter, however, may come and go rapidly.

In parenchymatous nephritis the diagnosis of renal disease is usually obvious whether there be white spots or not. In granular kidney, however, the diagnosis may be uncertain until the eye-changes are discovered. The white spots, whether they be really exudative or degenerative, have therefore in granular kidney a diagnostic value which they do not possess in the other forms of nephritis. Early as the white patches or degenerative changes are, they precede and result from still earlier changes in the vessels (silver-wire arteries).

Although the silver-wire arteries are no doubt ophthalmoscopic evidence of the vascular degeneration, as are also the hæmorrhages and white spots, it does not follow that the vessels necessarily show the white silver-wire streaks before the other lesions are visible.

Of the hæmorrhages which occur in albuminuric retinitis it is not necessary to say much. Similar hæmorrhages may occur in both the exudative and in the degenerative forms, but they are probably produced in different ways in each case. In the latter they are the consequence of the vascular degeneration and are due to the rupture of the diseased arteries in the retina, as in other parts of the body. In the former they are generally due to the rupture of over distended veins, consequent on the pinching to which the veins are subjected as they pass through the swollen disc.

Paradoxical as it may seem, it is in the so-called extreme forms of albuminuric retinitis, or as I should call them, the exudative forms, that the prognosis both in respect of life and in respect of sight is not nearly so grave as it might appear to be, for if the kidney mischief recover the eye-lesion may resolve and the sight be completely restored. If, as in pregnancy, the cause return, the retinitis may also return, and with each succeeding pregnancy the prognosis in respect of sight of course becomes worse.

In respect of life the prognosis is that of the renal disease, and all that I think the albuminuric retinitis in these cases does is to show that we have a form of parenchymatous nephritis to deal with of a somewhat unusual severity. The white patches of granular kidney rarely disappear; but they are often present without much defect of sight.

The ophthalmoscopic changes in the vessels are important as evidence of an arterial degeneration which is a visual evidence of the risks to which the patients are subject from the disease of the vessels elsewhere, e.g., in the brain.

SUMMARY.

I may bring this communication to a conclusion by summing up the facts which I think justify the drawing of a sharp distinction between the two forms of albuminuric retinitis, the degenerative and the exudative. They stand in strong contrast with each other in the following respects:—

1. Of the form of disease with which they are usually associated: the degenerative with granular kidney, the exudative especially with parenchymatous nephritis.

(a) Abstract of Paper read at the Annual Meeting of the British Medical Association at Portsmouth, August, 1899.

2. Of their nature and cause: the exudative being inflammatory and probably toxic in origin, the degenerative consequent on vascular changes and more or less mechanical in origin.

Of sight: for the exudative, even in the extreme forms, may recover, with little or no defect of sight, but with the degenerative, if there is any impairment of sight, it is usually progressive.

4. Of diagnostic value: the exudative being an interesting by-phenomenon of chronic parenchymatous nephritis, an affection the existence of which is obvious enough, while in granular kidney the degenerative often makes the diagnosis certain in cases which have been hitherto obscure.

5. Of risk to life: for while in both cases it indicates a grave form of renal disease which may of itself prove fatal, in granular kidney it indicates in addition all those dangers to which arterial disease exposes the patient.

I think, therefore, that the distinction is not only justified by the facts, but explains many of the apparent contradictions which are made by different authors.

ON CHRONIC FOLLICULAR PHARYNGITIS. (a)

By ROBERT H. WOODS, M.B., F.R.C.S.,
Throat Surgeon to the Richmond Hospital, Dublin.

CHRONIC pharyngitis, or, as it is sometimes called, clergyman's sore throat, is one of the commonest affections of the upper respiratory tract. It is not as its alternative name would imply, confined to public speakers, nor does it in my experience occur with much greater frequency among people with whom public speaking is an essential part of their profession.

Though the best marked examples are to be found among adults, and in men rather than women, yet it is met frequently among the young of both sexes. That the disease has long been known and repeatedly described is not surprising, since a large portion of the region involved can be well inspected without any other aid than that of a common spatula.

Patients generally complain of the throat being sore and tired, and the voice is a little husky especially after prolonged speaking or singing, and occasionally of slight difficulty in swallowing, this difficulty being more pronounced when the bolus is small, as when saliva is swallowed, than when large as at meal times. Arising from a feeling of mucus being constantly present there is a persistent desire to hawk and clear the throat, hardly less annoying to their neighbours than to the sufferers themselves. They find the state of the weather largely influences their comfort, a moist, cold day being less tolerable than a warm dry one.

On inspection the pillars of the fauces, soft palate, and posterior pharynx wall, and in severe cases the larynx, are seen to be redder than normal. The superficial vessels are dilated, and the mucous membrane slightly roughened. These appearances are better seen at the upper part of the throat, especially on the faucial pillars than further down. The lymphoid follicles on the posterior pharynx wall are enlarged and prominent, and it is this item among the physical signs that lends to the disorder its distinctive name. In some cases a thick red cord of swollen tissue runs from above downwards on both lateral pharynx walls immediately behind the tonsil, disappearing from view behind the palate above, and hidden by the tongue below, quickly tailing off in the mucous membrane. The cause of these well-known conditions

has been variously attributed to repeated attacks of acute inflammation, overstraining of the voice, excessive smoking, unhealthy occupations, especially those where employés are crowded in an impure and dusty atmosphere, &c.

The treatments adopted have been, in addition to getting rid as far as possible of the apparent cause, thermal or chemical cauterisation of the hypertrophied lymph follicles on the posterior pharynx wall, and of the masses on the lateral wall, avulsion of the follicles by sharp forceps, brushing the pharynx twice a week for several months with astringents, such as six per cent. silver nitrate or zinc chloride, glycerine of tannin, borax and a host of other antiseptics and astringents, and finally an infinity of gargles varying from plain water to elaborate concoctions containing a great variety of drugs, in the hope that if one did not do good another might.

In my earlier days as a laryngologist I conscientiously tried all the more rational of these methods, and though I often succeeded in temporarily curing the patient, I know of no case treated by me on these lines which remained free from the symptoms for more than a few months; nor was it until a considerable number of these cases had passed through my hands that I saw I was only treating an effect and not a primary cause.

In my opinion and experience, chronic follicular pharyngitis is, in the vast majority of cases, the result of nasal obstruction, or, more immediately, mouth breathing.

It will be convenient at this place to say a word or two about the functions of that neglected, though highly important member, the nose.

By the majority of people, and among them are some whose duty it is to know better, the nose is looked upon merely as the organ of smell and as an aid to the sense of taste. The nose is not an organ but a member, and smell is the meanest of its duties. Its really important work consists in preparing and modifying the air, so that it may be fitted for entry into the delicate respiratory passages below, and this it does in three ways.

First, by warming the air. Anyone who has dissected a nose can hardly fail to have been impressed with the extent and richness of its blood supply, a richness out of all proportion to the need of the part, and which finds expression in the ease with which its lining membrane is made to bleed. It is, indeed, a beautiful hot water system, where the heat of the circulating fluid is transferred to the air with which it is in contact, the rate of transference being increased from what it would be were the nose a single plain tube, by the extra surface exposed, not only on both sides of the septum but also on the turbinated bones, especially the inferior and middle. So perfectly is the air warmed, that elaborate and careful experiments have shown that by the time the air reaches the naso-pharynx its temperature is practically that of the blood.

Second, by moistening the air. The watery mucus with which the walls of a normal nose are constantly smeared, readily gives up its moisture to the passing air, the great blood supply to the soft parts aiding in two ways; promoting by its heat the surface evaporation, and by its constituents feeding the secreting parts with the necessary watery elements. Experiment has here too shown that the air when it reaches the naso-pharynx is all but saturated with moisture.

Third, by filtering the air. If impure dusty air be blown through a tube the sides of which are smeared with glycerine or any similar substance, it will be found, especially if the tube is not quite straight, that it comes out pure at the other end, the dust being caught and held by the slimy surface.

This is precisely what happens in the nose. The moist surfaces act as a most efficient trap for solid

(a) Read before the Medical Section of the Royal Academy of Medicine in Ireland, April, 1899.

particles suspended in the inspired air; thus they are first caught and afterwards expelled in the periodical blowings to which all normal noses are subjected.

We have only to look at the motes in the sunbeam, in order to be convinced of the great importance of this factor in the struggle for health, especially to us who live in cities and crowded places where purity is the rarest attribute of the atmosphere; and especially also, when, as our bacteriology teaches us, these motes are so many rafts for bacteria, pathogenic and saprophytic.

There are reasons, too, for suspecting that the nose exercises a destructive effect on bacteria. This has not yet been put beyond dispute, but waiving this claim, there is more than evidence enough to show that on *a priori* grounds the efficient discharge of the functions of the nose must be of prime importance to the welfare of the respiratory tract.

If, from any cause, the nose is obstructed, breathing must be carried on through the mouth, and inasmuch as the alteration of the inspired air from contact with moist warm surfaces, is largely a purely physical process, and that the air will go on absorbing both heat and moisture until its saturation points are reached, and that these cannot be attained in the mouth, it follows that the throat is compelled to take on the functions of the nose, and part with heat and moisture sufficient to satisfy the demands of the air, at the same time freeing it from dust. It follows, too, that the first, or highest, portion of the throat is where we must expect the severest effect of the abnormal condition to evidence itself, for this is the part struck by the stream of air when at its driest, coldest, and dustiest.

In these cases of pharyngitis from nasal obstruction, when the cause is as just shown primarily a mechanical one, it is to be expected that if any portion of the mucous membrane were unexposed to the irritation of the air that part would remain normal. And this I have found to be the case. If the back of the pharynx be illuminated, and the soft palate raised with a probe, it will be seen that the pharyngeal wall above the level of the palate is unaffected; while immediately below that point where it is unprotected by the palate, the other condition obtains, the line of demarcation being quite sharp and coinciding with the lower level of the palate.

I regard this fact as of great importance in the proof of the condition being a result of nasal obstruction.

In obedience to the demand for heat and moisture from the pharynx, the superficial vessels dilate, and by a continuance of the irritation for a sufficient time, a chronic low form of inflammation is set up, mucus is poured out, and as it yields its moisture it thickens and becomes more tenacious, and *pari passu*, the mechanical irritation of its presence and the difficulty of its removal increase.

The comparative narrowness of the nose enables a forced expiration to send the air through its cavity at a velocity sufficient to expel mucus, however, tenacious, with comparative ease; but the pharynx, being more open, allows of no increase in the velocity of the air, and to overcome the difficulty and dislodge the glutinous material, the pharynx is voluntarily narrowed during forced expiration, and hawking results.

The difficulty in swallowing is contributed to in two ways.

The presence of tough mucus provokes acts of swallowing. Now the exertion required varies within limits in adverse ratio to the size of the substance to be swallowed, and therefore the smallness of the bolus demands that the effort must be vigorous in order that the wave of contraction may not ail to lay hold of and push the matter before it. If the mucus were more watery a single effort might

entirely remove it for the time, but when it is remembered that its natural toughness is increased by evaporation, and that it is adherent to the walls by which it is secreted, it is not hard to understand how futile must be the attempts to remove it, though from its tickling, those attempts must necessarily be made. The muscles of swallowing must therefore become overworked and painful, and a condition in many ways analogous to writer's cramp established.

Again, the inflammation of the pharynx wall, above referred to, is not always confined to the mucous membrane, but extends into the muscles, and this, no doubt, contributes to the discomfort attending deglutition in many of these cases.

That the larynx, even when affected, is not always complained of, is intelligible, since the brunt of the evil is borne by the pharynx, and the further down we go the more nearly is the air to the ideal condition, and therefore the less it irritates the surfaces with which it comes in contact. When the larynx is involved, as it always is in severe cases, the conditions which obtain are almost identical with those described in the pharynx. The vocal cords are injected, thickened and nodular, and impurity of the voice, if not actual hoarseness, results.

The evil effects of smoking, in this, as in most other affections of the throat, have, I am convinced, been greatly over-estimated.

I do not believe that the pipe or the cigar are ever in themselves injurious. When consumed in the ordinary way, the smoke never passes the cavity of the mouth, for during the act of sucking the soft palate and the dorsum of the tongue must necessarily be in contact, and so the throat is completely cut away from the influence of the fumes. The case of the cigarette is different, for cigarette smokers, not content with the amount of absorption of the active principles of the drug that goes on in the mouth, inhale the smoke, to the very great detriment of the air passages. In the same way pipe and cigar smoking, if done by a number of persons in a small room may, by creating a fog, prove harmful both to the non-smoker and the smoker, but with proper ventilation, and *a fortiori* in the open air, the practice can have no hurtful effect on the throat of either.

Among the causes to which chronic pharyngitis is attributed comes that limbo of disorders, gout. I have more than once had congestion of the throat pointed out to me as the sole evidence of this disease. That gout may possibly cause such a primary condition in the throat I am not prepared to deny, but I have seen no case in which this physical sign, even when looked on as an evidence of gout, was not associated with some form of nasal obstruction, or which was not relieved by nasal treatment.

In some cases of chronic pharyngitis, as in all other abnormal conditions of the throat, the nose should be thoroughly examined.

This advice is usually given with the tacit implication that it can be followed by anyone. For my own part, I must say that I found it many times more difficult than either retinoscopy or laryngoscopy. Examination through the nostril, simple as it looks, demands for its efficient performance the power of concentrating the attention on one retinal image only, and the most perfect control over accommodation in the observing eye in order to see anything at all, and when seen the character, size, and position of the object and its relation to neighbouring structures have to be determined.

I do not here intend to treat obstructive diseases of the nose at all exhaustively, but inasmuch as the radical cure of chronic pharyngitis involves, in general, putting the nose in working condition, a few words on the subject will not be out of place.

The causes of nasal obstruction are sometimes

anatomical, more often pathological. Among the anatomical causes, spurs, or deflections of the septum, are in adults very frequently met with.

In these cases the obstructed side is small, and the tissues thin and atrophic, while the opposite side is large, and the tissues hypertrophic, the result partly of overwork, and partly of repeated acute inflammation to which such cases are liable. These are as a class best treated by removal of the offending portion with a knife, or if the cartilage be calcified, a fine saw.

Post-nasal growths are, of course, among children the most frequent causes of obstruction, and it will always be found that whether the child complains of the symptoms of chronic pharyngitis or not, the physical signs will be present in the old standing cases.

This in itself would be sufficient to justify the removal of adenoids, even if their presence were not baneful for so many other reasons; but in this immediate connection it is well to point out that in an unrelieved case, though it is usual for the growths to atrophy and leave the passage clear in early adult life, stenosis still remains. The cause of this is easily seen. If, for any reason, a member of the body is not used for many years, it will, if the owner be an adult, atrophy, or, if a child, remain undeveloped.

Examples of this are common enough. It will be sufficient to remind you of the diminutive proportions of the leg in a neglected case of hip disease, where the thigh has been allowed to ankylose in a position such as to prevent the foot touching the ground. The leg and foot are quite healthy, lacking nothing except exercise in order that they should be developed as on the opposite side; but physiological idleness has effected an anachronism, and we have a child's leg on a man's body. In a precisely identical way, the persistence of nasal obstruction from adenoids, enforces in an unrelieved case a similar physiological idleness with the parallel result of a child's nose in an adult's head. Partly, therefore, from the fact that the nose in such cases is not equal to the demand put upon it when at length the post-nasal space is clear, and partly no doubt from the difficulty of shaking off a bad habit acquired in infancy, and practised night and day during adolescence, mouth breathing persists with its attendant evils.

A trained eye can recognise such people in the street.

Examination of such a person shows, in addition to the characteristic facies flattening from side to side of the nose and the nasal fossae, prominence of the front teeth, an abnormally high and narrow arch to the bony palate, diminished distance between the molars of the right and left sides, chronic pharyngitis, and other signs which we need not stop to mention.

Chronic follicular pharyngitis in people with an abnormally small nose is a very difficult condition to cure, because we are more or less limited by the outer bony wall of the nose from enlarging the air space to the requirements of the individual. But still much can be done by sacrificing a small quantity of the tissue on the outer wall, especially the soft parts covering the inferior turbinated bone.

Chronic hypertrophic rhinitis is readily recognised by the swollen and turgid condition of the inferior turbinated bodies.

With it is commonly associated post-nasal thickening and its resultant post-nasal catarrh. These are best treated with the electro-cautery, by laying down a linear scar along the enlarged bodies which, when it contracts, will brace up the tissues out of the way, and so free the air space. In severe cases reduction of the hypertrophied bodies with the electric snare, may be called for.

One wall only of the nasal fossa should be cauterised at a time, otherwise two points may adhere

and synechia result, leaving matters worse than before. With ordinary care this should not occur, but I have known the accident happen.

As a fairly common cause of chronic pharyngitis, polypi of the nose deserve mention. The distress of the primary disease is, however, so great that the throat is rarely complained of. Their removal should be accomplished with the snare, and not the forceps.

The snare properly used removes them more completely; it leaves the normal tissues untouched, it does no violence to the bones of the nose, and therefore the patient suffers but a fraction of the pain and none of the damage caused by the forceps. Furthermore, it is not as well known as it deserves to be, that when the polypi have been well snared the judicious use of the electro-cautery on the ground from which they grew will often effect a radical cure.

To those of us who, having seen polypi removed by the forceps in the old way, have ourselves adopted the snare, it is astonishing that the more improved method should not have beaten its once respected predecessor out of the field, but unfortunately the forceps in many places is still the only instrument used.

In a number of cases of chronic pharyngitis, however, examination of the nose shows no obstruction, the patient is able to breathe quite naturally, and yet, what I venture to call, the characteristic symptoms of nasal obstruction, are present. Inquiry will elicit that these patients snore, or waken in the morning with a dry tongue. Some of them may deny it, but if you send them away and ask them to take observation on themselves, they will tell you at their next visit that your suspicion was well founded, and that they find their nose so stopped at night that they cannot breathe through it without a sense of suffocation, but after getting out of bed a few minutes suffice to make it quite clear again.

This story has been told me so often that the condition must be a very common one. We have here evidently an engorgement of the erectile tissue of the nose; whether, as seems most likely, it is due to mechanical congestion, the result of the head being lower in the horizontal position than the upright, or whether it is a vasomotor phenomenon predisposed to by some local condition, and determined by sleep, I cannot say; but at any rate we have the condition, and fortunately the cure too. The electro-cautery properly used along the inferior turbinated bodies, will, when the scars heal and contract, i.e., in from six to eight weeks, most probably cure the patient. If in a couple of months he still complains, it shows too little has been done. I think I may without offence call this condition nocturnal obstruction.

Though the vast majority of cases of throat irritation result from nasal obstruction, yet there are still to be found a few in whom this condition, still the result of not using the nose, is unassociated with obstruction. There are teachers or others who talk a great part of the day, often under very unhygienic conditions, such as overcrowded and dusty school-rooms. The special liability of teachers to this form of sore throat, is due to the fact that people, when speaking inspire through the mouth, even when the nose is quite free, and when this is done persistently the throat sooner or later suffers, for the effect is of the same kind, if not to the same degree, as when the nose is stopped. The remedy is simple, provided the nose is healthy. The patient should be directed to speak deliberately, and, instead of gulping in the air, to inspire through the nose between the sentences, a habit not difficult of acquisition.

In conclusion, let me say that the gravity of diseases of the nose in general is very much underrated. We have in chronic pharyngitis a perfectly definite and tangible effect of abnormal nasal conditions on the respiratory passages. It is only step

by step that we can hope to father effect on cause. The necessity for rhinoscopy in throat disease was only pointed out a few years ago, and it will not be surprising if some of the chest troubles now believed to be idiopathic should, when our knowledge is riper, prove to be preventible by the endowment of a functional nose.

We have the very best grounds for believing that phthisis is often caused by the inhalation of pulverised tuberculous sputum, and for my part I am convinced that the victims of consumption would be much fewer if normal noses were more common.

THE GENERAL PRINCIPLES OF SANITATION. (a)

By SIR WILLIAM HENRY PREECE,
K.C.B., F.R.S.,
President Inst.C.E., &c.

AFTER some introductory remarks, the President said:—

The human frame is a little world in itself, inhabited by different nations and by different races, born, living, and dying in us as we do on this earth, perhaps in peace, generally in war, and fortunately for us not yet free from cannibalism. There are many millions of living micro-organisms flourishing in every body in this hall. As long as we are in health they live in peace, and we remain unconscious of their existence; but let some external bacterium force the ramparts, then there is bitter war, and either the invader is destroyed by our friends, or we ourselves succumb to cholera, typhoid, diphtheria, or to the growth of some other inimical but victorious bacterial race.

The principal object of modern sanitary science is to develop this new empire of bacteria, and to discover its races and their peculiarities. The chief function of the sanitary engineer is to defend the human frame from its invisible and insidious external foes.

The greatest sanitary engineer the world has ever known was Moses. The Book of Leviticus is a treatise on hygiene. For 3,400 years the world stood still, and only one race followed the doctrines and teachings of that Great Master. The Christian threw his tenets to the wind—the Mahometan, to his great benefit, has continued to practise some of his principles to the present day. The Jew remains faithful, and is the healthiest and longest-lived type of humanity. The doctrines of Moses can be summed up as the objects of sanitation to day:—I. Pure air. II. Pure water. III. Pure food. IV. Pure soil. V. Pure dwellings. VI. Pure bodies.

There are three important principles underlying all practical applications of sanitary engineering: (1) Energy or the ability to do work; (2) chemistry or the power to transform matter; (3) life.

(1) The principle of energy affirms that this capacity for doing work is a fixed quantity in the universe. Energy can neither be added to nor destroyed. It can only be transformed from one kind of motion to another—material or ætherial. The motion of matter can be converted into the motions of the æther or *vice versa*. Sound, light, electricity, and heat are mere forms of energy.

(2) The principle of chemistry affirms that the quantity of matter in the universe is also a fixed quantity, and that it can neither be added to nor destroyed. Matter is reducible to about seventy elements, and it is found in three states, solid, liquid and gaseous. All that the chemist can do is to

transform matter from one state to the other, and from one compound to some other by linking, delinking, and relinking the atoms and molecules in various combinations.

(3) The principle of life is beyond our comprehension. All we know is that, by expending energy on matter, life in the very tiniest germ that moves, so small as to be beyond the reach of the senses, performs with unfailing accuracy the duties of the engineer and the chemist. Life plays some important function in the economy of Nature, and if we cannot divine the reason of its existence, it is because we are able to read the book of God only as through a glass, darkly.

I.—PURE AIR.

The supply of pure air to those who breathe it, is the object of ventilation. Moses did not legislate for ventilation, for the Israelites dwelt in tents, but he showed how to prevent the pollution of air by the decomposition of refuse, for he ordered it to be carried out without the camp into a clean place, and there be burnt. We are only now learning to follow Moses' lead, for refuse destructors are quite a modern and up-to-date "invention." We are even utilising their heat for the generation of steam for electric lighting generating stations, and we are thereby economising waste, the highest function of the engineer.

In cold climates where dwelling indoors and with closed windows is imperative, it is essential for health that air vitiated by breathing should be periodically replaced. Thus the whole theory of ventilation is circulation of air maintained at a proper temperature, for cold air may be injurious. The British legislature has taken care that lunatic asylums, workhouses, and gaols shall be provided with proper air space per person, and supplied with effective ventilation, but churches, chapels, theatres, and other places where people most do congregate are neglected and remain sinks of discomfort. In a dining-room where I recently dined with four gas burners alight, taking each burner as equivalent to five persons, the cubic space was 160 ft. per head, and this air remained stagnant for two hours. In a third class railway carriage, when full, it is only 47 cubic feet per passenger.

The problem is to promote thorough circulation without draught, and without affecting the temperature or the humidity of the air. Is the circulation to be promoted by natural or by mechanical means? Is the outlet to be at the ceiling or floor level? Is the pure air to be forced in by pressure, or the foul air to be drawn out by vacuum? Is the admitted air to be warmed in winter and cooled in summer, and how? Is it to be filtered and freed from dust? Every system of ventilation needs intelligent supervision. What is the standard of purity of air? Some define it by the quantity of carbon dioxide it contains. This should not exceed 8 volumes per 100,000, but there are other and greater impurities in used up air that cannot be defined.

Electricity has fortunately come in to simplify our difficulties. It has the great merit that in the glow-lamp it does not vitiate the air. It supplies us also with a convenient form of energy for artificial ventilation.

II.—PURE WATER.

It is a moot question whether absolutely pure water is healthy, and hence we have not yet secured a universally accepted definition of practical purity. Is purity to be determined by the quantity of organic matter in suspension or in solution, by its hardness, by the amount of micro-organisms it contains, or by the amount of injury it inflicts on human life? Sir Edward Frankland found in Thames water 160,000 bacteria per cubic centimetre. Good drinking water should, however, contain not more than twenty bacteria per cubic centimetre.

(a) Abstract of inaugural address delivered before the Sanitary Institute Congress at Southampton.

Rivers are polluted not alone by the excretions of humanity, but by the refuse of trade and of manufacture. Pollution has not yet been made a penal offence. The Chinese are in advance of us. In that country, sewage—the chief cause of pollution—goes to benefit the land, not to pollute the river.

Getting good water and maintaining it good is the chief work of the sanitary engineer. Polluted water is now purified and softened *mechanically* by sand filtration, an imitation of nature; *chemically* by precipitation and by the action of vegetation; and *biologically* by the chemical activities and cannibal habits of living organism.

While two or three gallons per head are sufficient for simple dietetic purposes, many more gallons are used for watering streets and gardens, flushing closets and drains, extinguishing fires, washing carriages and for general stable work, and factory purposes. The consumption of water is thus very variable. While in most English cities it rarely exceeds 25 gallons per head per day, in New York it reaches 60, and in Philadelphia 90 gallons. It would seem as though carefully purified water is misused when it is applied to such public purposes as to lay dust, to generate steam, and to flush the public sewers—processes which lead to repollution without any benefit whatever. Should there not be a duplicate supply, one for domestic and the other for public purposes? This is already done at Richmond and St. Helens. Sea-water is used at Great Yarmouth and Bournemouth. Indeed, the use of sea-water as an auxiliary supply for public purposes deserves the serious consideration of all local magnates at our seaside resorts. It is well worth the consideration of the London County Council, for it would practically more than double the Metropolitan supply for domestic use. It is better for them to go to the sea, which is near to them, than to go so far to gallant little Wales that does not intend, in spite of its gallantry, to let London rob it of its water. Birmingham and Liverpool have taught it experience. The Thames Valley ought to supply London with excellent drinking water for the next 50 years—even with its present works. The death-rate in London, a good practical standard of the purity of water, is well below the average.

III.—PURE FOOD.

It was in the regulation of the food supply of the Israelites that Moses displayed his profound knowledge of hygiene. It is by adhering to these regulations to the present day that the Jews live such healthy lives. His division of beasts into clean and unclean was mainly a separation of the digestible from the indigestible.

Parliament does not prescribe our daily food, but it does legislate against impure food. Cold storage has rendered possible the importation of meat from our most distant colonies, and few of us know whether the tender saddle of mutton on our table is, as asserted, from Wales or from New Zealand.

The most important and general form of food is milk, for it affects all ages and both sexes, especially young children. The danger from milk is infinitely greater than from meat. It is unfortunately a great medium for the transmission of the germs of disease, especially of the bacillus of typhoid fever and of tuberculosis. Unclean milk is too common, and, unfortunately, inspection and examination of cows, cowsheds, dairies, and milk cans is, in many districts, thoroughly inefficient. It is not at present under the control of the proper sanitary authorities.

The milk business of this country, especially of the metropolis, is fortunately falling rapidly into the hands of large public companies, who are well able to protect themselves, and who do protect their clients, the public, but in small urban and country districts it remains in the hands of the farmer, often a member

of the very local authority that should enforce regulations which it is his own interest to ignore. It is a misfortune that the co-operative system of Denmark has not been introduced into this country. There a large central dairy is managed by a small board, elected from the contributing farmers, who are scattered over the district, and who send to this establishment their milk, to be inspected, measured, and treated, and each of whom draws his *pro rata* share of the profits. Curiously enough their best customer is England.

Legislation, as affecting adulteration of food, the importation of meat, the sale of drugs, fruit, fish, &c., is probably ample. It is the enforcement of regulations, the control of supervising powers, the appointment of inspectors that is weak.

IV.—PURE SOIL.

The purity of the ground upon which our dwellings are erected, upon which our plants, fruit, and vegetables are grown, where our kine and flocks feed, where we take our daily walks, upon which the air that we breathe rests, and whence our water is often drawn, depends upon the care exercised by ourselves upon the disposal of our excretions and refuse. Many beasts of the field are wiser in their generation than many a human race, even of the present day. Carnivora cover up their dung with earth. The cat, though domesticated, retains this instinct. The badger has its run to its own latrine. The fox will not pollute its own hole. The Persian, it was reported, polluted even the rooms at Buckingham Palace.

Moses, in prescribing "a place without the camp, whither thou shalt go forth abroad," enjoined the covering up of all excreta with earth. This was the first known disposal of sewage, and was a natural and effective system.

The system of treating and disposing of sewage can be considered under three heads:—1. Mechanical. 2. Chemical. 3. Biological. The first system deals with the removal of all the organic and inorganic matter in sewage. The second includes various plans for the precipitation of solids, the filtration of liquids, and the formation of artificial manures. The third extends the second to the aeration of the clarified sewage, so as to secure the nitrification of the organic matters in suspension or solution by bacterial agencies, and then to enrich the land, and to purify the effluent for further use.

Chemical treatment is well illustrated in the case of London, where it has hitherto been in operation without any supplementary process, but where recently some important experiments have been conducted to determine the conditions that would justify the introduction of the biological system. The crude sewage is admitted into precipitating tanks, where it is treated with lime and sulphate of iron in definite quantities. These cause the chemical transformation of the elements and compounds in solution to form solids, which with those already in suspension slowly settle by gravitation as *sludge*. The *effluent* flows into the river at Barking and Crossness. Over 2,000,000 tons of this wet sludge are conveyed every year 50 miles away to sea. The improvement of the Thames has been very marked. It is a misfortune that the sludge cannot be made a useful and saleable article, but the most careful inquiries have shown that it is practically impossible with such an enormous population—now over 5,000,000—to treat it economically in any other way.

Mr. George Chatterton is carrying out works for Dublin similar to those in London, but the sludge will have to be carried away only 10 miles into the Irish Channel. It now goes direct into the river Liffey, which flows virtually as an open sewer through the city, causing an almost intolerable nuisance.

Unfortunately, sewage farms, as a rule, do not pay. It will be a great relief to get rid of them. We have seen during the past Session of Parliament how the Camp Sewage Farm at Aldershot has been violently attacked. The new biological treatment may modify the views of this Board. It is a department extremely well advised and ably administered, and we may be sure that if the experimental success of the new system be followed by a sound, practical result, it will carefully safeguard the public requirement and health.

The new biological treatment is a return to Nature. "Nature never yet betrayed the heart that loved her." That wonderful micro-organism that has eluded man's observation for all these millions of years is divided into two classes—(a) bacteria which work with oxygen, and (b) those which do not. The sewage first reaches the settling-tanks, where the inorganic matter, such as sand and grit, is deposited. The albuminous and organic matters and urea which are found in all sewage are then transformed by bacteria into forms of ammonia. The decomposition of animal and vegetable matter, which is invariably due to the action of these bacteria, is thus utilised to liquefy organic solids, and in this way to simplify their removal. Other bacteria gradually, in special filters, transform the ammonia, by the aid of oxygen and other elements present, into nitrates. The process of filtering is intermittent, for air is essential to maintain the supply of oxygen to the nitrifying bacteria; but an air blast, in some cases, is used to maintain a continuous action. The nitrifying effect is enhanced if the air be warmed to about 100 degs. Fahr. The filters must have porosity and resistance to flow to retard the passage of the sewage through them, for time is essential for the bacteria to grow and to act. In sandy ground Nature does this, but on clay formation, coke-breeze, and even coal, is found to be very effective. In this way bacteria first liquefy the solid matters in the sewage, and then nitrify them, simultaneously purifying and enriching the affluent, and preventing the formation of that wasteful product, sludge. The biological system has clearly come to stay. It is, however, still in the experimental stage.

Biological methods may be divided into two classes:—(a) Those which deal with sewage, clarified by precipitation and filtering; and (b) those which attempt to deal with crude sewage. The former plan appears so far to be the most effective. The second plan has the merit of greater simplicity; and if the action of the different bacteria be simultaneous, and not successive, it may possess the method of practicability, as well as of economy. A Royal Commission is now sitting considering the whole question.

The London County Council are making valuable experiments at Crossness, and their conclusions will have a far-reaching influence in the country generally. Pasteur, the father of the germ theory, taught us how the yeast germ produced fermentation, how another micro-organism takes up oxygen from the air and unites with the hydrogen of alcohol to form acetic acid and water. The actual mechanical processes through which bacteriolysis pass, expending energy, transforming matter, and promoting life, form one of the most interesting pages of the history of evolution ever narrated. The intermittent benefit of filtration was discovered in the laboratory by Frankland in 1870.

V.—PURE DWELLINGS.

People suffer not alone from ignorance, but from carelessness and filth. The Legislation of recent years by which local authorities can improve the dwellings of the working classes, and inspect and control common lodging houses, has had a beneficial influence upon the community by clearing away slums and con-

structing new streets. But unfortunately authorities are hampered by the restrictions of the Act of 1890, and they are checked by the greed of vested interests. Edinburgh, by spending £560,000 on improving the housing of the poor, has brought down the death rate from 28 to 17 per 1,000. The responsibility of maintaining pure dwellings rests now very much with the sanitary authorities.

VI.—PURE BODIES.

Broadly speaking, every section of this address has reference to health. Hygiene is the most important knowledge for everyone to possess, but it is, perhaps, the least acquired. The wealth and strength of a nation rest with the health of its people. Is it not something to have reduced the death-rate 30 per cent., and to have added at the same rate to the growth of the nation?

Cleanliness is next to godliness; this is the key-stone of hygiene. Moses prescribed cleanliness above everything. Lepers were to be washed, shaven and cleansed with blood, cedar wood, scarlet and hyssop. Their garments were to be rent and burnt. They were to be isolated outside the camp. Their houses were to be shut up, disinfected and cleaned, and even in serious cases to be pulled down, the materials removed out of the city and destroyed by fire. The Cleansing of Persons Act, 1897, is a great lever in the direction of cleanliness, but much remains to be done.

CONCLUSION.

The chief function of the Sanitary Institute is not only to disperse knowledge but to dispel ignorance. The resistance to progress is not so much ignorance itself, but the determination to remain ignorant. There are none so obstructive as those who will not learn. "What was good enough for my grandfather is good enough for me," is the cursed dogma of the British stay-at-home. Travelling knocks this nonsense out of him, for he sees that Americans and Germans are beating him in the race.

Step by step engineering progress and scientific research are bringing us face to face with the grand generalisation that Nature is only another term for God, that Nature's laws are His thoughts, and that everywhere, the stars in their courses and the bacteria in their operations follow one fixed and settled design.

"One God, one law, one element,
And one far off divine event,
To which the whole Creation moves."

ALCOHOLISM IN ITS RELATION TO HEREDITY. (a)

By GEO. ARCHDALL REID, M.B., C.M.Ed.,
Honorary Physician to Nazareth Home.

DRUNKENNESS is unquestionably a terrible thing, but it is as yet unproved that parental intemperance afflicts the offspring in such wise as to produce in them an increased craving for drink, not to mention such effects as insanity and epilepsy. It is true that the offspring of drunkards are sometimes epileptic or insane and very often of intemperate habits, but to attribute these evils to the influence of parental indulgence acting through heredity is to confuse *post hoc* with *propter hoc*. Every drunkard has in his nature a marked capacity for enjoying alcohol and in addition to this a keen memory of the delights conferred by previous acts of drinking. This primary capacity for enjoying alcohol is an inborn factor, and thus, in harmony with the teachings of biological theory, it may be transmitted. The other element, however—viz., the keen memory of the delights conferred by

(a) Abstract of paper read at the Annual Meeting of the British Medical Association, Portsmouth, August, 1899.

acts of drinking—is a later trait, an acquired character, and this cannot be transmitted to the offspring of the drunkard. The question of the transmission of acquired traits has been one of the burning questions of the age, and though the whole plant and animal world had been ransacked yet no single instance of the transmission of acquired characters has been proved. *A priori*, therefore, it is most unlikely that the acquired effects of alcoholism—in the forms manifested to us in drunkards—are transmitted to the offspring. Men differ very much from one another in the depth or intensity of their craving for drink. Some men are abstainers or are temperate because their innate desire for drink is small or practically *nil*. Others, *per contra*, relish drink so greatly and crave it so greedily because having once had experience of it a very intense pleasure is felt and strong desire experienced. It is from the ranks of the latter that the army of drunkards is recruited. Between these two extremes are all shades of drinkers. As individuals thus differ, so do nations and races. The Jews and Southern Europeans generally are very temperate, while the Northern European races are much less temperate. Races and nations crave for alcohol in inverse proportion to their past familiarity with it. Present-day savages, such as those of America, Australia, and Polynesia, who have never manufactured alcohol (as history shows) even in dilute form, delight so intensely in this novel drink that, given the opportunity, they drink to extinction. Other savages, such as those of Africa, who have been able to manufacture alcohol in dilute solutions and in limited quantities, though more intemperate and less able to resist drink than Europeans, are much less prone to such extreme intemperance than the savages of North America. These facts establish the conclusion that the inclination to alcoholic excess is for a given race in inverse propor-

tion to the past racial experience of alcohol. The race that has been longest familiar with alcohol is generally found to be the most temperate. This shows that the effects of intemperance as acquired by ancestors are not transmissible, for were it the case then the constant accumulation of such effects generation after generation would render the race that had longest used drink the most inclined to drunkenness. As regarded epilepsy and insanity, it may be argued that these may appear in the progeny of non-inebriates as of inebriates; and if it be further objected that the offspring of inebriates are thus afflicted in higher proportion, it may be retorted that it is precisely from those having a primary tendency to epilepsy that one would expect tendencies towards inebriety. The tendency to epilepsy, however, may not manifest itself as such, though in the children it may appear as distinct epilepsy. The drunkenness of the parent will mask his epileptic tendency which, however, may reappear in the child in more obvious fashion and without inebriety being the causal element in determining epilepsy in the offspring. The temperance reformer's plan of abolishing drink is not the true method of reform. Were such a procedure to come into force for a time the result would be that the race now removed from alcoholic selection would revert to the ancestral type in which the tendency to excessive drink was greater, and directly the opportunity recurred would drink almost to extinction, like savage man unacquainted in the past with alcohol. Nature's plan has, on the other hand, brought about the result that all communities which were anciently given to drink are now relatively sober, and that in proportion to their past sufferings from drink. Were alcohol withheld some other stimulant or narcotic, such as opium, would take its place—as is shown in the present history of certain Eastern nations.

INVALID'S CONVERTIBLE BED-SUPPORT AND CHAIR.

A NEW BED SUPPORT.—"THE CARLOTTA."

By E. BLAKE, M.D. ABERD., M.R.C.S. ENG.

I SHOULD like to draw the attention of the profession to an ingenious invention (see illustration above) by a patient, for supporting the back after an illness. It is a clever contrivance, and is calculated to diminish the misery of invalidism and to promote comfort during convalescence.

This invention consists of a wooden frame in four pieces, which can be put together on the bed, round the patient, the side pieces being near the centre and for the length of 4 ins., 6 or 7 ins. in height, diminishing to 1 in. at each end; the four pieces of the frame are made fast together by thumb screws.

To each of these side pieces at the part where they are highest are attached by a double hinge two wooden bars, rising vertically, one forming one side of a frame for the

seat and one the frame of the back of the bed support, which can be raised or lowered by means of legs hinged to the under part of the frame of the seat and the back, and which fit into racks cut in the side pieces of the first-named frame. The bars forming the frame of the seat and the back of the bed support are respectively connected and strengthened by curved iron rods, fitted into grooves, fixed under the ends of the wooden bars of the seat and back. The seat of the bed support is formed of strong webbing, bound at each side with leather, and having three leather straps strongly sewn on each side. This webbing being passed under the thighs of the patient lying on the bed, the straps are hooked on each side by means of holes on to brass pegs fixed in the sides of the bars forming the seat of the bed support, the legs under the seat are raised to the desired height, and the thighs of the patient are thus raised slightly off the level of the bed. The back is formed of webbing in the same way as the seat, and passed under the shoulders of the patient and attached in a similar way to the bars of the back. The supporting legs under the back are then adjusted, and the patient will be found to have been raised into a sitting position without any exertion on his part.

An important point in the formation of the seat is the arrangement of the webbing, by which a space is left between the seat and back, in order to avoid any pressure on the spinal column of the invalid, and which also allows for convenient use of the bed-pan without any change of position. A movable headpiece, consisting of a slight frame of wood covered with canvas, slips into sockets screwed on to the ends of the bars of the frame of the back. Arm rests of wood are connected by thumb screws, one end to the side of the frame of the seat, the other to the side of the frame of the back, and being of two pieces hinged together, move with the movement of the frame of the bed support when raised or lowered. A wooden rest for the feet is slung from the front of the first-named frame by narrow bands of webbing, adjustable as to length, by a buckle. The bed support would be made in dimensions proportionate to the size of the invalid.

A comfortable bedroom chair can be made by placing this bed support on an invalid bed table made in proportions to carry it. The invalid bed table is made with a top which can be raised or lowered, and with legs which can be unscrewed for packing, and which are fitted with ball castors.

The invalid bed table is merely an adjunct of the bed support, and is not claimed as a novelty. It is claimed for this invention that this bed support can be used on any bed, and provides a simple and effective mode of raising into a sitting position a helpless invalid. That by means of this arrangement of the seat it provides a comfortable chair in bed which also allows of attention to the needs of the invalid, or of his being lifted out of bed without change of position. This is the only kind of back support, with which I am acquainted, that can prevent the constant tendency of the patient to glide down towards the foot of the bed. Messrs. Arnold and Sons, of West Smithfield, E.C., are the manufacturers.

Clinical Records.

A CASE OF PARATHYROID TUMOUR CAUSING SYMPTOMS OF MALIGNANT DISEASE OF THE LARYNX — OPERATION AND RECOVERY. (a)

By PHILIP P. W. DE SANTI, F.R.C.S.,
Senior Assistant Surgeon and Aural Surgeon to Westminster Hospital.

A RETIRED major, æt. 58, was sent to me by Mr. Eliot, of Southampton, in June, 1895, with a history of ten months' persistent hoarseness, some stridor, and a "braisy" cough. He had had his chest examined by Dr. Mitchell Bruce, but nothing abnormal was discovered. There was no pain or dysphagia, no expectoration, and no loss of flesh. The patient denied syphilis.

On examination I found marked impaired mobility of the right vocal cord and limited abduction. The right vocal cord was uniformly red and swollen, there was no ulceration or neoplasm visible, no glands palpable in the neck; old scarring of right face and cheek suggestive of old syphilis; voice very hoarse and feeble. I considered it most probable that the case was one of early malignant disease of the larynx with an alternative of syphilis or mediastinal tumour pressing on the right recurrent laryngeal nerve. I ordered rest of the voice, no smoking, and iodide of potassium.

In September, 1895, the patient's voice was almost a whisper. He had gone downhill rapidly, having lost much in weight. The right carotid artery pulsated visibly and seemed pushed forward by a smallish, indefinite, probably glandular swelling deep in the neck and about the level of the second or third ring of the trachea.

In December, 1895, the swelling in the neck was smaller, the voice better, the right vocal cord a little more movable, and there was a gain in weight.

During 1896 the patient was in very fair health, had gained weight, the voice though hoarse was stronger, and the swelling in the neck movable, softer, and more defined; the right vocal cord was *in statu quo*.

In February, 1899, patient had an attack of flatulence and dyspepsia; this was shortly followed by difficulty in swallowing solids and later, liquids. He lost flesh rapidly, half a stone between February 6th and March 29th. At the same time a very marked increase in the size of the cervical swelling was noted. There was regurgitation of food and sensation of obstruction at the level of the cricoid cartilage.

Examination of the larynx showed the right vocal cord more fixed but otherwise the same. I passed a No. 18 œsophageal bougie and met with some obstruction about level of upper part of sternum. No blood or pus on withdrawal.

The lump in the neck felt to be the size of a Tangerine orange. It seemed elastic and not stony hard. I took a grave view of the case, and advised exploratory incision in the neck, as I considered from the whole course of the events the main trouble extra-laryngeal.

I made an incision over the anterior border of the right sterno-mastoid down to level of sternum, and exposed a large tumour situate in the lower carotid triangle extending underneath the sterno-mastoid outwards and downwards under upper part of sternum and upwards to level of cricoid cartilage.

I carefully defined the tumour and found it encapsuled; the carotid artery and jugular veins were pushed far over to the outer side; the whole tumour was very vascular. I eventually clearly isolated it, the chief difficulty being with the right recurrent nerve which was attached to the tumour and flattened, and with the inferior thyroid artery. The right innominate and part of left innominate veins were exposed.

The œsophagus was distinctly compressed by the tumour; the latter had no connection with the thyroid gland, but there was some fibrous infiltration of the œsophagus opposite the seat of pressure.

A cross cut and partial division of sterno-mastoid had to be made to thoroughly get at the tumour. The right dome of the pleura, the right phrenic nerve, and the right subclavian artery were seen at the time of the operation.

Recovery was uneventful and swallowing powers improved almost at once.

Microscopic sections showed parathyroid tissue essentially innocent. The growth was encapsuled, and contained centrally a large cyst. The case is of interest because at first everything pointed to early malignant disease of the right vocal cord: i.e. the age of the patient, the uniform redness and impaired mobility of the cord, the hoarseness, and later the presence of a lump like a gland externally. On the other hand the duration of the trouble and its stationary condition did not resemble carcinoma. Later, i.e., February, 1899, everything again pointed to malignant disease, though more of the neck than the larynx.

The patient now, August, 1899, is in very good health, and his swallowing powers are excellent.

(a) Abstract of paper read before the British Medical Association at Portsmouth, 1899.

France.

[FROM OUR OWN CORRESPONDENT.]

PARIS, September 3rd, 1896.

VARICOSE ULCERS.

PROF. CHIPAULT read a paper before the Biological Society on the treatment of varicose ulcers by stretching the sensitive nerves of the leg. The nerve, he said, chosen for the operation, should be that on the territory where the ulcer was situated, and more particularly the internal saphena or the musculo-cutaneous nerves. The treatment of the ulcer itself consisted of one of two methods. If it were small he advised total ablation; if, on the contrary, it were extensive, which was generally the case, he counselled the use of the rugine to convert a foetid wound into a healthy one, and obtain its healing by appropriate applications.

ACNE VULGARIS.

M. Gaucher spoke on the nature and treatment of acne vulgaris, so frequently seen on the face of young persons. These pimples were comprised of papules or pustules. In theory, they were found everywhere where sebaceous glands existed; in reality, they were found in preference on the face, the neck, the shoulders, and the back; certain authors gave to it the name of juvenile acne. The element was a red papule with indurated base, painful and turning yellow in two or three days, the result of injection from without due to the presence of staphylococci. But this injection was not an absolute rule, for it did not exist in subjects who had not a natural tendency to suppuration. Consequently one of two things happened: the pustule broke, giving passage to a little pus, and disappeared without leaving a trace, or the pus dried up forming a crust which sometimes fell off, and sometimes left after it induration caused by retention of the inflammatory products. Miliary acne was constituted by small granulations of the size of a pin's head, the result of accumulation of sebum in the glandular cavity; enucleation, the only means of cure, revealed the presence of fatty matter and a few crystals of cholesterine. Punctuated acne was still more frequent; black points occupying the orifices of the sebaceous glands, composed of concrete sebaceous matter, and which owed their colouration to dust; it was the type of acne by retention.

The etiology of acne, in M. Gaucher's opinion, was lymphatism, and bad working of the digestive functions, which is generally accompanied with dilatation of the stomach.

The therapeutics of the affection were more simple than was supposed. No internal treatment could be considered as a specific for acne; ichthyol and cod-liver oil should be avoided; but the *regime* should be attended to particularly, fat as well as fermented aliments were hurtful, laxatives should be ordered frequently.

The external treatment consisted only in frequent washings with soap and water, and the application of sulphur ointment.

Germany.

BERLIN, September 1st, 1896.

DISCUSSION ON CZEMPIN'S PAPER ON MODERN MYOMA OPERATIONS.

MR. SIMMONS said that long before Landau, operators advocated separate ligation of the vessels in such opera-

tions, among others v. Herff, in a publication in the *Münch. Med. Wochenschrift*. Years ago he had had the opportunity of seeing v. Rosthorn operate, who had expressly said that he always operated in that way. In the vaginal method, when the ligaments were very tense, the clamps were liable to slip. In the face of several good methods he hoped that one would be able to say before operation whether the clamp or the ligature would be most suitable. In order to have a basis it was desirable that complete reports should be furnished, especially from Landau's Klinik, with technical details.

HR. DÜHRSEN said that the small walnut-sized myomata, that often caused the most pain, were the mesonephric. The expression "substituting" myoma (substituierendes myom) (Landau) was a very happy one, but the speaker did not think total extirpation necessary for them. This opinion was based on a case treated in 1895. A lady, an authoress, æt. 31, had an uterus reaching to the navel, and upon the retention of this the patient insisted, as she might possibly contract a marriage. He treated the case in such a way that a later examination showed a large and normal uterus, and the speaker believed that the authoress in her celebrated novel would not have been capable of its glowing diction if the uterus had been removed. He was opposed to the view of the necessity of extirpation in the case of mesonephric and mucous adenomata; the tumour could very well be cut out of the substance of the uterus, and the uterus and adnexa retained, and in the case of myomata not above the size of the first, by anterior celiotomy. That in many cases the important method of treatment by curettement had not been considered, lay in the fact that the myoma had not been understood. He was opposed to Landau's view as to the atrophy of the mucous covering. The speaker had seen myomata with quite "colossal" growth of the mucous surface. Here transient or even permanent good results might be obtained, as also by vaporisation. He dilated with laminaria, palpated the uterine cavity, curetted, and first satisfied himself that there was no malignant new growth.

Czempin was responsible for the idea that curettement stimulated the growth of myoma, but there were other stimulants, especially the menopause. Retrogression was rare in the menopause; rapid growth and degeneration frequent. His estimate of morcellement was higher than that of Czempin. In Péan's operation he ligatured the ligaments instead of clamping them, but no ligature material should be left in the abdominal cavity.

PUERPERAL ECLAMPSIA IN ITS PRESENT FORM.

This subject is treated, from a practitioner's point of view, in a pamphlet of forty pages, by Dr. Siegfried Flatau. By the term "eclampsia" is meant an auto-intoxication coming on during the reproduction process, which suddenly comes to an outbreak, its most important and striking phenomenon being a heightened excitability of the spasm centres. Of 100 cases 60 begin at or about the time of labour, 23 during the pregnancy, and 17 in childbed. Primiparae are preponderatingly attacked. Twin and triplet births predispose, and above all nephritis or the kidney of pregnancy. The affection leads to death in a relatively large number of cases, partly by apoplectic disturbances in the brain, by cardiac failure, oedema of the lungs, by pneumonia from swallowing, by sepsis. The prognosis of eclampsia in childbed is more favourable than that *sub partu*, and experience has shown com-

pletion of labour cuts off the attack in 85 per cent. of the cases; those cases are the most serious when the attacks commence early, when labour is slow and therefore in primiparæ. The prognosis is bad when the attacks follow in quick succession, and worse in those cases when the attacks continue after the birth of the child.

In cases where the attacks begin before the normal end of pregnancy the foetal mortality is, according to Schauta, 41·8 per cent. If the child is dead the attacks usually cease, but not always.

Of children actually born a large number die—between 20 and 40 per cent. Many factors, the more or less active treatment, the frequency of the attacks, &c., affect the death rate. It is probable that the child in utero suffers from the disease as well as the mother.

The pathological anatomy of the disease in the form of a completed systematically built up system was first presented by Schmorl. The lesion of the kidneys is generally very severe. The urine in 64 per cent. contains albumen or acid, the quantity diminished, and occasionally there is anuria. The kidneys contain fat emboli, characteristic hæmorrhages, and necrotic patches, in association with thrombi of the vessels, and the changes of parenchymatous or intestinal nephritis. *But there are cases in which there is no albumen nor, indeed, any coarse changes in the kidney.* Dilatation of one ureter is not rare. In the liver also there are hæmorrhages and necroses, in the thromboses of vessels, and fatty emboli; in the brain anæmia, oedema, with flattening of the gyri, and hæmorrhages, the latter often microscopic; in the lungs, besides thromboses and hæmorrhages, there are liver and placental emboli.

The fact first determined by Bouchard that the urine of eclampsia was three times less poisonous than that of healthy individuals, and, on the other hand, the certainly proved greater toxicity of the blood of eclampsia, raises the view that eclampsia is an auto-intoxication during the reproductive process, to the dignity of an axiom. What the nature of the poison (creatine, creatinine, carbaminic acid globuline?), and why it is formed and becomes active during pregnancy, form questions for further inquiry.

As regards therapeutics, the author lays great stress on a milk diet as a prophylactic, baths, diuresis, &c. If nephritis gravidarum already exists, interruption of the pregnancy should not be entertained.

During an attack the head should be placed on its side in order to avoid inspiration of saliva. The chief aim during an attack, viewing the case as one of auto-intoxication, is excitement of the se- and excretions, wet packings, sweatings, diaphoretic and diuretic measures; venesection is not a palliative only: it lowers the blood pressure, it prevents cedema of the lungs, it prevents apoplexies, but it acts ætiologically in removing along with the blood a portion of the toxic material. Perhaps a large number of practitioners will scarcely agree with the author when he says that narcotics, morphia, and chloral hydrate are of no use in eclampsia. As the convulsions cease in 85 per cent. of the cases after the birth of the child, he urges rapid delivery, especially in cases of deep coma and rapidly recurring attacks. Mechanical dilatation of the uterus, Dührssen's cervix-vaginal-perineal incisions are not for the general practitioner. Cæsarean section comes in only as an *ultimum refugium*. In some cases Cæsarean section in moribunda or mortua

may save a child's life. All operations should be performed under an anæsthetic, and he prefers chloroform to ether on account of the action of the latter on the salivary and bronchial glands. Suckling may be allowed as soon as circumstances permit. The hydropathic treatment is to be continued so long as the urine contains traces of albumen.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, September 2nd, 1899.

ATMOCAUSIS OR ZESTOCAUSIS.

At the *Versammlung Deutscher Naturforcher*, Guerard showed Pincus apparatus for the treatment of climacteric hæmorrhage by means of hot vapour at the boiling point.

Ever since Sneguirew declared to the profession that a high temperature was the best remedy for checking hæmorrhage, Pincus tells us that he has laboured assiduously to design an apparatus for practical use, which he considers is accomplished in the instrument exhibited.

The principle of the instrument is to conduct a stream of hot vapour into the uterus without scalding any of the outer parts of the channel, at the same time securing the safety of the operator against any personal injury from burning or scalding. With this instrument the boiling hot steam is confined to the interior mucous membrane of the uterus alone, he recommends it to be continued for ten seconds to half a minute, which will obviate many an operation for extirpation of the uterus due to intractable hæmorrhage during the climacteric period. In senile catarrh of the uterus two minutes will be required. He adduces many cases of obstinate hæmorrhage which have been relieved by this form of treatment ranged from 100 degs. Cent. to 115 degs. Cent. (212 degs. to 239 degs. Fahr.). Young persons are not able to bear this high temperature as long nor so easily as the old. He thinks better results can be obtained from a short application with a temperature of 105 degs. Cent. to 110 degs. Cent. than a longer period with a 100 degs. to 105 degs. Cent.

The reapplication should not be undertaken before regeneration of the mucous membrane takes place, which will probably be four weeks later.

The proper christening of this instrument has been a source of considerable difficulty to the patentee. At first the modest designation of vaporisers and vaporisation of the uterus sufficed to convey the author's meaning, but discovering that the effects were locally concentrated, and at a very high temperature, vapocauter and vapocauterisation was subsequently adopted as the more suitable expression. Later, the author turns it over again to atmocauter and atmocausis, and finally he discovers in his Greek lexicon that it should be Zestocauter and Zestocausis, from *ἡ ζεστότης*, seething or scalding. It may possibly be recognised by some of these names in future, but at present it is not decided.

The indications for this form of treatment are tabulated as endometritis, hæmorrhagic and gonorrhœic; endometritis puerperalis incipiens; atonia; climacteric hæmorrhage; senile catarrh; interstitial myoma; sub-involution; infarct sterilising cavity in putrid abortions; dysmenorrhœa, &c., &c.

Contra-indications are malignancy, tubal affections, abscess in adnexa, rigid portio vaginalis.

In the discussion Arndt thought the apparatus was especially suitable for climacteric hæmorrhage. He also added that the vapour flowing from the exhaust tube in the uterus was not 115 degs. Cent., as Pincus would have us believe, but only 65 degs. Cent.

Schlutius said that he had the apparatus modified to avert the danger of over pressure, and had obtained excellent results from its application in hæmorrhages.

MENSTRUATIO PRECOX.

Hofacker showed the meeting a singular case of a girl, æt. 9, who began to learn her letters when twenty months old. About the end of the first year she began to menstruate regularly every four weeks, each period lasting three to five days, before each of which she became languid and dull. She was as tall in her second year as a girl of seven years, but since that time this rapidity of growth has ceased, so that at the present time she is only at the normal height for her age.

The breasts are well developed; a rich crop of hair in the armpits and mons veneris. The labia minora and majora larger than normal; while the mental condition of the child seems to be retrograding.

In such precocities there is usually to be found some pathological change, and this is no exception to the rule, as rachitis has been diagnosed.

TREATMENT OF PUERPERAL FEVER BY INJECTIONS OF A COMMON SALT SOLUTION.

Eberhardt recorded great success with an injection of sodium chloride in cases of puerperal fever, and more particularly in those septic cases where vomiting is persistent and no fluids can be retained on the stomach, whereby the fluids of the body are reduced and poison more concentrated.

From the report of many experiments he showed that one litre of this 0.9 per cent. solution effectively produced diuresis, which promptly eliminated the bacteria with effete nitrogenous products. After this start the circulation of the kidneys became more vigorous, and averted all future danger of concentration in the kidneys. He was supported in this favourable report by Sahli, who could vouch for the beneficial effects of the solution.

He strongly recommended the treatment to practitioners, by whom it could be easily applied without any danger to the patient, which was also a serious consideration in these days of highly forced æsthetics.

Holland.

THE INTERNATIONAL GYNÆCOLOGICAL CONGRESS AT AMSTERDAM.

[FROM OUR SPECIAL CORRESPONDENT.]

(Continued from page 190.)

A CONGRESS may be said to serve two chief purposes, namely, the advancement of the science or the cause in which the Congressists are interested, and, secondly, a social purpose. It is conceivable that in earlier days, when a Congress was known as a Diet, the first object outweighed the other; the delegates met, discussed the questions of the day, and then returned to their own places without causing much stir. But this is not the way of doing things at the present time; the Congress is now raised into a kind of

FEAST OF LEARNING.

The delegates meet and discuss, it is true, but that is not the whole of the matter, indeed it is sometimes only the minor part. The gathering of men of name and fame from every part of the world into a town is the signal for entertainments, feasting, excursions, and hospitality of all kinds on the part of the authorities and of private individuals, who delight to do honour to those by whose presence they themselves feel honoured. This dual aspect must have impressed those who attended the Gynæcological Congress at Amsterdam.

THE SCIENTIFIC WORK DONE

cannot be regarded as insignificant; at a rough estimate I should say that about sixty papers were read, many of them being of considerable value; whilst, in addition, four important discussions were held, the total time occupied in solid work amounting to 24 hours. It is probable that as the result of these deliberations suffering humanity, and especially its female portion, will reap a material advantage in life prolonged and in health restored. It is impossible for me to criticise the papers and reports individually, but two papers call for a passing mention. With the aid of some excellent preparations, Mdle. Catherine van Tussckenbroek demonstrated beyond dispute the possibility of the occurrence of ovarian pregnancy. I believe that such a complete presentation of the case in favour of this condition has not hitherto been made. The second paper I wish to refer to is important from its probable results. It was one by Dr. La Torre, of Rome, on nomenclature of contracted pelvis, and it led to the nomination of an international commission of experts, who hope to report the conclusions at which they arrive to the Paris Congress next year. Yet the medical work done is probably not the aspect of the Congress which will leave the strongest personal impression on those who were present, because all that was read and spoken, is it not written in the book of the chronicles of the Congress, the *Comptes Rendus*, to wit? To this extent, the man who stayed at home will profit equally with the man who journeyed to Amsterdam.

OFFICIAL AND PRIVATE COURTESIES.

That which will remain more especially in the minds of those present is the memory of acquaintances formed and friendships matured with medical brethren who live far removed from our daily life, but whose names were deservedly familiar through their work. And perhaps more than all will be remembered the kindness and the hospitality shown, in public and in private, by State, municipality, and residents in and around Amsterdam. These things are not much dwelt upon in reports, and for this reason I wish to place them on record here. Moreover, I take it that the matter should be regarded, not simply as courtesy shown to a handful of our countrymen and their wives and daughters; but as an expression of goodwill towards members of the medical profession in Great Britain, in the person of their representatives. Professor Treub, president of the organising committee, and Dr. Mendes de Leon, general secretary, were quite indefatigable in their efforts to further the convenience and enjoyment of the visitors to the Congress; and I think many will recall their ubiquitous presence during the excursions to Scheveningen and to the Isle of Marken, where they seemed to feel a personal responsibility for every individual excursionist. In these efforts they were ably seconded by Dr. Stratz, Dr

Nijhoff, Dr. Van der Welde, Dr. Münlieff, Dr. Barnouw, and others. It would be as ungrateful as it would be ungallant to forget the part played in the festivities of the week by our two admirable hostesses, Madame Treub and Madame Mendes de Leon, who well exemplified the

DUTCH LADIES' STANDARD OF HOSPITALITY.

As is well known, this standard is high. Commencing with a charming reception at the Maison Couturier, these two ladies continued their gracious dispensations of hospitality throughout the week, in luncheon and dinner parties. Several of us also were from time to time the guests of Dr. and Madame Mendes de Leon at their delightful seaside villa at Landvoort.

I might write at some length on the various attractions which Holland offers to the visitor to its shores but that would be beyond my present purpose. I will only add that whether they go mainly for work or mainly for pleasure, visitors to this unique and fascinating country will not be disappointed.

The Operating Theatres.

ST. THOMAS'S HOSPITAL.

OPERATION FOR STRANGULATED VENTRAL HERNIA GANGRENOUS GUT.—EXCISION OF FOUR FEET OF INTESTINE.—Mr. BATTLE operated on a woman, æt. about 35 who had been admitted shortly before with a large ventral hernia and symptoms of acute strangulation. The stated that she had undergone some abdominal operation two years before, and that a scar had resulted below the umbilicus and in the middle line, and that it was not long before this scar began to bulge, and the present hernia was the result. The woman was vomiting frequently, the vomit consisting of a brown coloured fluid, not feculent. She was in a condition of serious shock, being pale-faced, restless, and with a small, rapid pulse. Her pain was extreme, and the hernia was very tender. There had been no action of the bowels, and she had passed no flatus. She stated that her severe symptoms had commenced during the previous night. Examination revealed a ventral hernia as large as the patient's head, which came through an opening in the middle line below the umbilicus. It was tympanitic on percussion, and very hard to the touch, whilst the surface, which had come in contact with the clothes, was superficially ulcerated. It was evident there was a condition of acute strangulation. An operation was performed as soon as possible. The surface of the hernia and the surrounding skin were thoroughly cleansed, and the pubes shaved; the sac was then opened to the left of the middle line and a coil of gangrenous intestine found, there was also a very offensive purulent fluid in the sac; the first coil of intestine occupied a kind of diverticulum of the main sac, and it was hoped that this was the limit of the gangrenous process, but as the incision was extended it was found that there were several of these loculi, and that the whole of the intestine which occupied the large sac was in a condition of gangrene. There was no omentum in the sac. The patient's general condition was now very bad, and the question as to duration of operation was very important it was evident that she could not stand excision of the gangrenous part which was estimated as more than

three feet in extent, and included the cæcum part of the ascending colon, the appendix, and some ileum, and it was not thought prudent to attempt resection alone on account of the increased shock which would have undoubtedly followed. It was decided therefore, to close the abdominal opening, leaving the intestine affected outside. A tube was placed in the ileum where it appeared healthy, and then the gangrenous gut was emptied of its contents, thoroughly washed with perchloride of mercury, dusted with iodoform, and then closed with a layer of cyanide gauze. The patient rallied satisfactorily from this operation, and two days afterwards the gangrenous intestine was excised. The number of vessels requiring ligature showed how unwise it would have been to have attempted this at the first operation. A Paul's tube was fastened into the end of the ileum, and another into the end of the ascending colon, and the whole wound thoroughly disinfected. The portion of intestine removed measured more than four feet. Mr. Battle remarked that he hoped to re-establish the intestinal canal on some future occasion when the patient had sufficiently recovered. The case, he said, was a very unusual one, because the opening through which the hernia had come was large enough to admit four fingers, and it is not common to get such acute strangulation when the opening is of such large size. This was certainly a most acute process, and perhaps the absence of omentum in the sac was partly accountable for it. The gangrene of the large intestine ceased abruptly at the point where the edge of the opening had compressed it.

ST. MARK'S HOSPITAL FOR FISTULA.

CARCINOMA OF THE RECTUM COMPLICATED WITH A PERIRECTAL TUMOUR.—Mr. SWINFORD EDWARDS operated on a man, æt. about 55, for malignant disease, which extended up the bowel for about three inches. The patient had only complained of symptoms for six months; he was singularly free from pain, but suffered at times from a sanious discharge from the rectum, accompanied by frequent desire to stool. Ether having been administered, the patient was placed in the left lateral decubitus, and Mr. Edwards inserted his finger into the rectum in order to make a more thorough examination than he had previously been able to do; immediately above the growth the finger touched a rounded elastic swelling over which the mucous membrane was freely movable; this tumour lay towards the front of the rectum, apparently between it and the bladder. In order to make a more thorough examination a posterior proctotomy was performed; the swelling now appeared to be the size of a tangerine orange. Although somewhat movable, it seemed to have deep attachments to the pelvis. Under these circumstances it became a question whether it was worth while attempting to remove the carcinoma, as the tumour first referred to might possibly be either glanular enlargement or extension of the disease upwards, not involving the mucous membrane. However, having exposed the diseased area, Mr. Edwards thought it best to proceed to remove the portion of the rectum which was evidently carcinomatous before proceeding to deal with the other tumour. The patient having been placed in the kneeling posture, a modification of Godlee's position recommended by Littlewood (the patient being placed as for dissection of the buttocks, the chest and abdomen being on the ope-

rating table with the pelvis raised (and the knees flexed and resting on a chair to which they are attached), the lower portion of the rectum, including the anus, was removed from below upwards, the part of the gut just below the tumour being clamped with large pressure forceps. About three inches of bowel were removed in all, and the peritoneal cavity escaped injury. As the patient was now in a somewhat collapsed condition, it was not thought advisable to proceed with the removal of the extra-rectal tumour, but to leave this for observation and possible further operation. It was found difficult to apply ligatures to some of the deeper vessels, so pressure forceps were left on and the wound packed with gauze. Mr. Edwards said that this was an unique case in his experience, for it was rare to have a case of carcinoma of the rectum complicated with what appeared to be a perfectly distinct tumour, the features of which pointed rather to an innocent than to a malignant growth. From its feel he thought it might not unlikely prove to be a dermoid, as it was quite smooth, somewhat movable, and elastic. As he had before remarked, the mucous membrane was freely movable over it, as also probably the muscular coat. It was a matter for regret, he thought, that the patient's condition did not warrant further operative interference such as would be necessary for its removal. With regard to the patient's position he had employed this posture because at first he considered he might have to perform a Kraske's or similar operation. Mr. Edwards thought this modification of Godlee's position recommended by Littlewood, to be the best when Kraske's operation was undertaken, but for a case such as the present one in which a more limited operation had sufficed, no bone having been removed, and the peritoneal cavity being left intact, he considered a better view would have been obtained in the lithotomy position; he pointed out, however, that even with the many advantages of Littlewood's position it had one great drawback, that it was very difficult to keep blankets on the thighs and to protect them from getting soiled, as mackintosh sheeting was very apt to slip down.

It is satisfactory to say that the patient a fortnight after operation is doing well. The hæmostatic forceps were removed after forty-eight hours, the large wound is granulating nicely, and the peri-rectal tumour shows no sign of increase.

ACQUIRED SYPHILIS IN AN INFANT.

ACQUIRED syphilis in an infant of seven months is a recognised rarity. An interesting case of the kind is recorded in the current number of the *New York Medical News*, by Dr. L. D. Bulkley. The primary lesion was a chancre on the lower lip, which was apparently traced to the infected nipple of a feeding bottle. Upon the trunk was a fully developed macular syphilide, which had been noticed for four days. The child was well nourished and of splendid development. The mother was healthy. The chancre was half an inch in diameter, there was enlargement of the glands under the jaw. The infant having been fed by the bottle, the supposition was that the infection was conveyed by some one who had tasted the contents of the bottle to ascertain if the food was of the proper temperature.

WEDNESDAY, SEPTEMBER 6, 1899.

PROVISION FOR THE MENTALLY DEFICIENT.

No excuse is needed for referring once again to the Poor-law provision for the mentally deficient class, for although there has been much talk very little has been really done. The question is a very large one, and to reduce the whole matter to practice instead of theory would imply a considerable unanimity of opinion on the part of Public Boards in England. When we consider the various classes of the feeble-minded, the different accommodation required for them, and the need of specialised treatment for those who are capable of some educational or industrial training, it will be seen that a very important revolution of affairs is involved in reducing suggestions to a practical form. No one will question the axiom that lunatic asylums are not the most suitable places for juvenile imbeciles even for those requiring custodial care, but when we consider the immense charge that lunacy has been to this country, and the extravagant ideas which now prevail regarding the building and equipment of modern asylums, we are not surprised that there should be hesitation and delay in differentiating, in the manner proposed by Dr. Shuttleworth in his address before the recent Poor-law Conference. That his requirements are good goes without saying, but there are practical difficulties in the way which cannot readily be got over. Thus, for example, we find that the statistics of this class are insufficient to form a basis for structural erections or changes because of the large number of imbeciles who are not treated in institutions of any kind, but are allowed to roam about at their own sweet will, and are wholly

or partly provided for by doles from Boards of Guardians. As a very good example of what is being done and what ought to be done, Dr. Shuttleworth quotes the combination of the great Unions of Manchester and Chorlton, which on the instigation of Dr. J. M. Rhodes, who has devoted much intelligent attention to the treatment of imbeciles, combined to establish a colony for 1,500 epileptics and imbeciles now accommodated in their workhouses. A site has been secured, and if this be approved by the Local Government Board, cottages will be erected on the Alt-Scherbity plan to accommodate groups of fifty patients, with central administrative offices, infirmary, &c. A similar combination of Unions to establish a school for pauper imbecile children has been suggested by the Birmingham Guardians, but so far without success. Of course there are voluntary institutions, such as those at Earlswood, Lancaster, Colchester, Starcross, and Knowle, affording in the aggregate accommodation to 1,700 patients, but those do not meet all requirements and do not profess to admit paupers. It is pointed out by Dr. Shuttleworth that where there is no such charitable provision, or a totally inadequate one, as in the Midland Counties, the urgency for the provision of imbeciles is greatest. Voluntary homes have been established in various parts of the country by charitable effort, the weekly rates of payment varying from 5s. to 7s. A confederation of existing homes, which are usually for twenty inmates, has been formed, and full particulars may be had from the National Society for Promoting the Welfare of the Feeble-Minded, 53 Victoria Street, S.W. We have taken special notice of Dr. Shuttleworth's paper because he is an acknowledged authority on the subject, and because we feel strongly with him. Those interested and anxious to see an improvement in the present system, should (as he describes it) "keep pegging away." It is earnestly to be desired that something may be done, for it is sad to think of the neglected opportunities that have been at our door for years, and of the young lives that might be brightened and improved, morally and socially, as well as intellectually by well-directed efforts on their behalf.

THE PHYSICS OF AUSCULTATION.

ONE of the most important improvements in the diagnosis of diseases was that which was effected by the work of Laennec, when he turned attention to the methods by which the sense of hearing could be utilised in a manner not previously observed or appreciated. The eye and the hand, the sense of sight and the sense of touch, were the two senses we chiefly relied upon in medical and surgical practice. How to use the ear did not seem to have occurred to others as it did to Laennec. What could be learnt from the use of the ear in the diseases of the most important organs of the human body, the heart and the lungs, was first pointed out by him; and there is no subject which attracted so much attention in the profession about half a century ago as the use of the stethoscope.

As far as this instrument is of use it is quite clear that its value depends on the assistance it affords in the conduction of various sounds from the patient's body to the ear of the physician. The question of how and why various changes in the heart and lungs can cause various sounds is quite different from the question how we can best hear them. The only way to obtain answers to the first question was clearly dependent more on pathology or morbid anatomy than upon anything else, though experiments on living animals were to some extent resorted to. On what principle the stethoscope should be constructed, and how the instrument could be best applied to the detection of variations of sound in the heart and lungs, is a subject that can only properly be dealt with by those who have studied the science of sound, by such men as the late Prof. Tyndall, who gave special attention to it. When we see that it was Tyndall who presented to the Royal Society the paper which Dr. Alison wrote on the stethoscope, we have evidence that he saw the importance of using the science of sound in medical practice. There seems, however, to have been a want of scientific knowledge on the part of Laennec and his followers in his own and other countries. Various names were invented to describe the various sounds which could be heard in the heart and lungs when certain pathological changes occurred in them. Souffles, bronchophony, ægophony, pectoriloquy, murmurs, frictions, and various others were used to describe certain well-known affections of the tissues of the heart, pericardium, lungs, and pleural cavities. And then the method of percussion became of importance, and how best to use it was attractive to many physicians. To go back, however, to the physics of auscultation, we have to consider on what scientific principles we depend when we try to use the ear in diagnosis. In the case of the lungs we are dealing with vibrations of air; in the case of the heart and blood vessels with vibrations of a fluid—and how best to carry these through an instrument to the ear requires some consideration. Would the same conducting medium answer equally well for both is a question we need not discuss. A point, however, that we consider still requires study is the qualities of the vibrations of air and fluid, or, rather, the differences between them; and then we shall arrive at some conclusions how best to convey them to the ear. The curious way in which a thin layer of fluid in the pleural cavity alters the voice sounds, and the difference between a solid stethoscope and a tubular one in heart and lung diagnosis, we know depends on the variation in the conduction powers of solids, liquids, and air. There seems to have been more ignorance than we should have expected in a great deal that has been done in this line of medical research. The reason, we suppose, is because the science of the physics of sound was not sufficiently well known in the profession to prevent the imagination from misleading, and much time and trouble being wasted to no purpose.

INTERNATIONAL MEDICAL CONGRESSES.

Now that the novelty of the huge gatherings which pass muster for international scientific congresses is passing off, the intelligent public are beginning to ask themselves whether these modern Babels really do much for the advancement of science, and of medical science in particular. Experience shows clearly enough that the contributions, which are bewildering in their abundance, rarely convey original information, or, indeed, any information that has not already been, or would not subsequently be, published to the world at large through the medium of the press, under conditions far more favourable to judicious elimination and emendation than the editors of the portly volumes of proceedings can possibly secure. As a matter of fact, the reading of papers at these congresses is more or less a farce, seeing that in such a Babel of tongues anything in the nature of a thorough discussion is impossible, partly for want of time, partly by reason of the multiplicity of languages. Judging from the prominence invariably accorded to a particular series of names, the principal object of these meetings appears to be that of affording certain energetic persons the longed-for opportunity of blowing their respective trumpets to the best advantage. It may be urged, on the other hand, that the gathering together of scientific men from all parts of the world must tend to obliterate insularity and to pave the way to personal acquaintanceship between investigators who are following the same lines of research. So far, so good, and we are not concerned to deny that advantages of this kind may, and do, result from the opportunities which international congresses afford. The recent Obstetrical Congress at Amsterdam shows, however, that, instead of obliterating international jealousies, these meetings afford an unrivalled opportunity for placing them *en evidence*. For many years past the German-speaking countries of the continent have been the happy hunting ground of German professors, an invasion which, naturally enough, has awakened native susceptibilities. This feeling has reached a crisis in Holland where a stand has been made against the encroachments of German professors with the result that at the recent Obstetrical Congress the German delegates ostentatiously abstained from assisting thereat, although they had accepted the posts assigned to them and their papers had been printed. A similar movement is pretty certain to take form in Switzerland where German professors have, in many instances, succeeded in ousting the Swiss candidates for professorships. The movement is likely to spread, and may ultimately prove fatal to the future of the international congress as at present organised. The vice of the present method is in particular the utter absence of selection, and this vice attains its maximum in congresses not devoted to a specialty. There is an abominable plethora of papers emanating from men who for the most part are unknown to fame, even to that restricted fame which is limited to their own frontiers, and there is in reality no attempt to edit the pro-

ceedings. The consequence is that the occasional grains of wheat are submerged in an incredible quantity of stuff which is neither original nor interesting. In fine, there is no scientific object which cannot be attained by the publication of contributions in the columns of the medical and scientific press which, after all, is the path by which the carefully sifted proceedings ultimately reach the profession. The criticisms which we have passed on international congresses apply *mutatis mutandis* to national congresses except when these meet for the discussion of a specific subject, such, for example, as tuberculosis.

Notes on Current Topics.

The Plague in Europe.

DR. MENDOZA, one of the two Spanish physicians sent from Madrid to report to the Government on the outbreak of the plague in Oporto, writes to our Spanish contemporary *El Siglo Medico*, on the subject, that the first cases of plague in the city occurred among quay labourers who were employed discharging the steamship *City of Cork*, of a cargo which she shipped in Bombay. The cargo was reported to consist of hides, the importation of which is prohibited in Portugal, but this is denied, and the cargo is declared by the agent of the shipping company to have been bags of rice and chests of tea. And it is urged that the customs authorities would not allow of the discharge of a cargo of hides. Dr. Mendoza, nevertheless, thinks that it is quite possible that the cargo was of hides although he quotes the case of the introduction of the plague germs into Madagascar in a cargo of rice as showing that the germs may have been brought with the rice. The outbreak took place on June 22nd, the day the steamer was unladen; it assumed the fulminant type in the case of the labourers who were engaged on the *City of Cork* and a less virulent type among those to whom they transmitted the disease. In their report to the Government Drs. Vicente and Mendoza, state that the cases examined had all the well-known characteristic symptoms of the Eastern plague. They carefully examined diseases, three of men and of women, which were under the care of Dr. Noguerias, in Misericordia Hospital. Four of the cases, one man and three women, had enlargement of the glands of the inguinal, axillary, submaxillary, and cervical regions. The three women were suffering from pneumonia. In one fulminant case the inguinal glands suppurated and bled, and a rash resembling chicken pox appeared, petechiæ appeared on the chest, the skin became cyanotic, and death resulted in twenty hours. Writing on August 16th, the physicians conclude that the epidemic is arrested, and that its virulence is greatly diminished. No antitoxins were used in the treatment, for the very good reason that none were to hand, there was not sufficient time for their preparation. The Spanish Government has placed a sanitary cordon round the Portuguese territory, bordering

Spain, under the charge of General Mariano Capdepon, and at Valencia de Alcantara, Fuentes de Onoro, and Fregenada, Juy, and Padajoz. a doctor with a military guard is stationed to prevent infected persons or goods crossing the border. Any person coming from any suspected centre of infection is to be detained for such time as the medical officer in charge thinks necessary up to ten days, which is considered by the authorities as the maximum period of incubation. Arrangements are made for the disinfection of the person, clothing, and luggage or wares of the traveller, and none are to be allowed to pass without being submitted to the process. A royal order further charges all medical men to notify to the central authorities any case occurring in their practice resembling plague, and to inculcate on the people the necessity for keeping their dwellings clean. Dr. Ovilo has been entrusted with the carrying out of the sanitary arrangements. Twenty tent hospitals, in groups of five, are provided. Of these ten are set apart as observation tents, and of the remaining ten five are reserved for men and five for women. With these are installed apparatus for cooking, lighting, sanitation, disinfection, and an abundant water supply. Senor Dato, the member of the Government charged with the direction of sanitation, has expressed his gratification at the completeness of the arrangements made in this epidemic hospital for fighting the plague.

What Constitutes Pecuniary Ineligibility for Hospital Relief.

A GREAT misconception undeniably prevails in the minds of most laymen relative to consultants' fees, and this fact is made very prominent by a letter published in the *Times* last week on "Hospitals and Out-Patients," by Sir Trevor Lawrence. He raises the question of what should constitute pecuniary ineligibility for hospital relief, and adduces the case of a clerk, whose income may be £200 per annum. Such a person he maintains would be quite unable to pay fifty or one hundred guineas for an operation, with all its attendant expenses, and, therefore, those who belong to the class of clerks, he considers are not ineligible for hospital relief. We are sorry to see that Sir Trevor should have fallen into the error of supposing that a hard and fast line exists by which it is impossible for consultants to accept reduced fees. As a matter of fact it is the rule rather than the exception for modified fees to be offered and taken. Indeed, if this were not so, the surgical beds of our hospitals would soon be crowded by persons able and willing to accept those modified terms. Moreover, it is quite a mistake to suppose that there are no nursing homes whose proprietors do not cater for the class of persons in question. Most operating surgeons are acquainted with surgical homes where the weekly charge is only two guineas. We are, therefore, bound to disagree seriously with Sir Trevor Lawrence when he contends that a clerk earning £200 a year is not in a position to pay the fees of a consultant for a grave operation. There are many young hospital

surgeons who cannot expect to obtain full fees for their operations, and it is to them that clerks and others similarly placed in a pecuniary sense should apply. Perhaps some of the junior members of the staff at St. Bartholomew's Hospital, of which institution Sir Trevor Lawrence is the treasurer, will take steps to point out that they are quite prepared to operate upon any number of £200 per annum clerks at reduced fees. The truth is that it is only a very select few of operating surgeons whose independence is such as to enable them to claim the maximum fees for their operations.

Opium Eating.

AN inquest held last week in London upon the wife of a dock labourer, called attention to a form of drug craving of which one rarely hears nowadays. From the evidence it appeared that for no less than thirteen years, according to her own statement, deceased had been in the habit of taking opium. The husband stated that his wife met with an accident eighteen years ago, and ever since had been in the habit of taking opium pills. She bought about three pennyworth of the pills every day, and procured them from a chemist in the East India Road. The medical testimony pointed to the drug mentioned having been the indirect cause of death. The coroner drew attention to the fact that the box in which the pills were sold was not labelled, although the opium was a scheduled poison, and there was no actual proof as to where it was purchased. The infraction of the law, as laid down by the Poisons Act, appears to be clear enough, and if that salutary law is not to become a dead letter, the present is evidently a case in which the police should prosecute. So far as we can judge from the evidence of coroners' courts, there is no law more systematically evaded than that which is framed to regulate the sale of poisons. Why should this be? Even the national interest in the affairs of South Africa can hardly excuse a social omission of this kind. So far as the opium habit is concerned, there is reason to believe that the practice is widely prevalent in various parts of the United Kingdom, more especially in rural districts. From the facts of the case, however, this form of indulgence seldom comes to light.

The Weighing of Packet Wrappers.

FOR some time past the community has been witnessing a series of duels between various local authorities and dealers in tea, upon the vexed point as to whether the vendor should be permitted to weigh the wrapper along with the amount sold to the customer. Clearly, if the practice be allowed, the grocer is selling cheap paper at the price of tea, and in large transactions must come out considerably the gainer. Indeed, this point has always been evidently one in which the poorer classes have to pay a higher proportionate price for their commodities than the rich. Four quarter pounds of tea mean the purchase of four paper wrappers, whereas the rich man gets his full value by buying in bulk, say, a seven pounds'

parcel of tea weighed independently of the tin canister in which it is delivered. A similar sharp practice applies to many articles other than groceries. The chemist, for example, vends many drugs in which the gross weight includes the wrapper. Nor are the tobacconist and the buttermilkman above suspicion in the matter. Many worthy folk want to know why the local authorities should attack the jam-makers upon a disputed point as to the use of absolutely fresh fruit in their trade, while the vast army of offenders in the shape of milkmen, grocers, chemists, buttermen, and other purveyors of food are allowed to go practically scot free. The key probably lies in the constitution of the vestries. How many adulteration prosecutions take place annually in each London parish on an average? Yet gross adulteration is rampant. It is easy to attack the large merchants and factory owners, who are regarded as fair game by the small tradesmen who virtually rule the vestries.

Lockjaw in Kent.

FOUR deaths from tetanus have been reported within the last ten days from Kent. In two at least of these cases there was presumptive evidence of soil contamination, namely, those of a cyclist and of a quoit player who met with accidents. Traumatism was present in each instance. The infectivity of soil in these cases is now well established, and the only wonder is that tetanus is not a much commoner affection, when we take into consideration the vast number of wounds, both serious and trifling, that are exposed to soil contamination. The progress of our knowledge with regard to this most terrible of human maladies reads like a fairy tale of science. It is only a few years ago that medical men were absolutely in the dark as to the origin of tetanus, although the share of soil in causation had long been recognised. In 1889 Kitasato succeeded in isolating the specific organism, which, with its "drumstick" shape and its numerous flagella, forms an attractive object under the microscope. The next great step in advance was the work of Faber, who showed that the symptoms of the disease could be produced by the injection into susceptible animals, as mice and guinea-pigs, of culture fluids freed from the specific bacillus. The history of the tetanus experiments and researches is well worthy of careful perusal by the medical practitioner who has not the opportunity of working at practical bacteriology.

The Registrar-General and Death Certificates.

A WEEK ago the subject of death certificates was dealt with in a leading article in the *MEDICAL PRESS AND CIRCULAR*. In the course of our remarks we felt it a duty to reflect strongly upon the way in which the Registrar-General played into the hands of unlicensed practice by allowing his local representatives to receive lax and informal notices of death from various quarters. This week the truth of some of our claims has been virtually admitted by the issuing of an order from the Registrar-General to District Regis-

trars not to accept certificates of death unless deceased had been attended by a doctor within a period of three days prior to death. This is a step in the right direction, and it is to be hoped that the Registrar-General will follow up his new policy of attempting to render death certification something less of a farce than it is at present. The right thing would be to allow no corpse to be buried unless properly certified by a qualified medical man or by a coroner after due inquiry. Otherwise the due protection of life, so far as it can be checked by official machinery, is at an end. Medical men have done foolishly in not refusing a certificate when they have not attended within a few days of death, but the registrars will now discharge the unpleasant duty of negation for them. By the way, this new order will knock on the head the laxity of the hospital physicians and surgeons who have so cheerily granted certificates of death in cases they have seen perhaps once some time before death.

The Dangers of Prolonged Sea Bathing.

SEVERAL instances of illness due to excessive bathing in the sea have come under our notice. In each case the patient suffered from pains in the limbs, depressed circulation and prostration, with general symptoms of malaise and "chill." The duration of the illness was in some instances three weeks or more, showing that the nerve centres had received a severe shock. Enquiry proved that on several successive days the sufferers had remained in the sea for at least an hour under a scorching sun. The unwisdom of such a proceeding in persons who are not accustomed to prolonged baths and to violent muscular exercise is all too apparent. A young man fresh from college training can swim for an hour with ease and afterwards be none the worse for it. But how wide the difference between experience and that of a woman who perhaps takes a morning sponge bath and little or no active exercise! Can she be expected to face the extremes of temperature involved in an hour's sea-bathing, to say nothing of the sheer hard muscular exertion of paddling, floating, swimming, and moving about in a tidal water? The proper length of a sea bath for a novice should not be more than five or ten minutes, gradually lengthened as tolerance is acquired. Even a man who has been a strong swimmer needs to begin sea-bathing cautiously after a long abstention. Many a whilom athlete has met his death by trusting to his former prowess. Yet sea-bathing, properly used, is undoubtedly a most valuable means of restoring health and tone to the debilitated.

Lead in Condensed Water.

IN a recent issue of the *Australasian Medical Gazette* Mr. R. R. Harvey, M.B., Medical Officer of Health for a West Australian district, points out a danger connected with the use of condensed water. In the gold districts of the region in question there is great scarcity of water, and the drinking supply has to be obtained by condensation of the salt water obtained from shallow wells. Under certain conditions the heat is apt to release muriatic and sul-

phuric acids from the salt caked on the sides of the boiler, and the acids then eat away the lead of the solder and form various poisonous metallic salts. A peculiar form of anæmia is prevalent on the gold fields, and it is believed by the people to be due to the want of fresh vegetables and to the use of tinned foods. Mr. Harvey has met with several cases of chronic lead poisoning, and not unreasonably concludes that much of the anæmia may be attributable to the same cause. His practical conclusion is that the condensing of water should be conducted under skilled supervision. In Great Britain the risk of plumbism from that source is not likely to occur. Still the medical man will do well to bear in mind the possibility of such an event. Now that many ocean steamers are in the habit of using condensed water it would be interesting to learn whether any cases of lead poisoning have ever been traced to that quarter. It might be suggested to the Western Australian authorities that they should prohibit the use of lead in all condensing apparatus, a condition that would not be very difficult to satisfy.

Sewer Ventilators.

ANYONE who has taken the trouble to notice the sewer ventilators in the London streets must have been astonished to find that the majority of them are merely ventilators in name. It is quite the exception to come across a ventilator which is not firmly blocked up with road refuse. So far as the City is concerned we glean the explanation of this from a letter which appeared in the *Times* last week from the City Medical Officer of Health. This official asserts that his sanitary committee take every opportunity of closing openings in roadways from subsidiary sewers, and ventilate the same by shafts of six inches in diameter affixed to the nearest building. He also adds that two hundred and eleven of these shafts have already been erected in the various districts. We are disposed to take exception to this arrangement. The principle is undoubtedly sound, but its application is faulty. There should be just as many ventilating shafts as there are road ventilators; unless this be the case, there is bound to be a high pressure of sewer gas at the higher levels. Should it then so happen that a road ventilator be open at this part, it is not difficult to understand that the opening would give exit to volumes of gas, and thus cause a nuisance. Failing, however, a multiplication of ventilating shafts, such as appear to be in use in the City, we think that plenty of road ventilators carefully kept in a patent condition is the next best plan of sewer ventilation. By this means the gas by having many channels by which to escape has no opportunity of reaching the outside air in a state of high pressure. The nuisance under these circumstances is not directly the sewer opening in the roadway, but the faulty ventilation of the sewer by which the gas contained therein has been allowed to accumulate and escape in bulk. If the sanitary authorities throughout the metropolis were to see that every road ventilator was kept free and open we

have no hesitation in saying that the complaint against special openings of the kind would soon cease. Meanwhile the attention of the London County Council might well be directed to this matter.

Boracic Milk.

THE Board of Agriculture have been appealed to in order to prohibit the sale of "milk extract," which consists of condensed milk, without sugar, preserved by boracic acid. Apparently during the summer considerable quantities of this preparation have been sold at seaside resorts and other places where the demand for milk has surpassed the natural supply. It is said to be prepared in Lombardy, and an analyst attached to the Inland Revenue has reported that the amount of boracic acid in the milk was not of sufficient quantity to substantiate a charge of adulteration against the vendors. Under the circumstances, then, the Board of Agriculture have intimated that they can do nothing in the matter. This is rather a serious state of affairs. Is it to be henceforth understood that milk can be mixed with a certain proportion of boracic acid and still, from a legal point of view, be an unadulterated product? What constitutes adulteration in such a case? The answer to this question is one which the authorities concerned should lose no time in considering. The position seems to have been assumed that adulteration cannot be proved unless the boracic acid in the milk is in sufficient quantity to cause harm to the consumer. That is to say, the acid is placed upon the same footing as the sugar, the latter being the ordinary preservative used in condensed milk. Clearly in the interests of the community generally some authoritative conclusion should be arrived at in regard to the use of boracic acid as a preservative of food.

Boards of Guardians and the Appointment of Vaccination Officers.

THE law officers of the Crown have just burst a bombshell in the anti-vaccination camp. The Lutterworth Board of Guardians recently appointed a vaccination officer with a condition attached that he would only institute proceedings against defaulters under the Vaccination Acts when specially authorised by the guardians under their common seal. This arrangement naturally did not meet with the concurrence of the Local Government Board, and the latter authority felt it their duty to remonstrate. Subsequently the matter was referred to the law officers of the Crown, who reported that the duties of the vaccination officer were defined by the Acts relating thereto, and could not be curtailed, restricted, or superseded by any resolution of Boards of Guardians. Consequently, the appointment made by the Lutterworth Board was declared to be void, and thus the guardians have been called upon to make another which shall be in accordance with the Acts. We are glad to see that the Local Government Board are showing their determination not to be trifled with in regard to the administration of the Vaccination Acts. If the Board were to display any laxity in

their dealings with the guardians in this matter vaccination would soon degenerate into a farce, and no one could predict what the ending thereof would be.

Successful Removal of Sarcoma of Brain.

THERE is no branch of regional surgery that has made greater strides within the experience of the present generation than that which deals with the brain. Like all other organs situated in cavities the brain has been brought within the range of practical surgical therapeutics simply and solely by the introduction of Lister's system of aseptic surgery. In view of what has already been accomplished it may safely be asserted that the limit of brain surgery still lies hidden away on a remote horizon. The recent introduction of the practice of trephining and injecting curative serums into the substance of the brain opens up a new and suggestive field of direct therapy of organs. Clearly it would be quicker to inject such a serum into an affected gland than to allow it to reach the desired spot indirectly and in a diluted form by means of the general circulation. Of all brain conditions, however, that of sarcoma would appear to be least amenable to the surgeon. A successful case of the kind, nevertheless, has been reported by Carle in the *Revue de Chirurgie*. He removed a sarcoma from the left frontal lobe of a patient who showed localising signs. Two years later the patient remained well, and was intellectually clear, the only remaining trouble being a slowness of speech. This case is worth careful consideration by all who are interested in brain surgery.

Chemists Beware!

THE relations between the dispensing chemist and the medical profession are not altogether of the most harmonious nature, and it is to be hoped that one day the legislature will put a stop to the pernicious custom of counter-prescribing. The most heated opponent of this form of unqualified practice, however, will hardly approve of the latest rigours of supervision to which the tradesmen in question have been subjected. At Fulham, several chemists were last week prosecuted by the Vestry for "selling a compounded drug not composed of ingredients in accordance with the demand of their purchaser." At first blush the reader will conclude that the object of the prosecution was a fit and proper one, but he will most likely alter his opinion on hearing further details. It appears that a prescription was made up by the defendant, and according to the vestry's analyst the bottle contained 258 grains of iodide of potassium, instead of 240, as ordered. The magistrate dismissed the summons as he thought the Act was meant to deal with frauds, and had no relation to a trifling excess of an ingredient in a bottle of medicine. The futility of such a prosecution lies on the surface. If this hair-splitting Vestry, instead of attacking a chemist on such shadowy and debateable ground, had taken a dozen samples of simple everyday drugs and had tested their purity, then a solid service would have been rendered to the public. The laxity, or rather

the absence, of anything like a systematic control over the purity of drugs vended to the community is nothing short of a scandal. Yet all the needful machinery lies at the elbows of the vestries.

Gainsborough as a Plague Spot.

IN 1894 the Local Government Board made an official inquiry into the sanitary condition of Gainsborough, with results that furnished a most unfavourable commentary upon local administration. Hence, in the absence of detailed and definite information as to certain deaths registered as due to "fever" another inquiry has been conducted by Dr. Muir, Medical Inspector of the Board. His report discloses a scandalous condition of affairs, so much so as to be hardly credible. A large number of the houses have middens, which are badly made and neglected. The sewers are unventilated and for a great portion of the day tide-locked, the drains often untrapped, and the general disposition of the sewage disposal apparently such as to secure the greatest possible amount of soil contamination. The sanitary inspector is a retired cabinet-maker, sixty years of age, who seems to content himself with an intermittent supervision of the scavengers. Nuisances abound throughout the district, and typhoid-infected middens are left untouched in spite of frequent applications for cleansing on the part of owners. The inhabitants of the place are for the most part drawn from the working class, and numbers of their dwellings are "so damp and dilapidated from age or neglect as to be unfit for human habitation." Gainsborough, in short, is in a state that may well make the sanitarian pause when he is inclined to boast of the progress made by Great Britain in practical preventive administration. If this backward urban district will not do its duty, then Government must interfere. Would it not be possible to prosecute the Council for polluting the Trent, into which they discharge large quantities of raw sewage? Surely the Pollution of Rivers' Act may be made a lever for exerting indirect pressure upon the rulers of unwholesome Gainsborough.

The Assuan Hospital.

MESSES. JOHN AIRD & Co. have sent us a copy of the First Annual Report of the Assuan Hospital established in connection with the Nile Reservoir Works. It is of interest to note that the staff consists of Dr. E. Schmitt, as chief medical officer, Dr. Fahri, an assistant medical officer, Dr. Montessori, an Italian, especially engaged to attend to the large contingent of Italian labourers; three trained male nurses and a female housekeeper, apparently the only woman upon the premises. There were a total of 198 cases treated during the course of the year, 28 of which were fatal. The accident cases numbered 53, 10 of which were fatal. The total number of beds is 48, and these include separate quarters for the Europeans and natives. The remarks in the report upon the cases of sunstroke and heat affections, numbering 33, are especially noteworthy. It is stated that in

almost every serious case the patient was found to have drunk to excess, whisky and beer being the source of harm with Englishmen, and mastic with other workmen, and it is further added that, provided that a man is temperate and takes proper precautions, there is very little risk of sunstroke. Perhaps the firm might take up the question of encouraging temperance among their workpeople by providing non-alcoholic beverages at a cheap rate.

Yellow Fever in Virginia.

THE following account of the present epidemic of yellow fever in the State of Virginia (*Vir. Med. Semi-Monthly*) will do much to allay the fear of a serious outbreak of the disease among our American cousins: "It seems probable that the thirty odd cases of yellow fever announced July 30th in the Soldiers' Home at Hampton, Va., formed a part of an endemic that had existed for a week or more. As best can be learned, the disease was introduced by an 'Old Soldier' who spent some days of his furlough in June and early July in or about Santiago. The usual error of diagnosis of dengue was first made of cases in the hospital prior to July 30th, when the Virginia State Board of Health, the military authorities at Fortress Monroe, and the health officers of the towns and counties near by were advised of the true nature of the disease. At once quarantine was declared against infected sections of the peninsula of Virginia, and the disease has shown no tendency to spread—up to this date (August 7th). Beside the prompt, rigid measures of quarantine adopted at once by Newport News, Norfolk, Portsmouth, &c., the Virginia State Board of Health, as far as its limited means will allow, aided by a donation from the contingent fund under the direction of the Governor of Virginia, has commissioned medical inspectors along all the lines of travel coming from the infected section on York River, James River, Chesapeake and Ohio Railroad, Norfolk and Western Railroad, &c. It seems to be the opinion of experts and those in authority that the apprehension of an epidemic is at an end. This is the first time yellow fever has originated or caused any alarm in Virginia since the terribly severe epidemic of 1855—forty-four years ago."

MESSRS. BURROUGHS AND WELLCOME were awarded a silver medal for the solid disinfectant at the Health Exhibition recently held in Southampton.

THE CONGRESS OF THE SANITARY INSTITUTE.

THE past week has been marked in the medical calendar by the assembly of the Sanitary Institute in Southampton—brought to a termination on Saturday, the 2nd inst. The gathering was larger than had been expected, so much so that, even for many of those who had sought to reserve hotel accommodation several days beforehand, much difficulty was experienced in getting even good lodgings. Nearly 500 names appeared on the official list of members present, while, probably, as many more camp followers (if we may use the phrase) accompanied them. The Mayor, in one of his addresses,

estimated the total number of those who took part in the proceedings in one or other form at 1,750. The municipality offered its hospitality through the medium of the worshipful the Mayor (Councillor Hussey), the Senior Bailiff, the local hon. secs., Dr. Wellesley Harris, Medical Officer of Health; Mr. Matthews, C.E.; Mr. Bennett, C.E., and Dr. Russell.

The Institute itself was represented by Sir William Preece, K.C.B., the newly elected president; Mr. Law, chairman of the Council; Sir Henry Littlejohn, by several other leading members of the Council, and by Mr. White Wallis, P.S.S., its very efficient secretary.

After the initiatory ceremonial of the opening of the Congress by the Mayor, and the installation of the President, an adjournment was made to the public luncheon held at the Pavilion under the chairmanship of the Mayor, the large hall being quite full. The collation was abundant and good, but the caterer's charge for it (4s. 6d. *vin non compris*) was decidedly in excess of value given.

Sir William Preece's presidential address (which we print in abstract in this issue) was well designed and eloquently expressed. Not being a Medical Officer of Health or otherwise officially connected with sanitation, he did not attempt a scientific exposition of it, but devoted himself to an enunciation of its general principles and to the six requirements for the *mens sana in corpore sano*. In this he was very successful, his observations being systematic and lucid, and his foundation of these principles on the law of Moses, whom he described as "the greatest sanitary engineer the world has ever known," being particularly happy. We refrain from particularising his points as our readers can peruse them for themselves.

The evening of the first day (Tuesday) was assigned to the opening of the Health Exhibition, which function was officially performed by the Mayor. We shall notice the exhibition later on.

The scientific work of the Congress was conducted in a series of conferences and meetings of sections. The conferences included eight classes of sanitary officials: (1) Municipal representatives; (2) Port sanitary authorities; (3) Medical Officers of Health; (4) Medical Officers of Schools; (5) Sanitary Engineers and Surveyors; (6) Veterinary Inspectors; (7) Sanitary Inspectors; (8) Domestic Hygiene. It was understood that no one but the officials named should take part in the Conference with which they are in relation. The sections were three in number—(1) Sanitary Science and Preventive Medicine; (2) Engineering; (3) Physics, Chemistry, and Biology; and in the proceedings of these sections any member might take part. In the conferences many questions of great interest to sanitarians were discussed, e.g., housing of the working classes, sanitation of passenger ships, child labour and infant mortality, recrudescence of the plague in Europe, the repression of venereal disease, and the prevention of malaria disseminated by mosquitoes. The lion's share of the work of the Institution was, however, taken by the subject of tuberculosis viewed from one or other aspect. Precautions against its dissemination by (a) the human subject; (b) tuberculous meat; (c) tuberculous milk. (d) Sanatoria for phthisical patients, their maintenance and administration. On Thursday evening a public lecture on the subject was delivered by Mr. Malcolm Morris, F.R.C.S. He asked himself, "Is a crusade for the suppression of tuberculosis expedient?" and proceeded to establish, rather unnecessarily, the affirmative by adducing the statistics of the disease and the media for its dissemination, which are now arguments rather of historic than present interest. As to practicable means of "suppression," the lecturer had no suggestion worthy of special notice to offer. His panacea is the usual one of coercion—the enactment of laws to make spitting by consumptives an offence punishable by gaol, unless the unhappy victim expectorated into a leaf of antiseptic paper (carried home in his pocket for destruction) or in a spit cup carried in his hand. Some of the speakers at the sections elaborated this suggestion by adding the compulsory removal of all phthisical patients from their homes and their work, and their incarceration, at State expense, in sanatoria for an

unlimited period. All such suggestions are useful as an illustration of "how not to do it," of how to disgust the public, the Government, and the ratepayer with the consumption crusade. There are many alternative means which may, and must be adopted, e.g., education of the public on the subject through the Board Schools, interception of tuberculous meat and milk before it reaches the consumer, and provision of economical State-aided sanatoria for those who can afford to isolate themselves voluntarily. But these expedients are altogether too simple for the sanatorium extremists, whose motto is "the whole thing or none."

Our space does not permit us to do more than enumerate some of the most noteworthy papers read. The subject of the bacteriological treatment of sewage was the subject of a valuable discussion, on the initiative of Professor Frankland, which, we doubt not, will give a stimulus to the further investigation of the subject. Professor Simpson read an admirably practical paper on the recrudescence of the plague in Europe, and got a resolution passed in favour of a Government Commission to visit Portugal and investigate. The scientific work of the Congress wound up by a lecture by Baillie Dick, of Glasgow, on the Belvedere Infectious Disease Hospital of that city, which he illustrated by views on the screen of that institution in all its departments. The lecture was that of an enthusiast of his subject, admirably delivered, practically put, and enlivened by much dry humour. It was received by the somewhat limited audience with great approval, and, we doubt not, has left behind a desire to imitate Glasgow in the minds of those hearers who, unfortunately, have not the means of doing so.

THE HEALTH EXHIBITION

is established apart from the meeting hall of the Congress, and presents an exhaustive collection of apparatus required by the sanitary engineer. The greater part of it is occupied with competing exhibits of sanitary earthenware, but there is much else deserving of explanation and notice. The nursing division is especially worthy of examination.

There is, of course, the usual leaven of incongruous advertising stalls where sewing machines, knife cleaners, carpenters' tools, and cheap spectacles are puffed off. It seems to us that the admission of such catch-penny booths, which have nothing whatever to say to sanitation, are a blot upon such exhibitions, and that the cheap jack advocacy of wares across the counter should not at all be permitted. At one stall in this exhibition a vendor of cheap spectacles, who calls himself an "oculist-optician," was busy going through the usual farce of a twenty seconds test-type examination preparatory to the putting off of spectacles of which he might know nothing for the accommodation of eyes of which he probably knows less. We put it to future exhibition committees that the invasion of such stalls as this should be prohibited.

THE ENTERTAINMENTS.

As far as we could see the provision made by the local committee for the instruction of the members by inspection of works in action, and for their enjoyment out of business hours, were as nearly perfect as possible. The instructional part included visits to waterworks, sewage works, isolation hospitals, electric works, and Dr. Poore's sanitary garden; and the social relaxations comprised garden parties given by Lady Crichton at Netley Abbey, by Surgeon-General Nash and the medical officers at Netley Hospital; an At Home on board the splendid Cape Liner *Scot*, sea trips to the Isle of Wight, archaeological excursions to view the antiquities of the town, a visit to Osborne House, and an all-day drive through the New Forest, besides organised cycle excursions every day and everywhere. Unfortunately these entertainments were held in April weather; frequent sunshine interspersed with violent showers, but none of them were spoiled altogether by the elements.

THE LOCAL ADMINISTRATION.

It only remains for us to express, as we believe we do, the feeling of thanks and admiration felt by almost all

present for the efforts put forth by the local committee to make the Congress a success.

It is, we hope, not invidious for us to say that Dr. Wellesley Harris, Medical Officer of Health, took, naturally, the lead in organisation, and he and his colleagues may well be congratulated on a result which does them infinite credit.

Correspondence

We do not hold ourselves responsible for the opinions of our correspondents.

NURSES OF THE LATEST FASHION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In justice to any literary ability I may possess, will you allow me to state, that the abridgment which my stories relating to "Nurses of the Latest Fashion," have undergone—a curtailment, not by my hand—in THE MEDICAL PRESS has, in my opinion, seriously impaired their vitality and interest.

The portraiture drawn from life have thus been reduced to almost lifeless puppets by the loss of nearly all characterisation.

For instance, the husband huntress and trapper, in the pursuit of her game, as a private nurse, is shorn of the moral tone of her character by your having entirely omitted the portraiture of the "son" and the "father," on whom she successively tried her hand to get a husband in spite of their depravities. Nurse Lovibond, and how many more of her species seems to have entered the nursing vocation solely as a means for her intimate association with family life, thus to entrap the most eligible man into a legal union—with a good settlement.

I might notice your abridgement of each of the other stories as published. These important omissions will be more apparent if the whole were published in book form; but I trust you will, in fairness to me, publish this letter, with any comments you may be pleased to offer.

I am, Sir, yours truly,

FREDERICK J. GANT.

September 1st, 1899.

[After careful perusal of Mr. Gant's MS. we were compelled to curtail, first, on account of its extreme length; secondly, because much of the material was unsuitable for a medical journal, and many details were introduced which, however desirable in book form, were unnecessary in our columns for the purpose he had in view—i.e., that of calling attention to the necessity existing for the systematic registration of properly qualified nurses, in order that base characters may be eliminated from their ranks. Many of these nurse portraits were "untouched" by us, and we do not consider that the detailed descriptions of their victims were necessary in our columns, or that such omission detracted from the indictment which he penned.—Ed.]

Obituary.

PROFESSOR CUMING, OF BELFAST.

THE sudden death, on last Sunday week, of this most estimable member of our profession, has been sad news, not only for his family, but for all who knew him, professionally or socially. He had been in rather delicate health for a year past, but, on the day of his death, had been at his business in Belfast. On his return home he was seized with a violent fit of coughing, and died in a few minutes.

Professor Cuming held the Chair of Medicine in Queen's College, Belfast, until last winter, when he relinquished it and was succeeded by Dr. Lindsay. He was an Armagh man, born in 1831, and received his primary education in the Royal School there, and his

graduation education in both Arts and Medicine in the Belfast College. He also served as a pupil under Charcot. In 1865, he succeeded Professor Ferguson in the Professionate of Medicine—and in addition to all the honours which the North of Ireland had at its disposal he received the special distinction of Honorary Fellow of the Royal College of Physicians in Ireland, and, afterwards, held the Presidency of the British Medical Association at the Belfast meeting in 1884. He was put forward at the last election of a Direct Representative for Ireland on the General Medical Council, and he ran a very good second to Sir William Thomson. He was a Catholic in religion.

Very few men depart from the ranks of any profession amid more universal sorrow on the part of his brethren than Professor Cuming. He was essentially a gentleman and had all the attributes of such, besides that he was kind to all and an astute and thoughtful physician. He was quite incapable of making his professional position subservient to selfish or sordid ends, and was always ready to help his congeners with his best advice.

DR. HUGH CHARLES, J.P., COOKSTOWN.

This well-known North of Ireland practitioner met a shocking death at Oxford, whither he had come from his residence at Cookstown, co. Tyrone, in order to reside with his son. He arrived at Oxford on Saturday week and was found burned to a cinder in his bed on the succeeding Monday morning. He was 81 years of age, and had upset the lamp upon his bed.

DR. WILLIAM PARKER.

We regret to announce the death of Dr. William W. Parker, who died at Richmond, Va., August 4th, 1899. He was born at Port Royal, in 1824, graduated in 1848, and was connected with the well-known Bellevue Hospital, of that city, until about 1861. When the Confederate War broke, out he organised the famous "Parker Battery," which made a gallant record. The war ended, he resumed the practice of medicine in Richmond. He has filled every position of honour in the gift of the profession of his city and State. In the Medical Society of Virginia, of which he was a founder, he was its President for a term, and filled the position of Chairman of the Executive Committee for many years.

Laboratory Notes.

WHEATLEY'S NON-INTOXICANT DRINKS.

WE must acknowledge that we have been hitherto rather prejudiced against temperance beverages, of which our experience has been that they are usually not agreeable to taste or sight, and are, moreover, almost as expensive as the ale, porter, and light wine, which they are intended to supersede. We are, however, to some extent converted from this faith by an examination of Wheatley's well-known Hop Bitters and Stone Ginger Beer for which an opportunity was recently afforded us.

The Hop Bitters if not labelled or if called by another name, would hardly be distinguishable from any of the better class light pale ales. When decanted it is of the orthodox amber colour—perfectly clear and without sediment, and brisk in flavour, which is slightly of the Lager type. It is a very pleasant thirst-allayer, with none of the undesirable intoxicant quality, and its established popularity as a beverage ought to increase.

The Stone Ginger Beer may be said to be the stronger of the two drinks, for it is more pungent. It is opalescent when decanted, and we have noticed, in some of the samples a slight sediment arising—as we suppose—from precipitation of the ginger which it contains. It is much more pleasingly redolent of the real ginger than the ordinary syphon ginger-beer, and—we should expect—would be much preferred by the public.

These beverages bear their own testimony to quality, of which anyone can judge by giving them a fair trial. They appear to be both suitable as stomachic tonics, and entirely innocent of after dangers.

Literature.

GOWERS' NERVOUS SYSTEM. (a)

WE are glad to see a third edition of this well-known work, and in the assistance rendered by Dr. Taylor we have a guarantee of thorough revision with the assurance also that the ripe experience of Sir W. R. Gowers is made the most of. The first volume, dealing with Diseases of the Nerves and Spinal Cord, which is now before us, is well done. A short chapter is interpolated dealing with the modern conception of the elementary arrangement of the nervous system as the result of the labours of Golgi, Ramón y Cajal, Kölliker, and others, and though this chapter rather disturbs the arrangement of the others by its appearance in the wrong place, it is none the less welcome and not too long. The final twigs of the primitive fibrils are termed "anites," but this designation is not needed, and, indeed, a simplification of the terminology of neuropathology is very much to be desired. With regard to the author's views regarding the uncertainty of the nature of many of the small brain cells—whether nervous or neuroglial—we quite agree. The whole method of the book is very good, and while much of it may be passed over by the practitioner as beyond his interest, for many nervous diseases are rare, if he refers to it at all he is sure to be interested, not only because of the lucidity of style, but the really instructive and authoritative character of the page. If we take, for example, neuro-myositis, of which, by the way, some further speculation and detail might be forthcoming, and the various forms of neuritis which are here fully referred to, we have a fair conception of the thoroughly practical and scientific value of the work. For a third edition the book requires scarcely an introduction; but considering the amount of new matter which appears in it, we must draw attention to the fact that it is a third edition in the best sense of the term.

St. Thomas's Hospital.—House Appointments.

THE following gentlemen have been selected as house officers, their duties commencing yesterday:—

House Physicians: E. H. Ross, L.R.C.P., M.R.C.S. (extension); J. Gaff, L.R.C.P., M.R.C.S.; A. Bevan, L.R.C.P., M.R.C.S., and H. C. Thorpe, M.A., M.B., B.C., Cantab. (extension).

Assistant House Physicians: F. H. Ellis, B.A., M.B. B.C., Cantab., L.R.C.P., M.R.C.S., and B. F. Howlett L.R.C.P., M.R.C.S.

House Surgeons: H. J. Phillips, L.R.C.P., M.R.C.S.; P. W. G. Sargent, M.A., M.B., B.C. Cantab., L.R.C.P., M.R.C.S.; S. A. Lucas, L.R.C.P., M.R.C.S.; H. T. D. Acland, L.R.C.P., M.R.C.S.

Assistant House Surgeons: A. Webb Jones, L.R.C.P., M.R.C.S.; E. A. Gates, L.R.C.P., M.R.C.S.; E. C. Bourdas, L.R.C.P., M.R.C.S.; N. Unsworth, L.R.C.P., M.R.C.S.

Obstetric House Physicians: (Senior) H. M. Scaping, B.A. Cantab., L.R.C.P., M.R.C.S.; (Junior) A. E. Stevens, M.B. Durham, L.R.C.P., M.R.C.S.

Ophthalmic House Surgeons: (Senior) T. Hoban, L.R.C.P., M.R.C.S.; (Junior) J. A. Barnes, L.R.C.P., M.R.C.S.

Clinical Assistants in the Special Department for Diseases of the Throat: L. H. Lindley, B.A., M.B., B.Ch. Oxon. (Extension); C. L. Hawkins, B.A., Cantab., L.R.C.P., M.R.C.S. Skin: H. R. Beale, L.R.C.P., M.R.C.S. (Extension); T. Perrin, L.R.C.P., M.R.C.S. Ear: A. E. Martin, B.A., Cantab., L.R.C.P., M.R.C.S.

Students' Guide of the Royal College of Surgeons, Ireland.

THE "Medical Student" Guide," published by the Royal College of Surgeons, Ireland, has just been issued. The preliminary examination will be held on Wednesday and Thursday, September 27th and 28th, the winter session commencing in October. The "Medical Students' Guide" can be had free on written application to the Registrar, Royal College of Surgeons, Dublin.

(a) "A Manual of Diseases of the Nervous System." Vol. I. Edited by Sir W. R. Gowers, M.D., and James A. Taylor, M.A., M.D. Third Edition. London: J. and A. Churchill.

Notices to Correspondents, Short Letters, &c.

✎ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

LOCAL REPORTS AND NEWS.—Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sending them to the Editor.

THE SCOTTISH MEDICAL AND SURGICAL JOURNAL, LIMITED.

The *Financial News* publishes the following announcement:—Registered with a capital of £2,000 in 200 £5 preference shares and 1,000 £1 ordinary shares. Object, to acquire and carry on the journal now known as the *Scottish Medical and Surgical Journal*. Registered office: 43, Castle Street, Edinburgh.

DR. Y. J. SMITH.—The diagnosis of œsophageal ulcer, which you suspect, is as a rule difficult to arrive at. There is no absolutely pathognomonic symptom, and, indeed, in many instances the symptoms are so slight as to be altogether overlooked. Pain and vomiting after food are among the earliest symptoms, and later there is difficulty in swallowing, regurgitation of food and hæmorrhage. Stricture cannot be detected at this stage. Death may occur from exhaustion or perforation, or the ulcer may cure spontaneously. Treatment is practically the same as for gastric ulcer.

R. T. WILLIAMSON.—Before giving evidence in the case you had better consult Murrell's "What to do in cases of poisoning," and Husband's Forensic Medicine. Chronic coal-gas poisoning is a recognised condition. In acute cases the toxicity is probably due in great part to the carbonic acid contained (Murrell). Every practitioner should refresh his memory from time to time in the matter of poisons and their antidotes.

CHEMICO-MEDICAL MADRIGAL.

I know a maiden, charming and true,
With beautiful eyes, like the cobalt blue
Of the borax bead, and I guess she'll do
If she hasn't another reaction.

Her form is no bundle of toilet shams,
Her beauty no boon of arsenical balms,
And she weighs just sixty-two kilograms
To a deci-decimal fraction.

Her hair is a crown, I can truthfully state
'Tis a meter long, nor curly, nor straight,
And it is as yellow as plumbic chromate
In a slightly acid solution.

One day I said, "I will leave you for years,"
To try her love by rousing her fears;
She shed a deciliter of tears,
Turning brown the tumeric yellow.

To dry her tears, I gave her, you know,
A hectogram of candy; also,
To bathe her red eyes, some H_2O .

She said: "You're a naughty fellow."

I have bought me a lot, about a hectare,
And have built me a house ten meters square,
And soon I think I shall take her there,
My tart little acid radicle.

Perhaps little sailors in life's deep sea
Will be the salts of this chemistry,
And the lisp of the infantile A, B, C,
Be the refrain of this Madrigal.

Indian's Med. Journal.

EPEXEGESIS.—Comment of the kind you suggest would be most valuable to all concerned. We doubt, however, whether a book on therapeutics—even of an elementary kind—could be written on the lines indicated. The difficulty lies in the evidence. When so much illness is fleeting and symptomatic, who is to say what is the exact process of cure, or whether this or that drug has been the active curative agent?

OUR SPECIAL CORRESPONDENT.—We were reluctantly compelled to hold over your article on Brides-Salins on account of great pressure on our space.

PATERFAMILIAS.—The point is an important one, and we propose referring to it fully in our "Educational Number" next week.

A CORRESPONDENT signing himself "A Barrister" has omitted to enclose his card.

Vacancies.

Durham County Asylum, Winterton, Ferry Hill.—Assistant Medical Officer, unmarried. Salary £120 per annum, with apartments, board, and attendance. Applications to the Chief Medical Officer by Sept. 8th.

Folkestone, Victoria Hospital.—House-Surgeon. Salary, £80 per annum, rising to £100, with board, residence, and washing. Applications to the Secretary by Oct. 1st.

Great Yarmouth Hospital.—House-Surgeon. Salary £90 per annum, with board, lodging, and washing. Applications to F. E. Ferrier, Honorary Secretary, 33, Hall Plain, Great Yarmouth, by Sept. 23rd.

Hemel Hempstead: West Herts Infirmary.—House-Surgeon and Dispenser, unmarried. Appointment for two years. Salary, £100 per annum, with board, fire, light, attendance, and washing. Application to the Assistant Secretary by Sept. 13th.

Lancaster: Royal Albert Asylum.—Resident Medical Officer. Between 30 and 40 years of age. Salary, £400 per annum, advancing to £450, with furnished house, coals, gas, &c. Applications to the Principal and Secretary by Sept. 14th.

Portsmouth Borough Asylum.—Junior Assistant Medical Officer. Salary, £120 per annum, increasing to £150, with board, lodging, and washing. Application to the Medical Superintendent.

Preston Royal Infirmary.—Assistant House-Surgeon. Salary, £50 per annum, with board, lodging, washing, &c. Applications to the Secretary, 5, Winkley Street, Preston, by Sept. 13th.

Prestwich: Manchester County Asylum.—Assistant Medical Officer. Unmarried, and under 35 years of age. Salary £125, increasing to £250, with board, apartments, and washing. Applications to the Superintendent.

Stoke-on-Trent: North Staffordshire Infirmary and Eye Hospital, Hartshill.—House-Surgeon. Salary commencing at £120 per annum, with furnished apartments, board, and washing. Applications to the Secretary by Oct. 9th.

Trales Union.—Analyst to the Board of Guardians. Application to Clerk of Union. (See Advt.)

Westminster Hospital.—Pathologist. Salary, £250 per annum, and a sum of £80 per annum allowed for expenses. Applications to the Secretary by Oct. 1st.

Appointments.

CADDICK, C. J., M.B., C.M. House Surgeon to the Walsall and District Hospital.

CROWTHER, E. E., L.R.C.P. Edin., L.R.C.S. Edin., L.F.P.S. Glas. Medical Officer for the Luddenden District of the Halifax Union.

DU BUISSON, E. W., L.R.C.P. Lond., M.R.C.S. Eng., Medical Officer to the Dewchurch District of the Hereford Union.

HARRISON, H. F. E., L.R.C.P. Lond., M.R.C.S. Lond., Medical Officer for the Third District of the Parish of Hammersmith.

JONES, W. E., M.R.C.S., L.R.C.P. Lond., Senior House Surgeon to the Halifax Infirmary.

LONGFORD, J. M., L.R.C.P.I. & L.M., L.R.C.S.I. & L.M., Assistant Medical Officer of the Workhouse of the Halifax Union.

MAYNARD, G. D., M.B.C.S. Eng., L.R.C.P. Lond., Junior Out-patient Surgical Officer to the Royal London Ophthalmic Hospital, City Road.

NUTTALL, T. E., M.B., C.M. Edin., Medical Officer for the First Accrington District of the Haslingden Union.

REID, J., M.D. Glas., M.B., C.M., Medical Officer of the First District of the Parish of Hammersmith.

STEWART, J. B., M.A. Glas., M.B., C.M., Medical Officer of the Workhouse of the Haslingden Union.

STURGIS-WHITE, B., M.B., C.M. Edin., Medical Officer for the Cradley District of the Stourbridge Union.

Births.

ELKINGTON.—On September 2nd, at Newport, Salop, the wife of G. A. Elkington, M.B., of a daughter.

Marriages.

BARRY—LEPPINGTON.—On August 30th, at St. Mary Abbott's Church, Kensington, Jas. Wm. Barry, L.R.C.P., M.R.C.S., son of the late Dr. J. J. Barry, of Ramsgate, to Ann Elizabeth, daughter of the late Dr. H. M. Leppington, J. P., of Great Grimsby.

DENT—MITCHELL.—On August 31st, at St. John's Church, Clifton, Bristol, Ernest Albert Dent, M.B., C.M. Edin., of Cheltenham, to Mary Stewart Mitchell, third daughter of the late Captain J. M. Mitchell, of Georgefield, Uddingston, N.B.

MOORE—PRICE-DENT.—On August 31st, at Hallaton Parish Church, James Lennox Irwin Moore, M.B., C.M., of Market Harborough, son of the late George Moore, M.D., of London, to Georgina Roberta, daughter of the late Major-General R. H. Price-Dent, B.S.C., J.P., of Hallaton, Leicestershire.

MILTON—DE LA CONDAMINE.—On August 29th, at St. John's the Evangelist Church, Kingston-on-Thames, J. Pem Milton, L.R.C.P., M.R.C.S., son of J. P. Milton, of Lanoweth, to Alice Ellen, daughter of the late John de la Condamine, of Penzance, Cornwall.

SMITH—JOY.—On August 31st, at the Parish Church, Hempstead, Geo. Z. Smith, L.R.C.P., M.R.C.S., of Watford, to Edith Dora, daughter of David Joy, Esq., of 118, Broadhurst Gardens, Hampstead.

STEVENS—REEVES.—On August 31st, at St. Peter's Church, Eltham, Thomas George Stevens, M.D. Lond., F.R.C.S. Eng., M.R.C.P. Lond., of 8, St. Thomas's Street, London, S.E., eldest son of G. J. B. Stevens, M.R.C.P. Eng., L.R.C.P. Lond., of Newington Green, N., to Lizzie, eldest daughter of John Reeves, Esq., of Ecclesbourne, Lee, S.E.

Deaths.

MACWHARRIE.—On August 28th, at Toftcombs, Biggar, N.B. Robt. MacWharrrie, M.D., Deputy Inspector-General of army hospitals.

ERSKINE.—On August 28th, at his residence, Bournemouth, John Low Erskine, M.D., Deputy Surgeon-General Army Med. Dept. Retired.

STUART.—On August 29th, at his residence, Wigan, John Stuart, M.D., J.P. for the County and Borough of Wigan, aged 45 years.

No. 11.

STUDENTS' NUMBER.

INTRODUCTORY REMARKS.

It is customary to devote one number in each year of a medical journal to the subject of medical education, and tradition has assigned the month preceding the opening of the medical schools as the date best suited for the purpose. Why this should be so it is not altogether easy to explain. The information brought together in this number is unquestionably of the greatest utility to those who contemplate taking up medicine as a study or who may be interested in the subject indirectly in the capacity of parents or guardians, but it may be assumed that the necessary arrangements will have been made ere this. Be that as it may, there is a sufficient element of incongruity in the details of the curriculum for an annual synopsis to be necessary, and this we have prepared with the greatest care with a view to bringing it up to date. In most instances the corrections have been made by the secretaries of the various institutions, and in the others the requirements have been collated with the official schedules of studies.

We have not been enabled to embody the modifications which the new scheme for a teaching university for London must entail in the regulations because the scheme is still being elaborated, and some time must still elapse before it can be promulgated, but we have the satisfactory assurance that by this time next year the reconstituted university will be in working order, a dream long caressed by those who are interested in the medical schools of the metropolis. It will then remain to be seen whether the result of so many years' agitation will confer upon London students advantages at all commensurate with the expenditure of time and energy involved.

We are evidently, though slowly, approaching a one-portal system, in that each year shows a more marked preference on the part of students for a degree in medicine rather than a mere diploma; not, indeed, that there is any essential difference between the professional knowledge which they respectively imply, but in deference to the opinion generally received among the public that a doctor of medicine stands higher than a diplomate. There used, indeed, to be a difference—at any rate, in regard to general culture—but we doubt if that obtains at present. Nevertheless, the fact remains that a diplomate on entering practice finds himself in a somewhat invidious position. He has no right to the prefix "Dr.," and though many nowadays do not hesitate to make use of the titular designation, the diplomate who does so exposes himself to the charge of pretending to be that which he is not. By-and-bye, as the teaching and degree-conferring bodies become merged and

affiliated, it will be open to every student to enter for the course of study and examination which, without any greater strain than is at present put upon the candidate by the conjoined examining boards, will ultimately invest them with the uncontested right to the distinction. The fellowships of the colleges will still enable those who propose to tread the higher walks of the profession to distinguish themselves from their fellows, and the extension of the system of more or less unauthorised diplomas in special subjects will furnish evidence of special study. In most other countries the doctorate of medicine is the only recognised qualification for practice, and not until a similar evolution has taken place in this country will existing chaos give place to orderly simplicity.

The main lines of medical education are determined by the General Medical Council, and are uniform for the United Kingdom. It is, therefore, to the regulations issued by that body that the student must turn for detailed information. The first step, the indispensable condition for admission to the *Students' Register* is the Preliminary Examination in General Education. Until this has been passed in accordance with the requirements of the Council, no time spent in study or in attending lectures will be allowed to reckon as part of the prescribed five years of medical study. The minimum standard of general education accepted by the Council is still shockingly low, and there is an inexplicable reluctance on the part of the Council to bring about any substantial improvement in the standard. When this examination has been passed and registered, there remains the choice of a medical school. In many instances this choice will doubtless be determined by purely geographical considerations, but apart therefrom there remain to be considered the advantages attaching to a large, as compared with those peculiar to a comparatively small, school. To a student of sound physique, energy, and talent the large school unquestionably offers advantages which are denied to the smaller institutions. The prizes are more numerous and substantial, there is greater scope for competitive work, and the successful student has the inestimable advantage of coming into contact with the most eminent representatives of the professional men in whose power it is, later on in his career, to afford him material assistance. The small schools on the other hand allow of a more intimate relationship between teacher and pupil, the conduct of each individual student is under close surveillance—a point of some importance to parents—and a much larger proportion of the students are afforded an opportunity of acquiring the invaluable experience which is alone to be acquired by holding resident appointments.

It is important to remember that the student must make up his mind before entering on his medical studies as to the goal to be striven for, that is to say, whether he will content himself with a simple licence to practise or whether he will make the additional sacrifice of time and money which the possession of an university degree usually implies. To swerve from an original plan almost always entails unavoidable loss of time, inasmuch as the university examinations have to be passed at stated intervals.

At most schools there are entrance scholarships, many of considerable value, awarded on the strength of competitive examinations in the subjects of general education, but the selection is usually made some weeks before the date for opening the schools. Prizes are also awarded at the end of each session for proficiency in each branch of study, together with scholarships which are periodically thrown open to competition. It is well for the energetic student to acquaint himself with the conditions under which these may be competed for early in his course, for they constitute a valuable incentive to exertion. At the end of his student's career, should circumstances allow of his doing so, the newly qualified man will aim at obtaining a nomination to one or other of the resident appointments. These, of course, are reserved to the few, but the practical experience which they confer and the confidence which such experience begets, are to be obtained in no other way, and we would strongly advise all who are not otherwise prevented therefrom to do their best to crown their student career by serving their hospital in this capacity.

THE COURSE OF STUDY.

Students who enter for the winter session will devote most of their attention to anatomy and physiology, and it will be found greatly to their interest to have got rid of the preliminary scientific work—chemistry, physics, and biology—before entering upon the study of these two engrossing branches of medical study proper. Anatomy and physiology constitute the bases of medicine and surgery, and their importance as subjects of study cannot be overrated. On the way in which this part of his work is done will depend to a large extent the success of the student's subsequent career. It is in the dissecting room that he learns the importance of direct personal observation, and no amount of mere book work will adequately replace the methodical investigation of human anatomy. Text-books and atlases ought to be regarded only as guides to dissection and never as a substitute therefor. The late Mr. Thomas Cooke rightly raised his protest against the modern tendency to scamp actual dissection in favour of mere book work, and we have always endorsed his contention that the tendency was one to be deplored. The first thing, therefore, that the student should do on joining a school is to arrange for a "part," because the supply of subjects is rarely equal to the demand, and the last comers are left out in the cold, and may have to wait for weeks, or even months, before they are able to begin practical work. The study of the dry bones will first engage the student's attention. If somewhat arid, the subject is an indispensable preliminary to that of the structures which normally envelop them, and the facts which the student is required to consign to memory are peculiarly elusive, and require many sturdy efforts before

they become finally incorporated in his mind. Here, as elsewhere, method is everything. The burden of study sits lightly upon those who work systematically, and attempts to assimilate the myriad details in a short space of time is sure to prove a disastrous failure.

By the time the student has passed the examination in anatomy and physiology at the end of the second academical year his transfer to the wards will come as a pleasant change. He passes from theory to practice, from the dissecting room, with its unenticing associations and total lack of animation, to the wards, replete with living, suffering, but always interesting, specimens of humanity, each with his tale of woe. It will be his privilege to unreeve the tangled threads of each story, and to record all that may assist in elucidating the problem before him, for every patient is a problem. And let the student never for one moment allow himself to forget that in the patient whose "case" he is taking he is dealing with a man and a brother. Suffering is democratic in its incidence, and should always be treated with respect in the person of its victim. It is rare that one has to reproach the medical student with downright heartlessness; his sins, such as they are, are usually due to thoughtlessness and want of tact. He who has once taken to heart the terrified look of the unhappy sufferer, the gloom and hopelessness of whose destiny has been suddenly revealed to him by a careless word at the bedside, will be careful never again to inflict this cruel pang.

CLINICAL WORK.

Nowhere is thoroughness more necessary than in clinical work. The student has before him in each patient the means of acquiring practical knowledge, but the value of the opportunity depends absolutely on his ability and his willingness to observe. The object and aim of his clinical training is to learn how to observe. The difference between a trustworthy practitioner and the other lies mainly, if not entirely, in the fact that one observes and the others do not. This faculty is one which can be acquired and vastly improved by systematic training, and the training consists in observing faithfully and carefully every case.

THE POST-MORTEM ROOM.

We would strongly advise every student to spend as much time as possible during the last three years of his studies in the post-mortem room. The post-mortem room is the natural complement of the clinical wards, it is often only in the room that the clinical problem is unravelled, it is there that the student can see for himself the physical result of the processes of disease which he has been watching at the bedside. He learns too, as he can never learn in the dissecting room, to recognise the post-mortem appearances of the various viscera, and to distinguish between changes due to decomposition and those caused by the ravages of disease. The lack of this familiarity has over and over again led to errors of the gravest kind, errors which have had for effect to jeopardise the administration of justice and perchance to place innocent persons in the most serious predicaments.

Lastly, the conscientious student should avail himself of every possible opportunity to acquire experience in the administration of anesthetics. He can do this with a minimum of risk to the patients in hospital

where his earlier steps will be taken under the supervision of skilled and experienced persons. Let him never forget that the various anæsthetics are lethal drugs if improperly or incautiously used. Let him remember that he has no more right to administer chloroform recklessly than to dispense with the use of the measure when about to administer strychnine solution or other violent poison. Many of the mishaps which are daily occurring are, it is to be feared, the result of ignorance or carelessness. Every practitioner is sure to be called upon to administer an anæsthetic at some time or another, and it behoves him, therefore, to ensure that his doing so does not expose his patient to any unnecessary risk.

THE SERVICES.

For a certain proportion of young medical men the Services will be certain to offer invincible attractions. The remuneration is fair, and the duties, for the most part, not of too exacting a nature; and last, but not least, there is a security of tenure which does not obtain in private practice. The past year has brought to pass a reform which had long been agitated for in the Army Medical Service, which had deservedly become so unpopular that the greatest difficulty was experienced in filling up the vacancies; indeed, even at the present time, a large number remain unfilled. We need not go into ancient history as to the reasons for this unpopularity, suffice it to say, that the Service has been transformed into a Royal Corps, the officers of which are described by corresponding military titles. It is hoped that under the new *régime* the old spirit of discontent will give place to a happier state of things, and that the Service will once more regain its popularity.

In addition to the Army and Navy, there is the Indian Medical Service, which annually attracts the *élite* of our young surgeons, and there are medical appointments in the colonies details whereof will be found elsewhere.

POST-GRADUATE TUITION.

ONE of the most remarkable features in medical education during the past few years is the growth in popularity of the system of post-graduate teaching. It would seem that the medical authorities in the metropolis have at length awakened to the fact that a demand exists for such teaching, and that the time has arrived to deal with it on a scale commensurate with its importance. That no facilities of the kind were available a few years ago for alien practitioners who visited this country for the purpose of improving their knowledge was a condition of things which compared very unfavourably with the Continental homes of medical learning—and thus it has come to pass that foreign medical men have never been attracted to London for the purpose of study, nor even of following the hospital practice of those British practitioners whose names happen to be well known for distinguished work. This reproach has now to some extent been done away with, at any rate in London. Post-graduate lectures have been organised in connection with many of the large general hospitals, and a focus of post graduate work has been constituted at the Polyclinic, in Chenies Street, which promises to develop into an important centre of study within the near future.

LONDON SCHOOLS.

The Schools of Medicine in the Metropolis are the following, the scholarships, prizes, students' appointments, fees, &c., being set forth in connection with each place named. The names of the hospital staff, lectures, residential, and other detailed information, will be generally found in our advertisement columns.

ST. BARTHOLOMEW'S HOSPITAL.—This hospital has 750 beds, and for many years past the school attached has occupied the enviable position of being the most popular with students, and of having a larger number of entries than any other medical school in London. Collegiate residence is here permissible, subject to the ordinary rules. A recreation ground for the use of students has recently been purchased at Winchmore Hill.

Appointments.—Ten house physicians and ten house surgeons are appointed annually. During the first six months of office they act as "junior" house physicians and house surgeons, and receive a salary of £25 a year. During their second six months they become "senior" house physicians and house surgeons, and are provided with rooms by the hospital authorities, and receive a salary of £80 a year. A resident midwifery assistant and an ophthalmic house surgeon are appointed every six months, and are provided with rooms and receive a salary of £80 a year. Two assistant anaesthetists are appointed annually, and receive salaries of £120 and £100 a year respectively. An extern midwifery assistant is appointed every three months, and receives a salary of £80 a year. Two assistant electricians are appointed every six months, and in-patient dressers, in-patient clinical clerks, clerks and dressers to the assistant physicians and to the physicians and surgeons in charge of special departments are appointed every three months without fee.

Scholarships, &c.—There are four open scholarships in science, £75, £75, £150, £50, in biology, chemistry, physics, and physiology, tenable for one year, and a Jeaffreson exhibition, value £20; four junior scholarships, of £30, £25, £20 and £10, respectively; Treasurer's prize for practical anatomy; Foster prize in practical anatomy; senior scholarships, value £50, for anatomy, physiology, and chemistry; Wix prize; Hichens prize; Lawrence scholarship and gold medal, value 40 guineas, for medicine, surgery, and midwifery; two Clakenbury scholarships, of £39 in medicine and surgery; Bentley prize, for reports of surgical cases; the Kirkes gold medal for clinical medicine, with scholarship of £30. Shuter scholarship of £50; Skynner prize of £15; Sir G. Burrows' prize of £10 and Matthews Duncan medal and prize, value about £20; the Treasurer's Research Studentship, of the value of £100 is given annually, the elected student being required to engage in original research in pathology.

Fees.—Fees for perpetual attendance on lectures and hospital practice, 160 guineas, payable in the following instalments:—First year, 40 guineas; second year, 40 guineas; third year, 40 guineas; fourth year, 40 guineas; or a single payment of 150 guineas. Fee for general subjects for students of dental surgery: First winter, 31½ guineas; first summer, 31½ guineas; or a single payment of 63 guineas. Fee to University students, 80 guineas; Fee for laboratory instruction for D.P.H., 20 guineas; Composition Fee to University of London students for one year's instruction for the Preliminary Scientific Examination, 20 guineas. Composition fee to University of London students who have passed the preliminary scientific examination, 150 guineas.

The Warden, Dr. James Calvert, will furnish further details on application.

CHARING CROSS HOSPITAL.—The school attached to this hospital is situated in central London, and contains new physiological, pathological, and bacteriological laboratories, *materia medica* museum, an anatomical theatre, enlarged dissecting-room, and chemical theatre. The hospital, which is now being enlarged, contains 180 beds, making, with the 30 beds at the adjoining Royal

Westminster Ophthalmic Hospital (to the practice of which general students are admitted free) a total of 210 beds available for clinical study.

Clinical instruction is given in medicine, surgery, and obstetrics, and in the special department, diseases of the skin, diseases of children, the throat, the nose and ear, and in the orthopaedic, Röntgen, and electrical departments.

Scholarships, Medals, &c.—Five entrance scholarships, the Livingstone scholarship, 60 guineas, and 55 guineas; Huxley scholarship, 40 guineas and 30 guineas. Three (100 guineas, 60 guineas, and 40 guineas) are open to all general students, one (55 guineas) is reserved for the sons of medical men, and one (30 guineas) is open to dental students only. All are awarded annually. Two University Scholarships, value 60 guineas each, are open to students from the University of Oxford who have passed the 1st M.B., to students of the University of Cambridge who have passed the 2nd M.B., and to students of the University of London who have passed the intermediate examination in medicine. Candidates must give notice to the librarian of their intention to compete on or before September 23rd, 1899. The Golding Prize of £10 is open to students at the end of their first winter session. The Huxley Medal, with prize of £10, is open to students at the end of their second winter session. The Pereira Prize of £5 is open to all general students. The Llewellyn Prize of £25 is awarded annually. The Governors' Clinical Gold Medal is open to students at the end of their fifth winter session. And a silver medal, or its equivalent in books, is awarded to the most distinguished student in each class.

Appointments.—The curator and pathologist is appointed annually, and receives £100 a year; medical and surgical registrars to the hospital receive £40 a year each, with luncheon in the hospital; six house physicians, six house surgeons, and two resident obstetrical officers are appointed each year; clinical clerks, dressers, and surgical ward clerks are appointed in all the general and special departments of the hospital.

Fees.—For the curriculum of study required by the various examining bodies and hospital practice, 110 guineas in one sum, or 121 guineas in five instalments.

The composition fee for sons of registered medical practitioners is 100 guineas, and the fee by instalments 110 guineas.

ST. GEORGE'S HOSPITAL.—This hospital is situated in a favoured position in the West End, facing Hyde Park. It contains 350 beds, and special wards for ophthalmic cases and diseases of women.

Appointments.—Four house physicians and four house surgeons, entitled to reside and board in the hospital free of expense; two assistant house physicians, two assistant house surgeons, four assistants in the special departments. Candidates for the above offices are selected quarterly by competition from among the perpetual pupils, and hold all the offices in succession during a period of two years, sixteen pupils being in office at any one time. Obstetric assistant with a yearly salary at the rate of £100 and board and residence in the hospital; pathological curator with a salary of £50; assistant curator with a salary of £30; two medical registrars, with salaries of £50 and £30 per annum; a surgical registrar with a salary of £50 per annum; an administrator of anaesthetics with a salary of £50 and two with salaries of £30 per annum; a surgery officer with a salary of £100 a year; three demonstrators of anatomy with a salary of £50 each; and assistant demonstrators. All offices are open to candidates without additional fee.

Exhibitions, &c.—The Brown exhibitions, one of £100 per annum, tenable for two years, and open to perpetual pupils possessing a registrable diploma; and one of £40 per annum, tenable for three years and open to students in their third year. The Brackenbury prizes of the value of £40 each, one each in medicine and surgery. The Webb prize in bacteriology, value £30. The Clarke good conduct and clinical work prize in surgery, the Thompson medal, the Brodie clinical prize in surgery, the Acland clinical prize, the Johnson prize in Anatomy, the Pollock

prize in physiology, the Treasurer's prize for clinical reports, and four general proficiency prizes of ten guineas each.

Scholarships.—One in arts of £150 for sons of medical men who have entered the school during the current year. Two in arts of £50, open to commencing students. Examination, September 26th. Two of £85 in anatomy and physiology, open to students who have signed up for or passed the first M.B. Oxford or second M.B. Cambridge. Two of similar value for students of Provincial University colleges of similar standing. Examination, October 3rd.

Fees.—Composition fee for perpetual pupils, £150, or £160 in the following instalments: First year £50, second year £50, third year £40, fourth year £20. The fee for general subjects in dental surgery is £55, payable in two instalments: first year £30, second year £25. Only perpetual pupils can hold house office or compete for the Brown exhibitions.

GUY'S HOSPITAL.—This hospital is situated on the Surrey side of London Bridge, and contains 546 beds with special wards for ophthalmic and obstetric cases. Attached to the hospital is a large residential college with rooms for about sixty men, whilst for students who prefer to live in the suburbs, no other hospital is so conveniently placed, the railway accommodation being good and close at hand. There is now a complete School of Dental Surgery at this Institution, which is recognised by the Royal College of Surgeons of England, the facilities thus afforded of completing the whole course of dental study within the walls of one hospital, and the professional and social advantages to the dental student of a close connection with a large school of general medicine and surgery have already led to a considerable entry of students in this department.

Re-opened Ward.—One of the wards which have for many years been closed for want of funds was re-opened in October last as a special ward for diseases of women, eight beds being set apart for difficult cases of labour. An obstetric registrar and tutor and an ophthalmic registrar and tutor have recently been appointed to augment the teaching in the special departments.

Appointments.—Eight house surgeons, eight house physicians, eight assistant house physicians, twenty-four assistant house surgeons, eight obstetric residents, twenty-four clinical assistants, and ninety-six dressers are selected annually from the students according to merit, and without payment. There are also a large number of junior appointments, every part of the hospital practice being systematically employed for instruction.

Scholarships.—Open scholarships of £100 or £50 in classics, mathematics, and modern languages. Open scholarships of £150 and £60 in chemistry, physics, and biology, and an open scholarship of £50 for University students in two of the following subjects:—Anatomy, physiology, organic chemistry, zoology, physics. Six scholarships, varying in value from £10 to £25 each, for general proficiency in medical study, open to students of different years. The Treasurer's gold medal in medicine; the Treasurer's gold medal in surgery; the Sands Cox scholarship of £15 per annum for three years for physiology; the Michael Harris prize of £10 for anatomy; Beaney prize in pathology, 30 guineas; the Beaney scholarship in materia medica, 30 guineas; the Bredin prize for clinical study, £25, the Golding-Bird gold medal and scholarship (£20) for sanitary science; and the Gull Research scholarship of £150 per annum. The Physical Society awards two prizes, each of £5 to the authors of the best essays on selected subjects, prizes of £10 and £5 for the best papers read before the Society, and a prize of £5 to the member who has most distinguished himself in the debates of the session.

New School Buildings.—A considerable addition to the school buildings was opened in 1897, comprising a series of class-rooms, laboratories, and a lecture theatre for the teaching of physiology.

Fees.—For the entire course of lectures and hospital practice, 150 guineas, if paid in one sum on entrance; or payment may be made by four instalments of 40 guineas

each, payable at the beginning of the first, second, third, and fourth years respectively.

KING'S COLLEGE HOSPITAL.—This hospital is centrally situated, being contiguous to the Royal College of Surgeons, Lincoln's Inn Fields, and the New Law Courts, Strand. The College adjoins Somerset House, and is close to the hospital. There are 220 beds; ophthalmic, ear, throat, skin, and dental departments, are attached to the hospital. Some wards are specially devoted to children's diseases, and ophthalmic diseases.

Scholarships.—£800 are awarded annually in scholarships and prizes. At entrance two science exhibitions of £60 and £40 value are open to all candidates under the age of nineteen; two scholarships of the value of £75 each (subjects literary) and two exhibitions of the value of £60 and £40 each (subjects scientific) are open to students commencing their curriculum. Two scholarships, value seventy and sixty guineas, are open to students of a British University who come up to London to complete their curriculum; two junior scholarships of £20 each for first year students, one of £30 for second year students, one of £50 for third year students in residence, and one of £40 for fourth year students. In addition students may compete for the Daniell scholarship, value £40; the Warneford prizes, value £40; the Rabbeth scholarship, value £20; the Carter, Todd, Jelf, Tanner, Leathes prizes, and all class and clinical prizes.

Appointments.—Medical and surgical Sambrooke registrarships, tenable for two years, each £50 per annum. Resident hospital appointments, viz., senior and junior house physicians, assistant house physician, physician accoucheur's assistant and assistant house accoucheur, and three house surgeons with free board and residence at the hospital; and senior and junior clinical assistants in special departments.

Residence of Students.—There are chambers allowing some students the opportunity of residing at the College.

University of London.—Special courses of lectures and practical instruction in the chemical, physical, and physiological laboratories have been arranged for students preparing for preliminary scientific and intermediate science examinations of the University of London.

LONDON HOSPITAL.—This hospital is the largest in the United Kingdom, containing as it does 800 beds. It has, moreover, wards and a teaching staff for almost every special department in the domain of medicine; the scholarship and prizes are many and valuable, and school and staff are alike deservedly popular with the students.

Scholarships and Prizes.—At Entrance.—Price scholarship in science, £120; Price scholarship in anatomy and physiology, £60; entrance scholarships in science, £60 and £35; Epsom scholarship, £126; Buxton scholarships in arts, £30 and £20. After entrance—Anatomy and biology scholarship, £20; anatomy and physiology scholarship, £25; Letheby prize, senior, £20; Letheby prize, junior, £10; scholarship in clinical medicine, £20; scholarship in clinical surgery, £20; scholarship in clinical obstetrics, £20; Duckworth Nelson prize, £10; Hutchinson prize, £35; Sutton prize, £20; Sir Andrew Clark, prize, £26; Anderson prizes, £9, Out-patient dressers' prizes, £60; practical anatomy prizes, £10.

Appointments.—The "House" appointments, which are more numerous than at any other hospital in the Kingdom, are made without fee of any kind, and all resident officers are provided with free board and rooms, and in a few instances with a small salary also.

Additional buildings for the department of public health, for the biological, chemical, and physical laboratories, materia medica museum, &c., and a new bacteriological department with general laboratory, research laboratories, class rooms for D.P.H. work, sterilising room, animal room, &c., have just been erected and are now open. For all these departments, special teachers have already been appointed who are devoting their entire time to the particular subjects that they have undertaken. In addition to these alter-

rations and additions, arrangements have been made in the hospital for additional clinical teaching.

Fees.—Perpetual fee for lectures, demonstrations, and Hospital Practice, payable in three instalments of 45, 45, and 40 guineas at the commencement of the 1st, 2nd, and 3rd years respectively, 130 guineas; or if in one payment, 120 guineas. A reduction of 8 guineas for chemistry and physics, and 5 guineas for elementary biology, is made from the above fees, in the case of students who have passed in these subjects at the First Conjoint Examination before entering the College. Fee for students entering in their third year (their first and second years having been spent at a recognised medical school elsewhere), 60 guineas. (This fee is payable by students entering who have passed the first M.B. Oxford; the second M.B. Cambridge; or the Intermediate M.B. London.) Fee for University students for hospital practice and appointments, 50 guineas. Dental students (general hospital practice and lectures), 40 guineas. General fee for dental practice, 10 guineas.

Note.—A reduction of 50 guineas will be allowed to the sons of medical men from the perpetual fee if paid in full, or 5 guineas from each instalment.

Special entries can be made either for single courses of lectures or for hospital practice.

Accommodation is obtainable at a very reasonable rate close by, or in the suburbs a few minutes' distant by train. Dinners and luncheons are provided in the Student's Club, which, with the reading and smoking-rooms, now form part of the college buildings. Students wishing to reside with a member of the profession can obtain information as to vacancies and terms from the Warden. A list of approved lodgings is kept. All inquiries should be addressed with reference to these and other matters to the Warden. The "London Hospitals' Club Union" has a field for cricket football, &c., with an excellent pavilion, at Lower Edmonton. The clubs and societies are open to all the students, and are warmly encouraged by the staff. Full particulars of the Warden, Dr. Munro Scott.

ST. MARY'S HOSPITAL.—This hospital is situated at Paddington, near the terminus of the Great Western Railway, and contains 281 beds, of which 128 are devoted to medical and 153 to surgical cases. A fresh Laboratory, fitted with electric light and all modern improvements, for the study of biology, pathology, and bacteriology, has recently been added, and also a new physiological theatre. The whole of the building hitherto used for the Out-Patients' Department of the Hospital has been apportioned to the Medical School for the purposes of new laboratories, class-rooms, and a new museum. There are also special wards for the diseases of women and children, and a new and very extensive out-patient department.

Appointments.—There are, in addition to clinical clerks and dressers, appointments in the hospital each year open to students as house physicians, house surgeons, and obstetric officers, free of all expense for board and residence. Two paid prosecutors or more as occasion arises are appointed annually; two demonstrators of anatomy, receiving £70, and one junior, £50; also two or more assistant demonstrators of anatomy; a demonstrator of physiology is appointed with an annual salary of £100, and two or more assistant demonstrators.

Scholarships, &c.—One scholarship in natural science, of the value of £144, open to any gentleman who has not completed a winter session of study at a medical school. Two scholarships in natural science, each of the value of £78 15s., and one of £52 10s., under the same conditions. One scholarship of the value of £144 open to students from Epsom College, being sons of medical men, and who have not completed a winter session of study at a medical school. Two scholarships, each of 55 guineas, open to students from the Universities of Oxford and Cambridge, who have not entered at any London medical school. All these scholarships are awarded by examination on September 20th and 21st.

Fees.—Fee for attendance on the full five years' curriculum of hospital practice and all lectures, demonstrations, and all classes of the medical, surgical, and

obstetric tutors given in the school and hospital, including membership of the Library, Medical Society, Students Club, and all the athletic clubs, and the receipt of the hospital *Gazette* for five years, £139 paid on entering the school; or in instalments, £144. The only additional fee is one of £3 3s. for those desirous of taking up a course of dispensing in the dispensary of the hospital.

Students who have completed the examination in anatomy and physiology at the Universities of Oxford, Cambridge, or other University, are admitted as perpetual pupils of this hospital and Medical School on payment of a fee of 55 guineas in one sum, or pay an annual fee of 28 guineas. University students, prior to completing the anatomy and physiology examinations, pay an annual fee of 28 guineas. After completing the anatomy and physiology examinations the inclusive fee or the annual fees detailed above may be paid.

Residential College. Gentlemen desirous of entering the residential college pay £75 for the academic year.

MIDDLESEX HOSPITAL.—This hospital, which is conveniently situated in the centre both of business and residential London, contains 320 beds. There are special departments for cancer, and for ophthalmic, throat, aural, skin, dental, and children's cases. Wards are also devoted to cases of uterine disease and of syphilis. The medical school buildings have been considerably enlarged and improved during the last twelve months. The new dissecting-room and pathological, bacteriological, physiological, and chemical laboratories are now in regular use. Residence for students is here obtainable in the college buildings attached to the school, additions to which have also been decided on.

Appointments.—Casualty surgical officer, casualty medical officer, six house surgeons, six house physicians, and two resident obstetric physicians. The above officers have residence and board in the college free of expense. Clinical clerks and dressers in all the departments are also appointed in addition to the foregoing.

Scholarships, &c.—Two entrance scholarships of the value of £100 and £60 respectively. One entrance scholarship of the value of £60, open to Oxford and Cambridge students only. (Subjects—Anatomy and physiology, including histology.) Two Broderip scholarships of £60 and £40 respectively, for medicine and surgery; John Murray medal and scholarship, awarded every third year; the Governors' prize of £21 for students in their final year. Hetley clinical prize, value £25, awarded annually for proficiency in practical clinical medicine, surgery, and obstetrics; the Lyell Gold Medal in surgery and surgical anatomy; the Leopold Hudson prize, value 11 guineas, in surgical pathology, including bacteriology; Freeman scholarship, £30, in obstetrics and gynaecology; exhibitions of 10 guineas and 5 guineas for anatomy and physiology to second and first year's students respectively, as well as class prizes in all subjects.

Fees.—General fee for the entire course of hospital practice and lectures, 135 guineas if paid in one sum on entrance, or by instalments of 60, 50, and 35 guineas, payable at the commencement of the first, second, and third years respectively. General fee for members of a University who have completed one year of medical study, 90 guineas if paid in one sum, or by instalments of 60 and 40 guineas. For those who have completed their anatomical and physiological studies the fee is 70 guineas on entrance, or in two instalments of 40 and 35 guineas. The composition fee for London University students who have passed the preliminary science examination is 115 guineas. The fee for the curriculum for dental students is 54 guineas on entrance, or two instalments of 40 guineas and 20 guineas.

ST. THOMAS'S HOSPITAL.—This hospital with its medical school attached is situated on the southern embankment of the Thames, facing the Houses of Parliament, and contains 572 beds.

The school buildings, which are separated from the hospital by a quadrangle containing a lawn tennis court for the use of the residents, comprises numerous theatres, laboratories and class rooms, and are well adapted for the modern teaching of large bodies of students in all the subjects of the medical curriculum. A large library and

reading room and a very complete museum are open to all students. The new club premises, opened in 1894, contain a dining room, a smoking and reading room supplied with daily and illustrated weekly papers, and a gymnasium.

A clinical laboratory has been recently built, in which, all the more difficult methods of diagnosis, bacteriological, chemical and microscopical, are carried on under the direction of a superintendent. The department for out-patients has been re-arranged, so that large numbers of students are enabled to follow closely the practice and teaching of the assistant staff.

Appointments are open to all students. A resident assistant physician and a resident assistant surgeon are appointed annually at a salary of £100 with board and lodging. Two hospital registrars, at an annual salary of £100 each are appointed yearly. An obstetric tutor and registrar is appointed each year at an annual salary of £50. The tenure of these offices may be renewed for a term not exceeding three years. Four house physicians, two assistant house physicians, four house surgeons, four assistant house surgeons, two obstetric house physicians, two ophthalmic house surgeons and eight clinical assistants in the special departments are appointed every three months. Clinical clerkships and dresserships to in and out-patient departments are available to the number of more than 40 each year.

Scholarships, Prizes, &c.—Three Entrance Scholarships are offered for competition in September, viz.: one of £150 and one of £60, in chemistry and physics, with either physiology, botany, or zoology at the option of candidates for first year's students. (The Medical School Committee is empowered to grant an exhibition of £20 to any unsuccessful competitor who obtains sufficient marks to qualify for a scholarship): one of £50 open to University students who have passed in anatomy, physiology, materia medica and pharmacy for a medical degree in any of the Universities of the United Kingdom and have not entered as students in any London medical school. Copies of the examination papers of last year may be obtained on application to the medical secretary. Applications must be sent in not later than September 19th, with certificate of birth and of preliminary examination, and in the case of candidates for the Science scholarships with a notification of their choice of optional subject. Numerous scholarships, prizes, and medals are open to competition throughout the whole career of a student, including a Fellowship of £100 given by the Salters' Company for research in pharmacology.

Fees.—The fees may be paid in one sum or by instalments. Entries may be made separately to lectures or to hospital practice. Special arrangements are made for students from the Universities and elsewhere entering in their second or subsequent years, also for dental students and for qualified practitioners.

Special classes for the preliminary Scientific and Intermed., M.B.Lond. for the Oxford and Cambridge examinations, and for the Primary, F.R.C.S., are held throughout the year.

A register of approved lodgings is kept by the medical secretary, who has a list of local medical practitioners, and others who receive students into their houses.

The prospectus of the school containing full particulars as to fees, course of study advised, &c., and all necessary information will be given on application to Mr. Rendle, the medical secretary.

UNIVERSITY COLLEGE HOSPITAL.—This hospital is situated in Gower Street, not far from Euston Railway terminus. The college where the classes are held faces the hospital, on the opposite side of the street. The number of beds available for teaching purposes is 210.

Appointments.—Eight house physicians, six house surgeons, four senior and four junior obstetric assistants, and two ophthalmic assistants, are selected annually by examination from among the senior students, without fee. The house physicians and house surgeons reside in the hospital for a period of six months, and the senior obstetric assistants for three months, and receive their board and lodging free.

The offices of out-patient physicians' and surgeons' assistants, clinical clerks, surgeons' dressers, and ophthalmic surgeons' assistants are filled by pupils who are also students of the college, without additional fee.

Scholarships, &c.—Entrance Scholarships: One of the value of £120, and two of 55 guineas for proficiency in science, the subjects being those of the Preliminary Scientific Examination of the University of London, and two of 76 guineas each, the subjects being Anatomy and Physiology; the Atkinson-Morley surgical scholarship of £45 a year, tenable for three years; Atchison's scholarship, value £55, tenable for two years; Sharpey physiological scholarship, value about £110 a year, tenable for three years; Filliter exhibition for proficiency in pathological anatomy, value £30; Erichsen prize, operating case, value £10 10s., awarded for practical surgery. Dr. Fellow's clinical medals, the Liston gold medal, Alexander Bruce gold medal, Cluff memorial prize, Tuke medals for pathology class medals, &c.; gold and silver medals, or other prizes as well as certificates of honour, are awarded after competitive examinations in particular branches of study. The Tuffnell scholarship of £100 for chemistry, two years; and the Clothworkers' exhibitions in chemistry and physics of £30 each, can also be held in the medical faculty.

Fees.—The following have been grouped to meet the requirements of the various examining boards:—1. For the medical examination required by the Examining Board in England and the Society of Apothecaries (exclusive of instruction in vaccination and attendance at a fever hospital): 135 gs., if paid in one sum at the commencement of the course; 140 gs. if paid by instalments, as follows: First year, 65 gs., second year 50 gs., third year 25 gs. 2. For those students who do not require to attend chemistry, pharmacy, and elementary biology at a medical school (under the regulations of the examining board in England) the fee is: 117 gs. if paid in one sum; 122 gs. if paid by instalments, as follows: First year 55 gs., second year 40 gs., third years 27 gs. 3. For the courses necessary for the preliminary scientific examinations of the University of London, 35 gs. 4. For the course of instruction for the intermediate examination in Medicine of the University of London, 55 gs. paid in one sum. 5. For the course of instruction for the final M.B. examination of the University of London, 76 gs. if paid in one sum; 78 gs. if paid by instalments, as follows: First year 45 gs.; second year 33 gs. This course of instruction is also suitable for the corresponding examinations at the Universities of Oxford, Cambridge, and Durham. 6. Composition fee for dental students, for the courses required for the L.D.S., 65 gs., or exclusive of chemistry, practical chemistry, physics, and materia medica, 50 gs. The composition fees, 1, 2, 4, and 5, admit to attendance on systematic lectures and to hospital practice, where this is included in the fee, during five years.

WESTMINSTER HOSPITAL.—This hospital is conveniently situated, facing the Abbey, and is readily accessible from all parts of the metropolis. It contains 205 beds for general cases, and all the special departments. New school buildings have been erected close by which afford accommodation for 150 students. The class rooms, dissecting rooms, and lecture theatre are excellent samples of modern erections, affording ample scope for study.

Appointments.—Curator and pathologist, receiving respectively £40 and £50 per annum; medical and surgical registrars, each £40; two house physicians, two house surgeons, two assistant house surgeons, and resident obstetric assistant. These officers, except the four first named, are all boarded free of expense. Fourth year's students are appointed to be clinical assistants in the various departments.

Scholarships, &c.—(a) Winter Session.—The Guthrie Scholarship £60, entrance scholarship £40, entrance scholarship £30, colonial scholarship £60, colonial scholarship £40, dental scholarship £20; subjects, Latin, mathematics, experimental physics, chemistry, and either Greek, French, or German. Oxford and Cambridge Scholarships, £40, subject—anatomy and physiology, Natural science scholarship, £60, same as for Prel. Sci. of University of London. Natural science scholarship, £40, chemistry and physics. Free presentation, open to

pupils of Epsom Medical College. (b) Summer Session.—Natural science scholarship, £60, same as winter. Natural science scholarship, £40, same as above. Arts scholarship £50, arts scholarship £50, colonial scholarship £60, colonial scholarship £40, Oxford and Cambridge scholarship £40, subjects same as in winter session. (c) Prizes.—Treasurer's, 10 guineas, for first year's men; President's, 20 guineas, for second year's men; Chadwick, 20 guineas, for students of any year not exceeding fifth; Fish, £20, for proficiency in pathology. To be competed for by unqualified men. Bird medal and prize, £14, for students who have completed fourth winter session. Sturges prize in clinical medicine £8, clinical surgery prize £5, to be competed for by unqualified men. And class prizes in the various subjects.

Fees.—In one payment of 110 guineas, or two payments of 60 guineas each, payable on entrance, and at the commencement of second year respectively, or by six payments distributed over six sessions of 25 guineas and 20 guineas alternately. Fees for shorter periods or for single courses may be learned on application to the Dean. Fees for dental students, payable in one sum on entrance, 50 guineas, or in two instalments of £27 10s.

LONDON (ROYAL FREE HOSPITAL) SCHOOL OF MEDICINE FOR WOMEN.—This school, which is situated in Hunter Street, Brunswick Square, opens at the same time, and the periods of study, lectures, &c., are similar to those at the ordinary medical schools. A commodious dissecting-room, physiological and chemical laboratories, and library are provided at the School, and clinical lectures are regularly delivered at the Royal Free Hospital, Gray's Inn Road, which institution is appropriated to the students at this School as a field of practical study and experience; clerkships, dresserships, being tenable there without fee by the women.

Scholarships, &c.—Entrance Scholarship of £30. Bostock Scholarship, £60, for two or four years, given on the result of the Preliminary Scientific Examination of the University of London. The John Bryon scholarship of £20 a year for four years, the Stuart Mill scholarship of £30 a year for four years, the Fanny Butler scholarship of £14 10s. a year for four years are offered from time to time. The Mabel Webb Research Scholarship, value £30 for two years, for research work in chemistry, physiology, or pathology. The Helen Prideaux prize of £50 is offered every other year to graduates of the School. Three Evans prizes of £3 3s., £2 2s., and £1 1s. respectively, are given in the midwifery class, and two Durham prizes of £5 and £3 are given in the gynecology class. Two Mackay prizes of £20 each are offered annually. There are other scholarships for ladies willing to qualify themselves as practitioners in India. There is also a small fund from which assistance can occasionally be given to students who specially require pecuniary help.

Fees.—The fee for the ordinary curriculum of non-clinical lectures is £90 if paid in one sum, or £96 if paid in instalments. The fee for clinical teaching is £35, or £40 if paid in instalments.

Classes for the Preliminary Scientific Examination of the University of London will commence in October, 1899. Fee for the whole course, 16 guineas.

Women are eligible for the diplomas of the University of London, the Royal University of Ireland, the University of Durham, the Universities of Edinburgh, Glasgow, Aberdeen, and St. Andrews, the Conjoint Examinations of the Royal Colleges of Physicians and Surgeons, Edinburgh, and Faculty of Physicians and Surgeons, Glasgow, the Royal Colleges of Physicians and Surgeons, Ireland, and the Society of Apothecaries, London, each of which gives a qualification in medicine, surgery, and midwifery.

EXTRA-ACADEMICAL INSTITUTIONS IN LONDON.

COOKE'S MEDICAL SCHOOL.—The school is prepared to admit to its supplementary work all who may wish to join the same, but in regard to its curriculum work it does not receive more than half-a-dozen students in the course of the year, these have special advantages both as regards anatomy and physiology. Charges but slightly in excess of current charges. The Bland Sutton Presenta-

tion—named after Mr. Bland Sutton, F.R.C.S., surgeon to Middlesex Hospital (a former pupil of the school)—confers the privilege of free education during the first two years of medical studies. Particulars forwarded on application. By decision of various examining bodies gentlemen rejected at their anatomical and physiological examinations (second conjoint, &c.) can get signed up for the supplementary work they are required to put in before re-examination. The school is also recognised for the special dissections for the Fellowship of the Royal College of Surgeons. The surgical operations are performed on the dead body, and these courses are recognised for army examinations and the College of Surgeons, &c. The school possesses a good collection of physiological and chemical apparatus, and gentlemen preparing for the higher examinations receive special instruction in the more difficult subjects by separate classes.

LONDON SCHOOL OF DENTAL SURGERY.—This institution is the oldest of the Dental Colleges in the United Kingdom, and its teaching is recognised by the Royal College of Surgeons for the dental diploma. It is centrally situated in Leicester Square, is open daily, and under the supervision of a special staff and house surgeon. The mechanical laboratory is the most perfect of its kind, and its usefulness can hardly be over-estimated. At the present time its accommodation is hardly equal to increasing requirements, and an enlarged building is in contemplation. Four demonstrators have been appointed to instruct the new students in the elements of operative dental surgery, and at the beginning of the session each demonstrator gives a course of lectures on this subject. There is the Saunders Scholarship and Walker Scholarship (entrance) value £20 each, awarded yearly, and the eight house surgeoncies are filled by students of the hospital holding the L.D.S. Fee for two years' hospital practice required by the curriculum including lectures, £50.

NATIONAL DENTAL HOSPITAL.—This institution is situated in North-West London (Great Portland Street) and the same teaching facilities and hospital practice are obtainable here as at the foregoing institution, special demonstrations being given by members of the staff daily. There are also a mechanical laboratory, students' common room, a metallurgical laboratory, extraction and stopping rooms, students' hall, &c., all lighted by electricity, and warmed and ventilated after the most approved requirements; in fact, this institution may be pronounced a model dental hospital and school. The winter session commences at the same time as at the medical schools, on October 3rd. The medical tutors hold special classes before each College examination. The prizes include one entrance exhibition, value £15; and the Rymer prize of £5 5s. The fee for two years' hospital practice required by the curriculum, including lectures, is £40.

UNIVERSITY EXAMINATION POSTAL INSTITUTION.—There is an institution conducted by Mr. E. S. Weymouth, M.A. (27, Southampton Street, Strand, which offers special courses of lessons through the post for the medical examinations of the London University (including the M.D.), and of the Royal Colleges. Also for the Diploma in Public Health of Cambridge or the Royal Colleges. Three of the medical tutors are Gold medallists.

Medical students are admitted to the practice at the following metropolitan hospitals, to which no medical school is attached. Detailed particulars will be supplied on application to the various secretaries.

ROYAL FREE HOSPITAL, Grays' Inn Road.—This hospital contains 170 beds. It is here that the students at the London School of Medicine for Women do their medical, surgical, and clinical work. The clinical clerkships and surgical dresserships are held exclusively by these students. The fees payable are £28 the first, and £16 each succeeding year. The composition fee for all classes and lectures, except clinical, is £80 in one sum, or three payments of £40, £30, and £15.

WEST LONDON HOSPITAL, Hammersmith.—This contains over 100 beds, and has an extensive out-patient department. Dresserships and clinical clerkships may

be obtained. Two house-surgeons and two house-physicians are elected every six months. Special departments have recently been opened for diseases of the throat, ear, skin, and deformities. An electrical department has also been added.

GREAT NORTHERN CENTRAL HOSPITAL, Holloway Road, N.—This institution has been recently enlarged, and now contains 155 beds. The practice of the hospital is open to practitioners and senior students, and clinical assistants are appointed in the wards and out-patient departments, as in the larger general hospitals.

BETHLEHEM HOSPITAL.—This hospital is open for the admission of two recently qualified resident medical assistants who are desirous of acquiring special knowledge regarding the insane. The next election takes place in October at Bridewell Hospital, and the elected candidates will be expected to take up their residence on November 1st.

NATIONAL HOSPITAL FOR EPILEPSY AND OTHER DISEASES OF THE NERVOUS SYSTEM.—Contains 200 beds. It has on its staff men of European reputation, and the Institution is recognised by the Conjoint Board where part of the fifth year of study may be devoted to clinical work. Clinical clerks are appointed to the physicians for out-patients, and courses of lectures and clinical demonstrations are given each year.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.—The largest institution for the treatment of affections of the chest in the United Kingdom, there being 321 beds in the two buildings. There are four house-physicians, who reside in the hospital, each for a period of six months. Lectures and demonstrations are given by members of the medical staff on Wednesdays and Fridays at 4 o'clock, save during the vacations. Pupils are admitted to the practice of the hospital. Terms, £3 3s. for three months; six months, £5 5s.; perpetual, £10 10s.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria Park.—This is a large and well-equipped hospital at the East End, containing 164 beds. Clinical lectures and demonstrations are given by the members of an exceptionally experienced staff. Fee for three months' attendance on hospital practice, 2 guineas; six months, 3 guineas.

CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL, Gray's Inn Road, contains seventeen beds, with an extensive out-patient department recently enlarged. Clinical demonstrations and instruction to qualified practitioners and senior students daily during the hours of the surgeon's visits. Twelve clinical assistants who must be duly qualified are elected to assist the surgeons. Operation days—in-patients, Tuesdays, 2.15 p.m.; out-patients, Fridays, 2 p.m. Fees for the three months' attendance, £3 3s.; six months, £5 5s. Full details of this institution will be found on reference to our advertisement columns.

HOSPITAL FOR DISEASES OF THE THROAT AND CHEST, Golden Square, W., with branches at Newington, Walworth and Notting Hill, contains 50 beds. Students are admitted to hospital practice on payment of fee of three months' course, £3 3s.; for six months, £5 5s.; perpetual, £7 7s.

THE HOSPITAL FOR WOMEN, Soho Square.—The hospital contains 61 beds. In connection with this institution there is now an organised school of gynaecology, open to qualified medical men and to students after their third year. Clinical assistants to the physicians and surgeons in the in-patient and out-patient departments are appointed every three months. Fee for the three months' course, £5 5s.

THE SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN, Lower Seymour Street, W., offers excellent opportunities for clinical study and training in the details of operative gynaecology. The success of the staff in this department have gained for them an European reputation. There are 47 beds.

HOSPITAL FOR SICK CHILDREN, Great Ormond Street, Queen's Square, and Cromwell House, Highgate. Fee for three months' attendance, £3 3s.; perpetual, £5 5s. There are now 244 beds, and it is probably the largest institution of its kind in the world. The practice of the hospital has been thrown open gratuitously to pupils of

the different hospitals and medical schools of London, on conditions to be ascertained from the secretary.

ROYAL LONDON OPHTHALMIC HOSPITAL (formerly in Moorfields, rebuilt during the present year in the City Road), is the largest hospital devoted to this specialty in Great Britain. Students and practitioners are admitted to the practice daily at 9 o'clock. Operations, 10 o'clock and after. Fee for six months, £3 3s.; perpetual, £5 5s. Further particulars of the secretary, Mr. R. J. Bland.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL, King William Street, Charing Cross, has about 30 beds, and a very large out-patient clinique. The lectures and demonstrations are arranged with special reference to the requirements of practitioners and senior students. Fee, six months, £3 3s.; perpetual, £5 5s.

ROYAL EYE HOSPITAL, St. George's Circus, Southwark.—There are 40 beds and 2 cots. Fees £2 2s. for 3 months, £3 3s. for 6 months, and £5 5s. perpetual. Courses are held on ophthalmoscopy, refraction and diseases of the eye; fee £1 1s. for each course, but perpetual students may attend each course once without extra fee. Pathology class, £1 1s. extra to cover cost of materials.

ST. PETER'S HOSPITAL FOR STONE.—This is the only special hospital for the treatment of stone and genito-urinary diseases in the United Kingdom. It contains 26 beds and one private ward, and has an excellent record. Students are admitted on the usual terms.

SEAMEN'S HOSPITAL.—This is situated on the Thames at Greenwich, having bed accommodation for 225 patients, with a branch at the Victoria and Albert Docks containing 23 beds. In connection with this institution there has recently been established a school for the study of tropical diseases, at which opportunities are afforded to students and others who may be desirous of studying diseases incidental to tropical climates, and also practical surgery, before entering the Services or going abroad.

Resident chambers are available for students who must be post-graduates or in the fifth year of their medical studies.

METROPOLITAN HOSPITAL, Kingland.—This was until recently known as the Metropolitan Free Hospital, is situated in the north-eastern district of the metropolis, and contains 160 beds. It is a general hospital, with various special departments for the treatment of diseases of the eye, throat, ear, &c.

SKIN HOSPITALS.—"St. John's Hospital for Diseases of the Skin." Out-patient Department, 49 Leicester Square; In-patient Department, 238 Uxbridge Road. This hospital has now a splendidly-equipped in-patient department, with 50 beds, some of which are entirely isolated from the main part of the building for the reception of contagious cases. One of the oldest institutions of the kind is the Western Skin Hospital, which was started as long ago as 1851. In recent years the number of patients has greatly increased. The practice of the hospital is open to students and practitioners. Students of this specialty have also the "London Skin Hospital," in Fitzroy Square, with seven beds and an out-patient department of over 1,400. There is also the Stamford Street Skin Hospital, in the southern part of the metropolis, with 10 beds and an out-patient department of 5,600, so that students' needs in this direction are well catered for.

PROVINCIAL MEDICAL SCHOOLS.

BIRMINGHAM.—THE MASON UNIVERSITY COLLEGE.—The School of Medicine, formerly in existence at the Queen's College, is now united with the Mason University College under the title of "The Queen's Faculty of Medicine." New buildings have been specially erected for the purpose, and contain large dissecting-rooms, museums, theatres, and all the necessary accessory rooms of a large and well-equipped school. A new bacteriological laboratory has recently been built, capable of accommodating about 75 students, and a Professor appointed to devote the whole of his time to the subject. At the Queen's and General Hospitals, to which students at this college have access, there are 400 beds available for clinical instruction. Students also have admission to the City Lunatic Asylum, the City Fever Hospital, the Eye, Orthopaedic, and Ear and Throat Hospitals. Students are admitted—(1) as matriculated

students who enter for their entire medical education; (2) as occasional students for one or more courses of lectures. There are thirty-five resident appointments in the hospitals of the City, open to students of the School.

Scholarships, Prizes, &c.—Two Ingleby Scholarships for obstetric medicine and surgery and diseases of women. Sydenham, Queen's, and Sands Cox scholarships of £31 10s. Clinical prizes:—Senior medical prize for third and fourth year's students, £5 5s.; Junior medical for first or second year's students, £3 3s. Senior surgical prize for third and fourth year's students, £5 5s.; Junior surgical prize for first and second year's students, £3 3s. Midwifery prize, £4 4s. Examinations are held in the various subjects at the end of each session, and medals and certificates are awarded.

Fees.—College fees for all lectures amount to £70, payable by two equal instalments. There is an entrance fee of £3 3s. Students entering for single courses have to pay entrance fee, £1 1s. for each winter, and 10s. 6d. for each summer session. All students will be required to attend at the Queen's and the General Hospitals as directed by the Clinical Board, excepting students who enter the hospital for six months only. Fees for attendance for four years on the medical and surgical practice, and on the clinical lectures at both hospitals, £42.

Special facilities are offered at Mason University College to medical students for the work of the Preliminary Scientific Examination of the University of London.

The Dental Department, in conjunction with the General, Queen's and Dental Hospitals, affords a complete curriculum for all Dental Diplomas. There is an entrance scholarship value 15 guineas, and medals and honour certificates are awarded in the classes.

BRISTOL UNIVERSITY COLLEGE.—FACULTY OF MEDICINE.—This is the only medical school in the West of England. The lectures and instruction given in the Faculty of Arts and Science of University College, Bristol, are adapted to the various preliminary examinations, and students can complete in Bristol the entire course of study required for the medical and surgical degrees of the University of London and the Royal College of Surgeons of England, and of the Apothecaries' Society of London, and for the examination of the Army and Navy Boards. It is now arranged that students of the college shall be admitted to the clinical practice of the Bristol Royal Infirmary and the Bristol General Hospital conjointly, and consequently both these institutions are open to all students. The infirmary and the hospital comprise between them a total of 470 beds, and both have very extensive out-patient departments. Special departments for the diseases of women and children, and of the eye, ear, and throat, besides large outdoor maternity department and dental departments. Very exceptional facilities are thus offered to students for obtaining a wide and thorough acquaintance with all branches of medical and surgical work.

Appointments.—At the Royal Infirmary, and also at the General Hospital, clinical clerks and dressers reside in the house in weekly rotation. A pathological clerk is appointed every three months.

Clinical lectures are given regularly at both institutions.

Scholarships, Prizes, &c.—Prizes and certificates of honour are given in University College in all the subjects of the curriculum, open only to perpetual students. There are two entrance scholarships, value £50 and £30 respectively, two Martyrs' memorial scholarships (pathology and morbid anatomy) of £10 each, the Tibbit's memorial prize, value £9, for proficiency in practical surgery, one gold and silver medal awarded by the committee, and various prizes for clinical work in surgery and medicine.

Fees.—School fees for attendance on all courses of lectures except comparative anatomy, 65 guineas, or 55 guineas. Clinical fees—Surgical practice, one year, 12 guineas; perpetual, 20 guineas. Medical practice pupil, 20 guineas; perpetual medical and surgery, 35 guineas; clerk or dresser, 5 guineas; obstetric clerk, 3 guineas.

Prospectus and further information on application to the Dean, Professor E. Markham Skerritt.

YORKSHIRE COLLEGE SCHOOL OF MEDICINE, LEEDS.—This school, which was founded sixty-nine years since as the Leeds Medical School, forms the medical department of the Yorkshire College, one of the colleges constituting

the Victoria University. Students of the Yorkshire College are therefore eligible for the degrees of the Victoria University as well as for those of the London, Durham, and Edinburgh Universities, and for the ordinary diplomas. The building erected on a site contiguous to the infirmary, and opened five years ago contains one of the finest dissecting rooms in the kingdom, extensive laboratories for physiology and pathology with the most recent improvements in fittings and apparatus, ample lecture room accommodation, a large library, and separate museums for pathology and anatomy. Professors and lecturers are attached, and the clinical teaching is given by the physicians and surgeons attached to the infirmary. Ophthalmic demonstrations and demonstrations of skin diseases are given in the infirmary by surgeons in each department, where also are obtainable various clinical clerkships, dresserships, and other appointments; and an extern maternity charity is attached, at which the necessary attendance at labours can be taken; besides the infirmary, there are a large dispensary, a large hospital for infectious diseases, and a hospital for women and children, all of which are open to students of the schools.

Students here have also excellent opportunities of acquiring a thorough insight into psychological medicine, as the renowned West Riding Lunatic Asylum is in connection, whereat lectures on mental diseases are delivered during the summer.

Scholarships, Prizes, &c.—(1) A Gilchrist scholarship of £50 a year for three years is awarded annually, and a second biennially, to the candidate who stands highest at the June Preliminary Examination at the Victoria University, provided he passes in the first division. (2) A university scholarship of £50 is awarded annually on the results of the second examination for the degree of M.B. and Ch.B., held in March. (3) An entrance scholarship of 64 guineas (covering composition fee for a full curriculum of lectures) is offered every September to university students. There are also a Hardwick prize in clinical medicine, a Mc Gill prize in clinical surgery, each of the value of £10, and Thorpe prizes of £10 and £5 in forensic medicine and hygiene, besides silver and gold medals and other class prizes. The composition fee for attendance upon all the required courses of school lectures is 64 guineas for university students who have attended the preliminary scientific courses, and the same for non-university students, exclusive of chemistry and biology.

At the General Infirmary, containing 447 beds, the perpetual fee for medical and surgical practice and clinical lectures is £42 in one sum, or two instalments of £22 each. These fees are not included in the composition fees for lectures, and are payable separately.

A scholarship of £42 to cover the cost of medical and surgical practice is also offered annually.

LIVERPOOL UNIVERSITY COLLEGE (VICTORIA UNIVERSITY).—New physiological and pathological laboratories were opened by Lord Lister last October. The college contains ample class-room and laboratory accommodation for study and research in pathology and bacteriology, and provision in the way of laboratories and museums for the study of public health. The museums of anatomy, pathology, materia medica, and public health are furnished with complete provision for the needs of students, and have recently been reorganised and revised.

Royal Infirmary.—The Royal Infirmary which adjoins the school, contains 300 beds, with 40 special beds for the treatment of diseases of women. The Lock, Lying-in, Eye and Ear, Children's, and Dental Hospitals are in the immediate vicinity, and their practice is open to the students of the medical faculty.

Fees.—The composition fee for lectures and classes is £24 15s. for preliminary scientific classes; £80 for the medical classes required for the Victoria University Degree; £70 for classes required for the Diplomas of the Conjoint Boards. Royal Infirmary, £42. All fees, except the first named, are payable in two instalments.

Appointments at the Royal Infirmary.—Three house surgeons, 3 house physicians, and one extern house surgeon are appointed for six months. Three clinical clerks for each physician; three or more dressers for each surgeon,

and two clerks to the Thornton Ward for diseases of Women are appointed every three months. Post-mortem clerks are appointed for six weeks.

Scholarships.—(a) Four Gee Entrance Scholarships are awarded annually of the value of £25. On the results of a special scholarship examination, and numerous class prizes are awarded annually. (b) Two Lyon Jones scholarships, of the value of £21 each, a junior scholarship, open at the end of the first year of study to Victoria University students, in the subjects of the first M.B. examinations; and a senior scholarship open to all students in the school at the end of the third year of study, on the subjects of anatomy, physiology, and materia medica. (c) The Derby exhibition of £15 is awarded in clinical medicine and surgery in alternate years; in 1900 the subject will be clinical surgery. (d) Two Holt fellowships, each of the value of £100, to senior students, for study and research in physiology and pathology. (e) A Robert Gee fellowship in anatomy of the value of £100, for study and research in anatomy. (f) An Alexander fellowship of £100 a year is offered for research in pathology. (g) The Torr gold medal in anatomy and the Holt medal in physiology.

School of Dental Surgery.—There is a School of Dental Surgery in connection with the medical faculty. The curriculum includes lectures and demonstrations on all the subjects required for diplomas in dental surgery. In addition, laboratory courses are conducted in dental histology and dental pathology. Practical instruction in dentistry is given at the Dental Hospital in Mount Pleasant, where an admirable operating room and a new mechanical laboratory have recently been constructed.

Fees.—A payment of £50 on entrance, or in two equal instalments, entitles the student to attendance on all lectures and demonstrations (medical and special) required for the dental licence of the College of Surgeons. The fee for two winters' surgical practice is £10 10s., and for two years' dental hospital practice, £21.

A limited number of apprentices are taken at the hospital, fee, £105.

Scholarships.—(a) A Fletcher scholarship of the value of £20 is awarded for excellence in Dental Mechanics to students beginning their course. (b) A scholarship in Dental Surgery (value £10 10s.) is awarded as the results of examinations in general and dental surgery. (c) Quinby prizes (of the value of £20 altogether) for operative dentistry. (d) A prize (value £5 5s.) for Dental Mechanics. (e) Ash's prizes (value £2 2s.) for an essay on some subject in Dental Surgery. (f) Medical faculty prizes, medals, and certificates.

School of Pharmacy.—A department of Pharmacy has been instituted, comprising the necessary courses for the minor and major examinations of the Pharmaceutical Society, in chemistry, physics, botany, materia medica, and pharmacy. The composition fee is £17, and the classes may be attended in one or two years.

MANCHESTER.—VICTORIA UNIVERSITY, OWENS COLLEGE SCHOOL OF MEDICINE.—The medical school buildings, which include large laboratories, dissecting-rooms, library and reading rooms, are on the most modern principles, and students wishing to engage in anatomical, physiological, or pathological research will find excellent opportunity for study in the complete and well furnished laboratories. The buildings were extended only a few years ago, but owing to the rapid growth of the school further large additions have been made, including lecture theatres and laboratories. Hospital practice is taken out at the Royal Infirmary, which contains 300 beds. The Cheadle Lunatic Asylum, St. Mary's Hospital, the Southern Hospital, and other special hospital also afford teaching facilities of great importance.

Appointments.—The following appointments are made in connection with the Manchester Royal Infirmary; Surgical Registrar, at £80 per annum; a Pathological Registrar, at £100 per annum; a Medical Registrar, at £70 per annum; two Assistant Medical Officers, each at £80 per annum; a Resident Medical Officer at the Convalescent Hospital, Cheadle, one year, £150 per annum; Resident Medical Officer, one year, £150; Resident Surgical Officer, one year, £150 per annum; two Chloroformists, annually, at £50; two House Surgeons and one House Physician are appointed every three months for

a term of six months; a Resident Assistant at the Convalescent Hospital, Cheadle, appointed every six months.

Scholarships.—Dalton Entrance Scholarship, £40 per annum for two years; Cartwright Entrance Scholarship, £35 per annum for three years; Hulme Entrance Scholarship, £35 per annum for three years; Rogers Entrance Scholarship, £40 per annum for two years; Seaton Entrance Scholarship, £40 per annum for two years; James Gaskill Entrance Scholarship, £40 per annum for two years; Kay Shuttleworth (Sir Jas. Philips) Scholarship, £30 per annum for three years; Theodores Modern Languages Exhibition, £15; Honorary Research Fellowships; Manchester Grammar School Scholarship, £18 per annum for three years; Turner Scholarship of £20 to students who have completed four years of study in the College; Platt Physiological Scholarship, value £50, tenable for two years, open to students between the ages of 18 and 25; two Platt exhibitions, £15 each, for first and second year's students in physiology; Sidney Renshaw Physiological Exhibition, £15; Dumville Surgical Prize, £15, at the end of the winter session; two Dauntsey Medical Entrance Scholarships, value £35, tenable for one year; John Henry Agnew Scholarship in Diseases of Children, value about £30 awarded annually; Gilchrist Scholarships of £50 per annum, tenable for three years in any of the Colleges of the Victoria University, awarded annually to the candidate gaining the highest number of marks in the first division of the Preliminary Examination of the Victoria University; the Bradley Memorial Scholarship, £20, in Clinical Surgery is offered annually in the summer session to candidates who must be fourth year students; one Medical and one Surgical Clinical Prize are also offered annually.

Fees.—Composition fee, £70, in two sums of £35 each, Hospital practice: composition fee, £40, or two instalments of £25 each.

Dental Fees.—Composition fee, £50, payable in two sums of £25 each. Hospital practice, £21.

SHEFFIELD UNIVERSITY COLLEGE, MEDICAL DEPARTMENT.—The Sheffield School of Medicine has been incorporated by Royal Charter with Firth College and the Technical School to form the "University College, Sheffield." The new medical school was opened in 1888. It contains a medical library, good class-rooms, an excellent anatomical department, and every provision for medical education under the most modern principles. Last year the physiological department was entirely reconstructed and equipped, in memory of the late president of the school, Mr. Wm. F. Favell, through the generosity of anonymous donors. The department consists of a lecture and demonstration theatre, students' laboratory, preparing room and galvanometer room. Each student has his own laboratory bench, with gas, water, electric light, and all the requisite apparatus. New premises have been acquired near the College for the pathological museum and laboratory, and also for a bacteriological laboratory, which has been completely equipped through the generosity of "A Sheffield Citizen." The course of lectures and instruction is adapted to meet the requirements of the various examining bodies. Students at this college obtain medical and surgical practice at the Royal Infirmary, a well-appointed institution, containing 240 beds, and also at the Sheffield Royal Hospital, containing 125 beds. The fees for attendance, £8 6s. each for medical and surgical practice during the winter session, and for three months £3 3s. each. Perpetual fee for medical and surgical hospital practice in a single payment of £45, or in two payments, viz., £26 on entrance, and £22 within twelve months afterwards. Students are also admitted to the practice of the Jessop Hospital for Diseases of Women, to the City Fever Hospitals, and to the South Yorkshire Lunatic Asylum at Wadsley. Some of the lecturers and other local members of the profession receive house pupils, assisting them in their studies where such arrangements are desirable. The winter session will commence on October 2nd. Dean, Dr. W. T. Cocking, to whom applications may be addressed.

Scholarships, &c.—An entrance scholarship of the value of £110 is annually awarded to the best candidate (if of

sufficient merit) in mathematics, elementary physics, inorganic chemistry, Latin, English.

Composition fee, 60 guineas, or in two instalments of 35 guineas and 30 guineas for lectures and practical classes required by the Examining Board in England.

Prizes for clinical medicine and clinical surgery of 10 guineas; prizes in books and certificates awarded annually.

UNIVERSITY OF DURHAM COLLEGE OF MEDICINE, Newcastle-upon-Tyne.—A very commodious and ornate new building has been erected here at a cost of about £31,000. The electric light has been installed throughout the whole of the working part of the college. The Royal Infirmary, at which clinical instruction is obtained, contains 280 beds. Pathological demonstrations are given as opportunity offers. Practical midwifery can be studied at the Newcastle Lying-in Hospital. Opportunities for practical study are also afforded by the Dispensary, City Infectious Diseases Hospital, Eye Infirmary, Children's Hospital and Northumberland County Lunatic Asylum. Lectures are given on psychological medicine and public health.

Appointments.—Assistant demonstrators of anatomy receiving each an honorarium; prosectors for the professor of anatomy, assistant demonstrators of physiology and pathology, assistants to the dental surgeons, clinical clerks, and dressers are appointed at regular intervals. One year attendance at the College is required on the part of candidates for the degrees in medicine of the University of Durham.

Scholarships, &c.—University scholarships, value £100, for proficiency in arts, awarded annually at the beginning of winter session to full students in their first year only. The Dickinson memorial scholarship (value: the interest of £400 with a gold medal) for medicine, surgery, midwifery, and pathology, open to full students, who have passed the primary examination of a licensing body. The Tulloch scholarship, interest of £400 annually, for anatomy, physiology, and chemistry. The Charlton memorial scholarship, interest of £700 annually, open to full students entered for the class of medicine at end of the fourth or fifth winter. The Gibbs scholarship, interest of £500 annually, for pathology, at end of summer session. Goyder memorial scholarship in clinical medicine and clinical surgery, proceeds of £325 annually. The Luke Armstrong memorial scholarship, interest on £680. The Stephen Scott scholarship in surgery, interest on £1,000. The Heath scholarship in surgery, the next award will be in 1900: the interest on £4,000 is awarded every second year. The Gibson prize in midwifery and diseases of women and children; the interest on £225 is awarded yearly. At the end of each session a prize of books and honours certificates are awarded in each of the regular classes.

Fees.—a) A composition ticket for lectures at the college may be obtained—1. By payment of 70 guineas on entrance. 2. By payment of 45 guineas at the commencement of the first sessional year and 35 guineas at the commencement of the second sessional year. 3. By three annual instalments of 35, 30, and 20 guineas respectively at the commencement of the sessional year. (b) Fees for attendance on hospital practice: For three months' medical and hospital practice, 5 guineas; for six months, 8 guineas; for one year, 12 guineas; perpetual, 25 guineas; or by three instalments at the commencement of the sessional year, viz., first year, 12 guineas; second year, 10 guineas; third year, 6 guineas; or by two instalments, viz., first year, 14 guineas; second year, 12 guineas.

UNIVERSITY COLLEGE, CARDIFF, SCHOOL OF MEDICINE.—The winter session commences on Monday, October 2nd. The annual address to students will be given on the evening of October 6th by Professor A. W. Hughes, of King's College, London.

The courses of study are recognised as qualifying for the preliminary scientific examination and the intermediate examination in medicine in the University of London, and for the corresponding examinations in the Universities of Edinburgh, Glasgow, St. Andrews, Aberdeen, and Durham, in Victoria University, and in the Royal University of Ireland. Students who are preparing for these examinations may compound for their

courses by paying a fee of £57 10s., while a composition fee of £40 includes all the courses necessary for the first and second examinations of the conjoint board or for those of the Society of Apothecaries, London. In all cases these composition fees may be paid by instalments.

Particulars regarding the staff of the school and the various courses will be found in our advertisement columns.

Scholarships, &c.—The attention of students about to matriculate is drawn to the numerous entrance scholarships and exhibitions which are offered at this college for competition during the present month, most of which may be held by medical students. Full particulars of the examination for these may be obtained from the Registrar.

The college is furnished with all modern requirements for teaching and for laboratory work, whilst hospital instruction is given at the Cardiff Infirmary which is within five minutes' walk of the college. The institution contains 200 beds and has a large out-patient department as well as special departments for the eye, ear and throat.

During the last year it has been found necessary to considerably extend the Chemical Laboratory and a new lecture theatre for the physical department has also been built.

LIVERPOOL ROYAL SOUTHERN HOSPITAL.—The clinical school of this hospital is situated within convenient distance of the School of Medicine, and affords every facility for clinical and pathological study. The hospital contains 200 beds, and, in addition, to the general medical and surgical cases, attention is devoted to the diseases of women and children. The medical and surgical staff visit the wards daily, and the ward instruction is supplemented by weekly clinical lectures. Additions have been made to the teaching staff, so that students may now obtain instruction in diseases of the eye, ear, and throat. The medical and surgical tutors attend every day to instruct the junior students in the methods of diagnosis, and to prepare the senior men for their final examinations. There is an excellent pathological department, with laboratory attached, where demonstrations are arranged for, and regular instruction is given in practical pathology. The practice of St. George's Hospital for Diseases of the Skin is free to students. Ample opportunity is afforded for acquiring a knowledge of dermatology. Recently a bacteriological laboratory has been added where students can obtain a practical knowledge in bacteriology. In connection with the hospital a course of instruction for gentlemen desirous of obtaining a diploma in public health is given, and with this object a chemical and bacteriological laboratory under Mr. Herbert Davies, M.A., Camb., B.Sc., and Dr. Hugh R. Jones, M.A., M.D., B.Sc. (Lond.) has been opened. In addition to the clinical clerkships which are allotted to the students the resident post of ambulance officer is given to the student whom the board may think most suited to hold it every three months. A prize of £20 is annually competed for which affords special advantages for clinical and pathological researches to the holder, and three prizes of £5 each are also awarded to the gentlemen who present the best taken series of medical and surgical cases. Fees.—Perpetual, £28 5s.; one year, £10 10s.; six months, £7 7s.; three months, £4 4s. There are rooms for a limited number of resident students; terms exclusive of fee for hospital practice), £15 15s. per quarter. The practice of the hospital is recognised by all examining bodies.

BRISTOL ROYAL INFIRMARY.—This is one of the largest provincial hospitals in Great Britain, and contains 270 beds. It is provided with all the necessary appliances for a complete clinical education. The resident appointments are five in number, the two juniors of which are each tenable for six months, and are intended for qualified students of the infirmary who have previously acted as medical and surgical registrars. Several scholarships and prizes are obtainable. Fees for admission to the medical practice, six months, 7 guineas; twelve months, 12 guineas; perpetual, 20 guineas. The same fees are payable for surgical practice. Perpetual

fee for medical and surgical practice, 35 guineas. Dental practice, one year, £7 7s.; perpetual, £12 12s.

The following are the principal provincial hospitals to which students are admitted where clinical instruction can be obtained, but to which there is no medical school attached:—

BATH ROYAL UNITED HOSPITAL.—This is a well-appointed hospital in the West of England, with 120 beds, at which students can obtain clinical instruction. The hospital is recognised by the Colleges, and is licensed for dissection. It contains also an excellent museum and library. Fee for six months' attendance, five guineas; twelve months', ten guineas.

BRADFORD INFIRMARY.—The hospital contains 210 beds. Non-resident pupils are received—and abundance of clinical material is obtainable. One year's attendance is recognised by the Examining Boards. Fee, perpetual, £10 10s.

BRIGHTON SUSSEX COUNTY HOSPITAL contains 173 beds. It is recognised by the College of Surgeons and by the Conjoint Board. Out-pupils are admitted to the clinical teaching and the classes at a fee of £21 for two years.

NORFOLK AND NORWICH HOSPITAL.—This hospital is recognised by the Colleges, and contains 220 beds. Fees, £10 10s. for six months', £15 15s. for twelve months' medical and surgical practice. Pupils, resident and non-resident, are admitted.

WOLVERHAMPTON GENERAL HOSPITAL.—The hospital contains 230 beds, attendance at this hospital being recognised by all the Examining Boards. Pupils are trained in clinical work by the medical and surgical staff. Fees.—Six months, £6 6s.; twelve months, £12 12s.; perpetual, £21.

THE ENGLISH UNIVERSITIES.

The English Universities are five in number—viz., Oxford, Cambridge, London, the Victoria, and Durham. Each of these "turns out" a due proportion of medical graduates every year. Those students who have means at command will probably elect to enter at either Oxford or Cambridge, where, perhaps, the social advantages arising from residence at the ancient seats of learning form the chief attraction. Of the University of London we have already spoken, and the Victoria University comprises Owens College, Manchester; University College, Liverpool; and the Yorkshire College, Leeds. With regard to Durham University, great facilities have within the past few years been provided in the matter of medical degrees.

OXFORD.

There are two degrees in medicine, M.B. and M.D., and two degrees in surgery, B.Ch. and M.Ch. The M.B. and B.Ch. degrees are granted to those members of the University who have passed the second examination. Graduates in Arts, B.A. or M.A., are alone eligible for these two degrees. In order to obtain the degrees of M.B. and B.Ch., the following examinations must be passed:—1. Preliminary subjects: Mechanics and physics, chemistry, animal morphology and botany. 2. Professional (a) First Examination: Subjects—Organic chemistry, unless the candidate has obtained a first or second class in chemistry in the Natural Science School; Human physiology, unless he has obtained a first or second class in animal physiology in the Natural Science School; Human anatomy, and *Materia medica* with Pharmacy. (b) Second Examination: Subjects—Medicine, Surgery, Midwifery, Pathology, Forensic medicine with Hygiene. The approximate dates of the examinations are as follows:—Preliminaries—Mechanics, physics, and chemistry, December and June; Animal morphology and botany, December and March; Professional (First and Second M.B.), June and December.

The degree of M.D. is granted to Bachelors of Medicine of the University—(1) who took the degree of M.B. previously to the end of Trinity Term, 1886, provided they have spent three years in the practice of medicine after taking that degree, and have composed a disserta-

tion on some medical subject approved by the Regius Professor of Medicine, before whom it must be read in public; (2) who took the degree of M.B. subsequently to the end of Trinity Term, 1886, provided they have entered their thirty-ninth term and have composed on some medical subject a dissertation which is approved by the professors in the Faculty of Medicine and examiners for the degree of M.B. whose subject is dealt with. A book published within two years of the candidate's application for the degree may be substituted for a dissertation. The degree of M.Ch. is granted to Bachelors of Surgery of the University who have entered their twenty-seventh term, who are members of the surgical staff of a recognised hospital, or have acted as dresser or house surgeon in such a hospital for six months, and who have passed an examination in surgery, surgical anatomy, and surgical operations. This examination is held annually, in June, at the end of the Second M.B. Examination.

The First Examination for the degrees of M.B. and B.Ch. may be passed as soon as the Preliminary Scientific Examinations have been completed. The subjects of this examination may be presented separately or in any combination or in any order, provided anatomy and physiology be passed together.

The Second Examination may be passed after the completion of the first. The subjects of medicine, surgery, and midwifery must be passed at the same examination, but candidates are allowed to offer pathology at a previous examination. Before admission to the second examination candidates must present certificates of instruction in infectious and mental diseases, and of attendance on labours, and of proficiency in the practice of vaccination.

Diploma in Public Health.—An examination is held yearly in Michaelmas Term, open to all registered medical practitioners. No one is admitted as a candidate unless his name has been on the *Medical Register* for twelve months, and unless he has spent after registration a period of at least six months studying in a public health laboratory, and not less than six months studying under the medical officer of health of a county or town containing at least 50,000 inhabitants, or has himself held the position of medical officer of health of a county or urban district of more than 20,000 inhabitants.

Scholarships, &c.—Scholarships in some branch of Natural Science (chemistry, physics, biology) of the average value of £80 per annum, tenable for four years and renewable under certain conditions for a fifth year, as well as exhibitions of a less annual value, are awarded after competitive examination every year by some of the Colleges. Notices of vacancy, &c., are published in the *University Gazette*. In February there is competed for annually, by those who, having obtained a first-class in any school (moderations or final), or a scholarship or prize open to general competition in the University, have passed all the examinations for the degree of B.A., one Radcliffe Travelling Fellowship. It is tenable for three years, and is of the annual value of £200. The examination is partly scientific, partly medical. The holder must travel abroad for the purpose of medical study. A Rolleston Memorial prize is awarded once in two years to members of the Universities of Oxford and Cambridge of not more than ten years' standing for an original research in some biological subject including physiology or pathology.

More detailed information may be obtained from the University Calendar; from the Examination Statutes, 1894, which contain the official schedules of the several subjects of examination in both Arts and Medicine; from the Student's Handbook to the University; from the Regius Professor of Medicine; and from the Professors in the several departments of science.

CAMBRIDGE.

At the University of Cambridge five years of medical study are required for the M.B. and B.C. degrees. The candidate must have resided nine terms (three years) in the university, and have passed the "previous" examination in classics and mathematics. There are three examinations for these degrees. The first is in chemistry, physics, and biology; the second in human

anatomy, physiology, and pharmaceutical chemistry; and the third, in the usual practical subjects with hygiene and pathology, each examination is divided into two parts, which can be taken separately. Subsequently to the third examination an Act has to be kept, which consists in reading an original thesis, followed by an oral examination on the subject of the thesis. As the subjects for the examination for the degree in Surgery are included in the third examination for the M.B. degree, candidates are admitted to the degree of Bachelor of Surgery on passing the third examination for Bachelor of Medicine.

The M.D. degree may be taken three years after the M.B. An Act has to be kept, with oral examinations, and an essay has to be written extempore. There is also the degree of Master of Surgery, for which the candidate, having already passed for B.C., or being M.A. has otherwise qualified in surgery, has to pursue extra study in Surgery, and pass a special examination or submit original contributions of merit to the science or art of surgery. The yearly expenditure of a student who keeps his term by residence in a college is from £150 to £200 a year. This, however, may include all payments to the University and the College—all fees, as well as clothes, pocket money, travelling expenses, &c. Non-collegiate students have only to pay the University fees, which are not large. They lodge and board as they like; their expenses, therefore, are entirely in their own hands.

The University degree grants a diploma in Public Health without the necessity of residence, the examination being in so much of State Medicine as is comprised in the functions of officers of health, and subject to the latest requirements of the General Medical Council in this respect. These examinations are held in Cambridge the first week in April and October. Candidates, whose names must be on the *Medical Register* of the United Kingdom, and need not be members of the University, should send in their applications to the Secretary of the State Medicine Syndicate a fortnight in advance. Every candidate who has passed both parts of the examination to the satisfaction of the examiners will receive a testimonial testifying to his competent knowledge of the subjects comprised in the duties of a medical officer of health. Candidates who desire to present themselves for examination in October next must send in their applications, and transmit the fees (£6 6s. for each part) to the Registry, University of Cambridge, on or before September 25th.

An abstract of the Regulations and Schedules of the range of the examinations in chemistry, physics, biology, and pharmaceutical chemistry, may be obtained upon sending a stamped directed envelope to the Assistant Registry, Cambridge. Full information is contained in the Cambridge University Calendar.

UNIVERSITY OF LONDON.

The Matriculation Examination.—Candidates for any degree in this university must have passed the matriculation examination. It is held twice in each year—on the second Monday in January, and the second Monday in June; and may be held not only at the University of London, but also, under special arrangement, in other parts of the United Kingdom or in the colonies.

The Preliminary Scientific M.B. Examination.—Professional studies pursued before the whole of this examination has been passed will not count towards the course required for the M.B. degree. The examination takes place twice in each year, once for Pass and Honours, commencing on the third Monday in July, and once for Pass candidates only, commencing on the third Monday in January.

Intermediate Examination.—The Intermediate Examination in Medicine takes place twice in each year—once for Pass and Honours, commencing on the second Monday in July, and once for Pass candidates only, commencing on the third Monday in January. The subjects of the examination are anatomy, physiology and histology, organic chemistry, materia medica, and pharmaceutical chemistry. No candidate shall be admitted to this examination unless he is nineteen years of age and has passed the Preliminary Scientific Examination at

least two years previously. Fee for this examination, £5.

4. *M.B. Examination.*—This examination is held for Pass and Honours in October, and for Pass only in May. The candidate must have passed the Intermediate Examination at least twenty-one months earlier, must have attended lectures and hospital practice in a recognised medical school for two years, including at least two months' attendance, each on lunacy and infectious diseases, one of which must be subsequent to the Intermediate Examination, must have conducted at least twenty labours, and have acquired proficiency in vaccination. After having attended Medical and Surgical Hospital practice for at least twelve months subsequent to passing the Intermediate Examination in Medicine, the student is required to attend to Practical Medicine, Surgery, or Obstetric Medicine, with special charge of patients in a Hospital, Infirmary, Dispensary, or Parochial Union during six months, such attendance not to count as part of the Surgical or Medical Hospital Practice already referred to. The examination, which is conducted by written papers, *viva voce*, and by practical examinations, comprises the following subjects:—Pathology, Therapeutics, Hygiene, Surgery, Medicine, Obstetric Medicine, and Forensic Medicine. The candidate must pass in all the subjects. Honours may be taken in Medicine, Obstetric Medicine, and Forensic Medicine.

Bachelor of Surgery.—The examination for the degree of Bachelor of Surgery takes place once in each year, in December. Candidates must produce certificates to the following effect:—1. Of having passed the examination for the degree of Bachelor of Medicine in this University. 2. Of having attended a course of instruction, in operative surgery, and of having operated on the dead subject. The subjects of the examination are surgery (including operations on the dead body), pathology and surgical anatomy. Fee, £5.

Master in Surgery.—The examination for the degree of Master in Surgery takes place once in each year, in December. Candidates must be Bachelors of Surgery of at least two years' standing; one year is, however, remitted in the case of candidates who passed the B.S. examination in the first division. The examination comprises Mental Physiology, Surgery, and Surgical Anatomy.

Degree of Doctor of M.D.—Doctor of Medicine.—The degree of Doctor of Medicine is granted after examination to Bachelors of Medicine of at least two years' standing. The examination comprises mental physiology and medicine, and is conducted by written papers, clinical examination, and *viva voce*. A candidate who presents a thesis approved by the examiners is excused the written examination.

Doctor of Medicine in State Medicine.—This degree is granted to Bachelors of Medicine after examination on producing evidence of having been engaged in the study of State Medicine for at least two years. The examination is the same as for the ordinary M.D., with the exception that State Medicine takes the place of medicine.

Prizes: 1.—The Sherbrooke Prize is awarded triennially for the best essay, embodying original research in some branch of science.

2.—The Granville Prize is awarded in each of the two years intervening between the several awards of the Sherbrooke Prize.

UNIVERSITY OF DURHAM.

One diploma and six degrees in Medicine and Hygiene are conferred:—viz., the degrees of Bachelor in Medicine, Bachelor in Surgery, Master in Surgery, Doctor in Medicine, Bachelor in Hygiene, and Doctor in Hygiene, and Diploma in Public Health. These degrees are open to both men and women.

For the degree of Bachelor in Medicine (M.B.) there are four professional examinations. The subjects for the first are—Elementary Anatomy and Elementary Biology, Chemistry, and Physics. For the second—Anatomy, Physiology, Materia Medica, Therapeutics, and Pharmacology. For the third—Pathology, Medical Jurisprudence, Public Health, and Elementary Bacteriology; and for the fourth—Medicine, Clinical Medicine, and

Physiological Medicine, Surgery and Clinical Surgery, Midwifery and Diseases of Women and Children.

It is required that one of the five years of professional education shall be spent in attendance at the University College of Medicine, Newcastle-upon-Tyne. Candidates for the First Examination who have passed the First Examination of the Conjoint Board in England, and candidates who hold a qualification from a recognised Licensing Body in the United Kingdom, will be exempt from the First Examination of the University, except in the subject of Chemistry with Physics. [N.B.—This regulation will not apply to candidates who commenced their medical studies on or after October 1st, 1896.] Candidates who have passed the First and Second Examinations of the University will be exempt from the First and Second Examinations of the Conjoint Board.

For the degree of Bachelor in Surgery (B.S.) every candidate must have passed the examination for the degree of Bachelor of Medicine of the University of Durham, and must have attended one course of lectures on Operative Surgery, and one course on Regional Anatomy. Candidates will be required to perform operations on the dead body, and to give proof of practical knowledge of the use of surgical instruments and appliances.

For the degree of Master in Surgery (M.S.) candidates must not be less than twenty-four years of age, and must satisfy the University as to their knowledge of Greek. In case they shall not have passed in this subject at the Preliminary Examination in Arts for the M.B. degree, they must present themselves at Durham for examination in it at one of the ordinary examinations held for this purpose before they can proceed to the higher degree of M.S. They must also have obtained the degree of Bachelor in Surgery of the University of Durham, and must have been engaged for at least two years, subsequently to the date of acquirement of the degree of Bachelor in Surgery, in attendance on the practice of a recognised hospital, or in the naval or military service, or in medical or surgical practice.

For the degree of Doctor in Medicine (M.D.) candidates must be of not less than twenty-four years of age, and must satisfy the University as to their knowledge of Greek. In case they shall not have passed in this subject at the Preliminary Examination in Arts for the M.B. degree, they must present themselves at Durham for examination in it at one of the ordinary examinations held for this purpose before they proceed to the higher degree of M.D. They must also have obtained the degree of Bachelor in Medicine of the University of Durham, and must have been engaged for at least two years, subsequently to the date of acquirement of the degree of Bachelor of Medicine, in attendance on the practice of a recognised hospital or in the military or naval services, or in medical and surgical practice.

Each candidate must write an essay, based on original research or observation, on some medical subject selected by himself, and approved of by the Professor of Medicine, and must pass an examination thereon, and must be prepared to answer questions on the other subjects of his curriculum so far as they are related to the subjects of the essay.

For regulations for degrees in Hygiene and for the diploma in Public Health see Calendar for 1899-1900.

Candidates for any of the above degrees must give at least twenty-eight days' notice to the Secretary of the College of Medicine, Newcastle-on-Tyne.

Residence can be had in separate hostels for male and female students at moderate inclusive fees for board, &c., particulars of which and any other college information will be given on application to Prof. Howden, Secretary, University of Durham College of Medicine, Newcastle-on-Tyne.

VICTORIA UNIVERSITY.

Colleges of the University: Owens College, Manchester; University College, Liverpool; and Yorkshire College, Leeds. Candidates for degrees in medicine and surgery must attend, during at least two years, classes in one of the colleges of the University, and one of these

years must be subsequent to the date of passing the First Examination.

The degrees in the Faculty of Medicine are Bachelor of Medicine (M.B.), Bachelor of Surgery (Ch.B.), Doctor of Medicine (M.D.), and Master of Surgery (Ch.M.). All candidates for degrees in medicine and surgery are required to pass the Entrance Examination in Arts, or to have passed such other examination as may from time to time be recognised for this purpose by the University.

The subjects of the Entrance Examination in Arts are—1, Latin; 2, Elementary Mathematics; 3, Elementary Mechanics; 4, English; 5, one of the following:—(a) French; (b) German; (c) Greek; (d) Italian; (e) Spanish; (f) any other modern language, permission to present which has been obtained from the Board of Studies. Notice of intention to present either Italian or Spanish must be given before March 31st in each year.

Before admission to the degrees of Bachelor of Medicine and Surgery candidates are required to send in the usual certificates of age and study as at the other Universities.

All candidates for these degrees must pass three examinations, namely—the First Examination; the Second Examination; and the Final Examination.

First Examination.—The subjects of the examination are—1, Chemistry; 2, Elementary Biology; 3, Physics.

Candidates must have attended, during at least one year, courses of both lectures and laboratory work in each of the above-named subjects.

Second.—1, Anatomy; 2, Physiology (including Physiological Chemistry and Histology); Materia Medica and Pharmacy.

Candidates must have passed the First Examination, and have attended courses of instruction in anatomy (systematic and practical) during two winter sessions and one summer session, in physiology for two winter sessions, in materia medica and pharmacy for one summer session. Candidates may present themselves separately in (a) Anatomy and Physiology; (b) Materia Medica and Pharmacy. Candidates may present themselves in (a) and (b) separately.

Final.—The examination is divided into two parts, which may be passed separately or on the same occasion, but the first part cannot be taken before the end of the third year, and the second part cannot be taken before the end of the fifth year of medical study in accordance with the University regulations. The subjects of examination are as follows:—1, Pharmacology and Therapeutics; 2, General Pathology and Morbid Anatomy; 3, Forensic Medicine and Toxicology and Public Health; 4, Obstetrics and Diseases of Women; 5, Surgery, Systematic, Clinical, and Practical; 6, Medicine, Systematic and Clinical, including Mental Diseases and Diseases of Children. Candidates may select as a first part of the examination two or three of the subjects 1, 2, and 3.

The certificates required from candidates at the Final Examination are practically the same as for the corresponding examination at the London University, and only those who have previously passed the Second Examination are admitted to it. The regulations relating to the M.D. and Ch.M. degrees can be obtained on application to the Registrar.

Fees.—Entrance Examination in Arts £2. First Examination £5; for any subsequent examination £2. The fees for the Second Examination, for the Final Examination, and for the Examination for the degree of Ch.M. are the same as for the First Examination. A fee of £10 is payable on the conferring of the degree of M.D., a fee of £4 on the conferring of the degree of Ch.M.

The Entrance Examination in Arts is held in June, and about the end of September. The first M.B. and Ch.B. is held in June; also about the end of September. The Second and Final Examinations held in March and July, the Examination for Ch.M. in July only.

THE ENGLISH COLLEGES.

The medical corporations in England are the Royal College of Physicians of London, the Royal College of Surgeons of England and the Society of Apothecaries of London. The two Royal Colleges now co-operate to hold a series of examinations, on passing which the

candidate receives the diploma of Licentiate of the Royal College of Physicians (L.R.C.P.), and member of the Royal College of Surgeons (M.R.C.S.). The Society of Apothecaries grants a complete diploma in medicine, surgery, and midwifery.

CONJOINED EXAMINING BOARD IN ENGLAND (ROYAL COLLEGE OF PHYSICIANS OF LONDON AND THE ROYAL COLLEGE OF SURGEONS OF ENGLAND).

Regulations relating to the several Examinations applicable to candidates who commenced their professional education on or after January 1st, 1892.

Any candidate who desires to obtain both the licence of the Royal College of Physicians of London, and the diploma of Member of the Royal College of Surgeons of England, is required to complete five years of professional study at recognised medical schools and hospitals, and to comply with the following regulations and to pass the examinations hereinafter set forth.

Professional Examinations.—There are three examinations, called herein the first examination, the second examination, and the third or final examination, each being partly written, partly oral, and partly practical. These examinations will be held in the months of January, April, July, and October, unless otherwise appointed. Every candidate intending to present himself for examination is required to give notice in writing to Mr. F. G. Hallett, Secretary of the Examining Board, Examination Hall, Victoria Embankment, W.C., fourteen clear days before the day on which the examination commences, transmitting at the same time the required certificates.

The subjects of the first professional examination are—Chemistry and physics, practical pharmacy, and elementary biology. A candidate may take this examination in three parts at different times. A candidate will be admitted to examination in chemistry and physics and elementary biology before registration as a medical student by the General Medical Council, and he may take pharmacy at any time during the curriculum. Rejection entails a delay of not less than three months from the date of rejection, and the candidates will be re-examined in the subject or subjects in which he has been rejected. If referred in chemistry or biology, he must produce evidence of further instruction at a recognised institution. Any candidate who shall produce satisfactory evidence of having passed an examination for a degree in medicine on any of the subjects of this examination conducted at a university in the United Kingdom, India, or in a British colony, will be exempt from examination in those subjects in which he has passed.

The fees for admission to the first examination are as follows: For the whole examination, £10 10s.; for re-examination after rejection in Part I., £3 3s.; and for re-examination in each of the other parts, £2 2s.

The subjects of the second examination are anatomy and physiology. Candidates will be required to pass in both subjects at one and the same time. Candidates will be admissible to the second examination at the expiration of two winter sessions and one summer session (or fifteen months during the ordinary sessions) from the date of registration as medical students and after the lapse of not less than twelve months from the date of passing Parts I. and III. of the first examination.

A candidate referred at the second examination will be required, before being admitted to re-examination, to produce a certificate that he had pursued, to the satisfaction of his teachers, in a recognised place of study, his anatomical and physiological studies during a period of not less than three months subsequently to the date of his reference.

The fees for admission to the second examinations are: £10 10s. for the whole examination, and £6 6s. for re-examination after rejection.

The subjects of the third and final examinations are:—Part I. Medicine, including medical anatomy, pathology, practical pharmacy, therapeutics, forensic medicine, and public health. Candidates who have passed in practical

The diploma of Member of the Royal College of Surgeons of England and the licence of the Royal College of Physicians of London are no longer granted separately except to students who commenced their professional study prior to October 1st, 1884.

pharmacy at the first examination will not be re-examined in that subject at the third examination. Part II. Surgery, including pathology, surgical anatomy, and the use of surgical appliances. Part III. Midwifery and diseases peculiar to women. Candidates may present themselves for examination in midwifery and diseases of women at any time after the completion of the fourth year of professional study, not less than one year after passing the second examination, on production of the required certificates. Candidates may take this examination in three parts at different times, or they may present themselves for the whole examination at one time. They will be required to produce the following evidence before being admitted to any part of the third, or final examination—viz.: In medicine, of having attended lectures on medicine, pathology including bacteriology, pharmacology and therapeutics, forensic medicine, and public health; practical instruction in medicine; medical hospital practice during two winter and two summer sessions; demonstrations in the post-mortem room during twelve months; clinical lectures on medicine during nine months; of having discharged the duties of medical clinical clerk; of having attended practice of a fever hospital and clinical demonstrations at a recognised lunatic asylum: In surgery, of having attended lectures on surgery and pathology including bacteriology; practical instruction in surgery; of having performed operations upon the dead subject; of having attended surgical hospital practice during two winter and two summer sessions; demonstrations in the post-mortem room during twelve months; clinical lectures on surgery during nine months; of having discharged the duties of surgical dresser and having received clinical instruction in ophthalmology: In midwifery, of having attended lectures on midwifery; practical instruction in midwifery; clinical or other lectures, with practical instruction in diseases peculiar to women; and of attendance on 20 labours.

Fees for admission to the third or final examination are as follows:—For the whole examination, £15 15s. Part I. For re-examination in medicine, including medical anatomy, pathology, therapeutics, forensic medicine, and public health, £5 5s.; for re-examination in practical pharmacy (if taken at this examination), £2 2s. Part II. For re-examination in surgery, including pathology, surgical anatomy, and the use of surgical appliances, £5 5s. Part III. For re-examination in midwifery and diseases peculiar to women, £3 3s.

A candidate referred on the third or final examination will not be admitted to re-examination until after the lapse of a period of not less than three months from the date of rejection, and will be required, before being admitted to re-examination, to produce a certificate, in regard to medicine and surgery, of having attended the medical and surgical practice, or the medical or surgical practice, as the case may be, during the period of his reference; and in regard to midwifery and diseases peculiar to women, a certificate of having received subsequently to the date of his reference, not less than three months' instruction in that subject by a recognised teacher.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

Licentiates.—Candidates are now subject to the regulations of the Conjoint Examining Board in England.

Members.—The membership of the college is granted after examination to persons above the age of 25 years who do not engage in trade, do not dispense medicine, and do not practise in partnership.

Medical graduates of a recognised university are admitted to a pass examination, but others must have passed the examinations required for the licence of the college. The examination, which is held in January, April, July, and October, is partly written and partly oral. It is directed to medicine, and is conducted by the president and censors. Candidates under 40, unless they have obtained a degree in arts in a British university, are examined in Latin, and either Greek, French or German. Candidates over 40 are not so examined, and the examination in medicine may in their case be modified under conditions to be ascertained by application to the Registrar. The fee for the membership is £42, but if the candidate is a

licentiate £15 15s. is deducted. In either case £6 6s. is paid for examination.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

Membership.—The candidates are now subject to the regulations of the Conjoint Board.

Fellowship.—The Fellowship of the College of Surgeons is granted after examination to persons at least 25 years of age, who have been engaged in professional studies for six years. There are two examinations—the first in Anatomy and Physiology, which may be passed after the third winter session; the second chiefly directed to Surgery, which may be passed after six years of professional study. The Second Examination may be passed before attaining the age of 25, but the diploma is not granted until the age is reached. Candidates for this part of the examination must have passed the final examination of the Conjoint Board in England, and have been admitted members of the college before they can be admitted thereto.

Fees.—At First Examination: Members, £5 5s.; non-Members, £10 10s.; £5 5s. returned if rejected. At Second Examination: Members, £10 10s.; if not a Member, £21. In the latter case £10 10s. is returned in case of rejection. Further information can be obtained on application to the Secretary of the Royal College of Surgeons, Lincoln's Inn Fields, London, W.C.

SOCIETY OF APOTHECARIES OF LONDON.

Primary Examination.—This examination consists of two parts: Part I.—Elementary Biology, Chemistry, Chemical Physics, including the Elementary Mechanics of Solids and Fluids; Heat, Light, and Electricity; Practical Chemistry and Pharmacy. A synopsis indicating the range of the subjects may be obtained on application. Part II.—Anatomy and Physiology and Histology. A candidate rejected in one or more subjects is not re-examined in the subjects in which he passes. The examination is held in January, April, July, and October.

The Final Examination is held monthly, and is divided into Sections 1 and 2.

Section 1 consists of three parts.

Part I. includes:—Principles and Practice of Surgery, Surgical Pathology, and Surgical Anatomy, Operative Manipulations, Instruments and Appliances.

Part II. includes:—(a) The Principles and Practice of Medicine, including Therapeutics, Pharmacology, Pathology and Morbid Histology. (b) Forensic Medicine, Hygiene, Theory and Practice of Vaccination; and Mental Diseases.

Candidates passing either (a) or (b) will not be re-examined therein.

Part III. includes: Midwifery, Gynaecology, and Diseases of New-born Children. Obstetric Instruments and Appliances. Candidates may enter for Parts I., II., and III. together or separately.

Section 1 of the Final Examination, or any part thereof cannot be passed before the expiration of 45 months from the date of registration as a medical student. During the above period of 45 months not less than 3 winter sessions and 2 summer sessions must have been passed at one or more of the Medical Schools connected with a general hospital recognised by the Society.

Section 2.—This section consists of two parts.

Part I.—Clinical Surgery.

Part II.—Clinical Medicine and Medical Anatomy. Section 2 cannot be passed before the expiration of the fifth year.

Fees.—The fee for examination is £5 5s., total for the licence, £15 15s.; Re-examination—Primary for each Part, £3 3s.; Final, Sec. I., for each Part, £3 3s.; Final, Sec. II., for each Part £3 3s.

Further information, with particulars as to the course of study, and of the certificates required, can be obtained from the Secretary to the Court of Examiners, Apothecaries' Hall, E.C.

The licence is a registrable diploma in Medicine, Surgery, and Midwifery, and qualifies the holder to compete for medical appointments in the Army, Navy, and Indian Services, also for Poor-law, Civil, and Colonial appointments.

Ireland.

QUALIFICATION IN IRELAND.

The Medical Licensing Bodies of Ireland are five in number, and, as a rule, students gravitate into one or other of five classes:—*a.* Those who enter Trinity College, and take a full graduation in arts in addition to their professional degrees. *b.* Those who take the licence of the College of Surgeons with that of the College of Physicians. *c.* Those who take the licence of the Apothecaries' Hall. *d.* Those who take their qualifications at the Royal Irish University, because graduation in arts is not necessary to that institution. *e.* Those who pursue their studies in Ireland, but who migrate to Edinburgh or Glasgow for their licences. Almost all these emigrants come from the Queen's Colleges, and the greater number of them from Belfast, while the Dublin students qualify, as a rule, in Dublin.

We do not attempt to give details as to the requisite courses of instruction for degrees or diplomas, as our epitome must necessarily be insufficient for the information of the student, and we can occupy our available space with information more useful to him.

The Irish Licensing Bodies are as follows:—

THE UNIVERSITY OF DUBLIN,

which grants the degrees of M.B., B.Ch., and B.A.O. to students who have obtained their Arts degree, and the higher degrees of M.D. and M.Ch. to those who have held for at least three years the grade of M.B. and M.Ch. It does not grant degrees to any but full graduates in arts, consequently its degrees hold the highest rank of social and educational qualifications, and are sought for by those who look forward to occupying the best positions in the profession.

The expense of obtaining the degrees of M.B., B.Ch. and B.A.O. is approximately as follows:—Lectures, £89 6s.; Hospitals, £55 13s.; Degree Fees, £27.—£151 19s.

The expense of the B.A. amounting altogether to £83 4s., should be added, making the total cost £235 3s.

Doctor in Medicine.—In addition to its ordinary qualifications, the University grants the following higher degree of M.D.:—Must be M.B., or qualified to take that degree for three years. Total fee for this degree, £13.

Master in Surgery.—Must be a Bachelor in Surgery of three years' standing, and he must then pass an examination in clinical surgery, operative surgery, surgical pathology, surgery, and surgical anatomy (on the dead subject). Fee for the degree of Master in Surgery, £11.

Master in Obstetric Science.—Must have passed the M.B. and B.Ch. examinations, and have completed in addition to the courses for M.B., B.Ch., a course in obstetric medicine and surgery. Fee for the degree of M.A.O., £5.

Diplomate in Medicine, Surgery, and Midwifery.—The course and examination is the same as for the degrees, except that the lectures and examinations in botany and zoology need not have been taken out or passed. Fee for the diplomas in medicine, surgery, and midwifery, £21.

Qualification in State Medicine.—The candidate must be a M.D. of Dublin, Oxford, or Cambridge.

The candidate must have completed, subsequent to registration, six months' practical instruction in a laboratory, and also have studied practically outdoor sanitary work for six months, under an approved officer of health. This condition does not apply to medical practitioners, registered, or entitled to be registered on or before January, 1890.

THE ROYAL UNIVERSITY OF IRELAND.

The degrees of the university are granted on one year's acts, i.e., the matriculation examination of this university (none other will suffice) and a "first university examination" at the termination of the first year. The cost of the M.B. and M.Ch. of the university, with all the necessary curriculum, is about £125. Some of the arts examinations are conducted, not only in Dublin but at certain local centres.

The university confers the following medical degrees:—

M.B., M.D., B.Ch., M.Ch., B.A.O., M.A.O.; in sanitary science, a special diploma; in mental diseases, a special diploma.

All degrees are open to persons of either sex.

The university examinations are held in the spring, beginning about May 1st, and in the autumn, beginning about September 24th.

All candidates for any degree must pass the matriculation examination and the first university examination.

The course for the degree of M.B., B.Ch., B.A.O., extends over five years.

Students will be admitted to the first university examination after one year from matriculation. Fee, £1.

The course consists in three previous examinations and one degree examination; one at the end of each year. Fee for each primary, £1; for the degree, £2; for the diploma, £10.

In addition the following degrees are granted:—Diploma in Sanitary Science.—Conferred only on graduates in medicine of the university of one year's standing. Fee, £2. Subjects.—Climatology, chemistry, geology, physics, vital statistics, hygiene, sanitary law.

The M.B. Degree.—Conferred only on graduates in medicine of the university of three years' standing. Fee, £5. The examination will comprise medical diseases, and the theory and practice of medicine, including pathology.

The M.Ch. Degree.—Conferred only on graduates in medicine of the university of three years' standing. Fee £5.

The examination comprises surgery, both theoretical and operative; surgical anatomy; ophthalmology and otology.

The Mastership of Obstetrics.—Conferred only on graduates in medicine of the university of three years' standing. Fee £5.

Examination comprises midwifery and diseases of women and children.

Honours, &c.—First Examination in Medicine. Two first exhibitions of £23 each, and two second of £10 each.

Second Examination in Medicine.—Two first exhibitions of £25 each and two second of £15 each.

Third Examination in Medicine.—Two first of £30 each, and two second of £20 each.

Medical Degrees Examination.—Two first of £40 each, and two seconds of £25 each. One travelling medical scholarship of £100. One medical studentship of £200 per annum, tenable for two years.

ROYAL COLLEGE OF PHYSICIANS (L.R.C.P.I.)
AND SURGEONS (L.R.C.S.I.).

The examinations held conjointly by the two colleges are the inlet of most Irish students to the profession, especially of those educated in Dublin. The course, as in other bodies, extends over five years, with examinations at the end of the first, second, third, and final years, these examinations being conducted by examiners chosen by each of the colleges for the subjects appropriate to them. The five years may be described as—first, preparatory; second, theoretical; third and fourth, application of the theory to practical work; and, final, strictly practical in hospitals, general and special. The regulations are so voluminous that an epitome of them would

be unsatisfactory, and we recommend students to apply for the official programme to the Secretary of the Committee of Management, College of Physicians.

The total of the examination fees, spread over the four examinations, is £42, while the school and hospital fees if taken in Dublin, amount to £124 19s., making altogether £167, exclusive of "grinding" or of re-examination fees which have to be paid in case the candidate fails to pass in all the subjects of his examination at the one time. The cost of education is much less if taken out in Belfast, Cork, or Galway, at a Queen's College.

All information may be obtained from the Secretary of the Committee of Management, College of Physicians.

PROFESSIONAL EXAMINATION.

Every candidate must pass four examinations—one at the end of each session.

APOTHECARIES HALL OF IRELAND (L.A.H.).

This body is now authorised to grant a complete qualification in medicine, surgery, and midwifery, recognised and registrable under the Medical Act of 1886, and entitling the holder to occupy medical appointments in all the public services. It also confers the legal right to dispense medicines in Ireland. The examinations will be held on the third Monday in January, April, July, and October, and the requirements in respect of studies will be approximately the same as those of the conjoint examinations of the Royal Colleges of Physicians and Surgeons in Ireland. The examination fees payable for the qualification of L.A.H. will be as follows:—First professional, £5 5s.; second, £5 5s.; third, £5 5s.; final examination, £6 6s.

A candidate is allowed for each professional examination which he has completed at any other licensing body, except the final. If he has passed only in part of his subject in a given division, he has to pay the whole of the fee for that division.

The fees for re-examination are for each subject, £1 1s., excepting in the subjects of chemistry, pharmacy, surgery, and medicine, the fees for which are £2 2s.

The fee for final alone, £15 15s. Candidates may be admitted to a special examination under special circumstances, at an extra fee of ten guineas.

Candidates already on the *Register* will receive the diploma of the Hall on passing an examination in medicine, surgery, midwifery, and pharmacy, and paying a fee of ten guineas. If medicine or surgery are required, two guineas extra will be charged. The candidate will be exempt from each of the above subjects, which are covered by his previous qualification or qualifications.

THE PHARMACEUTICAL SOCIETY OF IRELAND.

The above Society grants the diplomas of Pharmaceutical Chemist and Assistant to Pharmaceutical Chemists, and of Registered Druggist. The pharmaceutical chemist is not entitled by the Society's licence to prescribe. In this respect he differs from the apothecary. All persons who keep open shops for compounding prescriptions must hold the licence of the Pharmaceutical Society or Apothecaries' Hall. Pharmaceutical chemists under the Act are entitled to hold the office of apothecary to district lunatic asylums, county gaols, and, by a recent order of the Local Government Board, may also hold similar office in workhouses and dispensaries, and are also eligible to compete for dispenserships in naval hospitals. The registered druggist is entitled to sell poisons, but not to compound prescriptions. The Society, according to the Calendar, which was corrected to December, 1898, had the names of 528 pharmaceutical chemists, 305 chemists and druggists, 406 registered druggists, and 14 assistants to pharmaceutical chemists—in all 1,253 persons—on its registers.

Lectures are delivered on materia medica, and botany and chemistry, in the Society's schools, which will be reopened in October.

The Introductory Lectures in botany and materia medica will be delivered on October 5th, by Professor Falkiner, and that on chemistry by Professor Tichborne on October 1st.

ROYAL COLLEGE OF SCIENCE.

DEPARTMENT OF SCIENCE AND ART.

This College, situate in Stephen's Green, Dublin, supplies a complete course of instruction in science applicable to the industrial arts, especially those which may be cast broadly under the heads of chemical manufactures, mining engineering, physics, and natural science. A diploma of Associate of the College is granted at the end of the three years' course. There are four Royal scholarships of the value of £50 each yearly, with free education, including laboratory instruction and drawing, tenable for two years. Two become vacant every year. They are competed for by the associate students with certain restrictions at the end of the first year. The chemical, physical, zoological, and botanical, geological, and mineralogical laboratories and drawing schools are open daily for practical instruction. The session commences on Tuesday, October 3rd.

The course of chemistry, physics, botany, geology, and mineralogy, and zoology are recognised by the Royal University of Ireland, and certificates of attendance are granted to medical and other students, attending these courses, as also the courses of chemical, physical, zoological, and botanical and geological laboratories.

THE EDUCATIONAL PROSPECT.

THE Irish teaching centres, speaking generally, were fairly busy last year, and there seems to be no sufficient reason to fear that there will be a falling off in the coming Medical Session. There was a retrogression in the Dublin Schools, but it was more than compensated for by an increase in Belfast and Cork. The total output of students qualifying from Ireland showed a material advance, but the profession was most manifest in the number of candidates for the Scotch Colleges, although the Dublin Colleges and Universities participated to some extent.

THE IRISH MEDICAL SYSTEM.

The system of medical teaching in Ireland differs from that in England in important particulars. In London each clinical hospital has its attached medical school, which is fully equipped, and which educates the students of that hospital, and very seldom those of any other. In Dublin, on the contrary, the hospitals and schools are entirely separate (except that Sir Patrick Dun's Hospital is officially connected with Trinity College), and a student of any hospital is free to enter the whole or any part of his course at any school or hospital he pleases. As might be expected, religion, social rank, and locality of residence have their influence in causing certain classes of students to resort to schools and hospitals suitable to their condition. But scholastic or collegiate regulations impose no restrictions as to the place of study, and as the school and hospital fees are paid in detail in Dublin, and not in a lump sum, as in London, the pupil is absolutely free to do as he pleases.

In London the student bargains with his hospital and schools, in the first instance, for a complete course of instruction, for which he pays, in whole or part, in advance, and his entire study is conducted within the one institution. In Dublin, on the contrary, the student enters for hospital and for courses of study separately, and takes the courses at any school or hospital he pleases which "gives best value," migrating from one school or hospital to another as he thinks fit.

LODGING AND LIVING OF IRISH MEDICAL STUDENTS.

There is, unfortunately, in Dublin no proper organisation for domestic accommodation of medical students. For those who are passing through Trinity College rooms and "commons," or meals, are provided at fixed rates. Those who can afford to pay £8 6s. or £7 7s. per month for their lodging and maintenance may find accommodation in the family of some medical man who receives boarders, in which case they become members of the family for the time being, and subject to its discipline. The majority of Dublin students, however, take a lodging

in some economical locality, or they "chum" with some other student for the purpose. It is usual to contract with the lodging-house keeper for board or partial board, but some students cater for themselves. On the whole, the domestic arrangements of the Dublin student are unsatisfactory, cheerless, and not calculated to encourage home comforts or home discipline.

COST OF EDUCATION IN IRELAND.

The total expense of the course of study requisite for the Conjoint Diplomas of the Colleges of Surgeons and Physicians, or the College of Surgeons and Apothecaries' Hall, including "grinding" and all the necessary professional expenses, totals up to about £124 19s., spread over five years, and the cost of them is the same in all the Dublin Schools, but if they be taken out in the Queen's Colleges the amount is very much less.

This, with the examination fee of £42 for the Conjoint Diplomas of the College of Surgeons and College of Physicians, represent the essentials. Thus, the absolute payment will amount to somewhere about £166 19s., taking the minimum mode of payment. So that, assuming the extras or voluntary costs are incurred, the total will vary, say from £170 to £200. "Grinding" usually costs £5 5s. for each of the four examinations, but if a student needs "private grind" in special subjects he must pay extra for them.

This sum, or something like it, may be expended by the student or his parent paying for lectures, &c., and examination fees as they accrue, and there is not the least difficulty about obtaining the information needful for their guidance if they like to act independently, but if they prefer to pay a lump sum down, such payment will secure to a pupil the advantage (?) of being "apprenticed" to a teacher who will undertake all monetary responsibility for his education, and may be able to give him some special advantages as his own pupil at hospital, but the so-called apprenticeship is very generally a simple contract for the payment of fees, and involves but little of that special teaching which is due by a master to a true apprentice, and as it deprives the student of his independence in selecting the schools and hospitals which suit him best, we advise him not to be an apprentice unless he knows very well indeed the master to whom he entrusts himself. All the Dublin schools now require fees to be paid in advance, and the remainder on the issue of the certificate, while some will give credit for the whole amount. Most of the apprenticeship holders will accept payments by instalments.

IRISH PRELIMINARY EXAMINATIONS.

The first work of the student is to pass a preliminary examination, without which he cannot get credit for any medical studies pursued. The next is to commence medical study. This he does by entering for lectures at a medical school. From the school registrar he gets a form of certificate, and his third act is to take it or send it to the Branch Medical Council, 35 Dawson Street, Dublin. He is thereupon placed upon the Register of Medical Students (without fee) and his period of study counts from that date. He must register at the earliest possible moment, or he will lose credit for his work.

The only preliminary examination held specially for medical students is now held conjointly by the Royal Colleges of Physicians and Surgeons, but other examinations, e.g., the public entrance at Trinity College, the matriculation of the Royal University, the Intermediate Education passes in the required subjects, and all other examinations recognised by the General Medical Council are accepted as equivalent.

The Preliminary is held in March and September, in the subjects specified by the General Medical Council.

DATE OF ENTRY IN IRELAND.

The entry of names and commencement of study in Ireland is supposed to date from the 1st of October in each year, but the session really does date from the 1st of November, and the entry of names may be delayed by the dilatory to the 25th of the same month, but it should be recollected that no credit is given for studies or attendance until the entry is regularly made. The student must attend three-fourths of the lectures

delivered, and if he loses a fortnight at the beginning he must "pull up" afterwards by constant attendance.

The student begins work attending a recognised medical school each morning at ten o'clock, and occupying his day, to five p.m., between lectures and dissections. His vacations are a fortnight at Christmas and a week at Easter, and he finally returns home at the end of June.

MEDICAL SCHOOLS AND HOSPITALS IN DUBLIN.

The clinical hospitals in Dublin are ten in number, exclusive of the Cork Street Fever Hospital, three lying-in hospitals, two ophthalmic hospitals, a dental hospital, the National Children's Hospital in Harcourt Street, the Orthopaedic Hospital, and the other special institutions. Some of the clinical hospitals, though they have no actual or official connection with any school, are in close affinity with certain teaching bodies, while others, again, are without any special connection with any school. While, however, such affiliation of a school or hospital may exist, it should be remembered that the Dublin schools and hospitals are open to all comers, and the student is competent to attend any hospital or any school he wishes, and to change his place of instruction from year to year as he may see fit.

The Irish Licensing Bodies require attendance on hospital for 27 months (i.e., three winter sessions of 6 months and three summers of 3 months) within the five years of study. The fee at all general hospitals is £8 in winter, and for the summer £6, or £12 for the entire session of 9 months if taken together.

The names of the Professors, Lecturers, and Hospital Staffs of the following Schools and Hospitals, are not included in this place, being found in the advertisement of each Institution, as indicated on next column, in our advertising columns.

THE SCHOOL OF PHYSIC is a medical school formed by an amalgamation of the School of Trinity College and of the College of Physicians. Some of the professors in the schools are *ex officio* medical officers of Sir Patrick Dun's Hospital. The school is freely accessible to all students, and the instruction provided occupies a high rank.

The arts students of the University have certain advantages in attending. In their "sophister" years medical students may drop certain languages out of their arts course. Every student of the school must be matriculated by the senior lecturer, for which a fee of 5s. is payable, but he need not attend any of the arts course unless he desires to obtain a university licence or degree, in medicine, surgery, and midwifery. No student is permitted to matriculate unless he has passed the entrance examination in Arts in Trinity College, the preliminary examinations of the Royal University, of the College of Surgeons, or some other examination recognised by the General Medical Council.

Two Medical Scholarships are given annually at the School of Physic, valued £20 per annum, tenable for two years, the examinations for which are held each year in June, in the following subjects:—Anatomy and Institutes of Medicine, zoology, chemistry, botany, and experimental physics. Three-fourths of the lectures must be attended, and a daily roll is marked by each professor.

THE ROYAL COLLEGE OF SURGEONS IN IRELAND SCHOOLS OF SURGERY.—By the amalgamation of the Carmichael College and the Ledwich School with the School of the Royal College of Surgeons the combined schools form the largest medical teaching body in Ireland. These schools are attached by Charter to the Royal College of Surgeons. They are carried on within the College Building, and are specially subject to the supervision and control of the Council, who are empowered to appoint and remove the Professors, and to regulate the methods of teaching pursued. The Buildings have been reconstructed, the capacity of the dissecting room nearly trebled, and special histological, pathological, bacteriological, public health, and pharmaceutical laboratories fitted with the most approved appliances in order that students may have the advantage of the most modern methods of instruction.

Lady Students.—Ladies are eligible for all the Diplomas granted by the College, separate rooms have been provided, and careful provision is made for their instruction and comfort.

Prizes.—The Carmichael Scholarship, £15; the Mayne Scholarship, £15. The Gold and Silver Medals in surgery, and the Stoney Memorial Medal in anatomy will be awarded at the end of the session. The "Barker" Prize, £21 is also open to students of the school.

Class Prizes of £3 and £1, accompanied by medal if sufficient merit be shown, will also be given in each subject. Prospectus can be obtained on application to the Registrar.

THE CATHOLIC UNIVERSITY SCHOOL is situated in Cecilia Street, Dame Street. It prepares students for all medical examinations, particularly those of the Irish College of Physicians and Surgeons, and the Royal University of Ireland. The school has recently been rebuilt and refitted, its working space having thereby been nearly doubled, and several new laboratories including those for the study of Bacteriology and Public Health have been added. The institution has also been recently chartered, and it is now controlled by a Board of Governors.

There has been formed in connection with the school a "Medical and Scientific Society" for the discussion of medical and scientific subjects.

The following exhibitions are awarded annually:—Two first year's, value, £12 10s. each; two second year's, value, £10 each; two third year's, value, £12 12s. each; one third year's Royal Exhibition of £12 10s.; one final of £12 10s.; and two large gold medals, besides several other class.

A guide to students commencing medicine may be obtained free on application to the Registrar.

THE QUEEN'S COLLEGES—BELFAST, CORK AND GALWAY.

THESE three important academic institutions were the special schools of the Queen's University. They have ceased to have any direct relation to a central examining body, but educate students for all colleges and degrees, and are maintained, as hitherto, by a handsome Government grant. The same curriculum as that heretofore adopted will be continued. The various exhibitions and scholarships will still be available. Each college has the disposal of about £1,500 per annum in scholarships and prizes. The curriculum is generally well adapted for preparation for the Royal University examination. The colleges are well adapted for high-class technical education, having lecture rooms provided with every appliance necessary in the modern training of a medical student. The great want in the colleges of Cork and Galway is a summer session. This necessitates the loss to the student each year of three available working months. The colleges are completely equipped with students' reading rooms and lending libraries and refreshment rooms, and with all adjuncts to collegiate life, such as literary societies and athletic organisations. The students do not, however, reside within the college, but halls of residence and licensed boarding houses are provided for those who do not live with friends. The expense of living in the collegiate towns is quite moderate. The course of lectures in the winter session must be diligently attended, no student obtaining a certificate who

has not put in three-fourths of a course. The winter medical session commences on October 29th and ends about Easter. The scholarships examinations are held in October. A detail of the prizes and exhibitions in medicine, the names of the professors, and other information may be found in the advertisements of this issue, and full details may be had on application to—

Belfast, John Purser, LL.D., Registrar.

Cork, Alexander Jack, M.A.

Galway, Edward Townsend, M.A.

CLINICAL HOSPITALS.

RICHMOND, WHITWORTH, AND HARDWICKE HOSPITALS.

—The accommodation of these hospitals is as follows:—Hardwicke Hospital, 120 beds; Whitworth Hospital, 82 beds; Richmond Hospital, 110 beds—total, 312 beds. These hospitals are visited each morning at 9 o'clock by the Physicians and Surgeons, and in addition to the usual bedside instruction clinical lectures are delivered on the most important cases. Special instruction is also given on various branches of medicine and surgery. The Truss Establishment for the distribution of trusses to the ruptured poor of Ireland is connected with these hospitals. There are very large ophthalmic, aural, throat, and gynecological dispensaries, and instruction in these important subjects is given. Eight resident clinical clerks are appointed each half-year, and provided with furnished apartments, fuel, &c. The appointments are open not only to advanced students, as formerly, but also to those who are qualified in medicine or surgery. A house surgeon for the Richmond Hospital and a house physician for the Whitworth and Hardwicke Hospitals are elected annually, and receive a salary. The Richmond Lunatic Asylum, containing 1,600 beds, adjoin these hospitals.

MEATH HOSPITAL AND CO. DUBLIN INFIRMARY.

—This hospital was founded in 1753, and now contains 160 beds available for clinical teaching. A new building for the isolated treatment of fevers has recently been added. The certificates of this hospital are recognised by all the universities and licensing bodies of the United Kingdom. Medical and surgical resident pupils and clinical clerks and dressers are appointed every six months, and a house surgeon is elected annually. A prospectus giving the complete arrangements for medical and surgical classes for the coming session may be obtained from the secretary of the Medical Board, R. Glasgow Patteson, F.R.C.S., 20, Lower Baggot Street, Dublin.

THE ADELAIDE MEDICAL AND SURGICAL HOSPITALS are in Peter Street, and occupy a central position within a few minutes' walk of the College of Surgeons and Trinity College. From October 1st the physicians and surgeons visit the wards, and give instruction at the bedside at the advertised hours. There is a large detached fever hospital, and also wards for infants and children. Operations are performed, except in cases of urgency, at 10 a.m. on Tuesday, Thursday, and Saturday. Special hours are devoted to clinical instruction in the diseases peculiar to women, and students are individually instructed in the use of the stethoscope, ophthalmoscope, laryngoscope, and microscope; also special instruction is given on practical pathology and X-ray photography. Three resident pupils are selected half-yearly and a house surgeon annually. Prize examinations, including examinations for the Hudson Scholarship, £30 and a gold medal, and a senior prize of £10 and a silver medal, in addition to surgical and medical prizes, are held at the termination of the session. The large dispensaries afford facilities for the study of eye, ear, throat, and cutaneous diseases, as well as of minor surgery and dentistry. Further particulars from Dr. Heuston, 15, Stephen's Green North.

SIR PATRICK DUN'S HOSPITAL is situated on the south-eastern side of the city, and about half a mile from the University School of Physic. It is officered exclusively by the professors and examiners in that school. Formerly all University students were compelled to attend this hospital, which was purely a medical institution, but some years ago the obligation was removed, and the hospital was opened for surgical cases. It is now perfectly free to all students.

THE CITY OF DUBLIN HOSPITAL.—This hospital is situated in Upper Baggot Street, about ten minutes' walk from the Royal College of Surgeons and Trinity College. It has just been enlarged and improved to a very considerable extent. A special course of instruction is given on ophthalmic and aural disease. There are special wards for the treatment of diseases of the eye, of children, and of women, and practical instruction is given on diseases peculiar to women, also a separate building for infectious diseases. Clinical clerks to the physicians and dressers to the surgeons are appointed from the most deserving of the class. An entirely new operation theatre, sterilising room, and anæsthetic room, are being constructed in accordance with the most modern surgical requirements, and are now almost completed. A house surgeon is elected annually, and resident medical and surgical pupils are appointed from among the past and present students of the hospital. Operations are performed on Tuesdays, Thursdays, and Saturdays, at 10.30 a.m. Full particulars can be had on application to Mr. G. Jameson Johnson, Hon. Sec. Med. Board.

MATER MISERICORDIÆ HOSPITAL.—This hospital, the largest in Dublin, containing 335 beds, is open at all hours for the reception of accidents and urgent cases. Fifty beds are specially reserved for the reception of patients suffering from fever and other contagious diseases. A course of lectures and instruction on fever will be given during the winter and summer sessions. A certificate of attendance upon this course to meet the requirements of the various licensing bodies, may be obtained. Opportunities are afforded for the study of the diseases of women in the wards under the care of the obstetric physician, and at the dispensary held on Tuesdays and Saturdays. Lectures on clinical gynecology will be delivered on Saturdays at 11 a.m. Ophthalmic surgery will be taught in the special wards and dispensary. A special course of instruction in pathology and bacteriology, as applied to medicine, will be given. Connected with the hospital are extensive dispensaries, which afford valuable opportunities for the study of general, medical, and surgical diseases, accidents, &c. Four house physicians and eight house surgeons will be appointed annually. Ten resident pupils will be elected, each to hold office for six months, from the most attentive of the class. For the current session the elections will take place in November and in May. Dressers and clinical clerks will be appointed, and certificates will be given to students who exhibit proficiency and punctuality in performing their duties. Leonard prizes: one gold and one silver medal will be offered for competition annually in the subject of medicine, and one gold and silver medal in the subject of surgery. Junior Leonard prizes: two prizes of the value of £3 and two prizes of the value of £2 will be offered for competition in medicine and surgery, respectively. They will be awarded on the aggregate of marks gained by reports of cases, and at a clinical examination to be held at the close of the summer session.

MERCER'S HOSPITAL, William Street, founded A.D. 1707.—This hospital educates students of all schools. It is situated in the centre of the metropolis, in the midst of a densely-crowded population, and its doors are open at all hours for the reception of accidents and acute cases. Dispensaries are held daily, and are largely attended. Special instruction is given in cutaneous, infantile, gynecological, and ophthalmic diseases. From the large number of accidents which, from its position, come to the hospital, students are offered ample opportunities of rendering themselves familiar with the nature and treatment of disease in its various forms and of obtaining dexterity in the dressing and manual operations of minor surgery. In addition to the new wing built some years ago, another wing, facing Stephen's Green, has been completed, which contains a new operating theatre, students' room, lavatory, dispensary department, pay wards, and nurses' homes.

ST. VINCENT'S HOSPITAL, Stephen's Green, Dublin, was established in 1834. The hospital has 160 beds constantly full, and in connection with it there is a largely attended dispensary, a convalescent home, and a nurses' institute. In addition to the ordinary clinical instruction, systematic

courses of lectures are given in each department of medicine and surgery, and are illustrated by cases in the hospitals. The resident officers consist of a house surgeon, a house physician, and four resident pupils. Three clinical lectures are delivered daily in the wards, illustrated by selected cases, and beginning at 9 a.m. A special feature of this hospital is the division of the students into senior and junior classes, thus providing for their systematic and appropriate instruction from the beginning to the end of the course.

Two gold medals and other valuable prizes and certificates of merit are awarded at the end of each session.

A prospectus can be had from Dr. McHugh, 25, Harcourt Street, Stephen's Green.

The Introductory Address will be delivered by Dr. Tobin, on Tuesday, October 3rd, at 4.30 p.m.

SPECIAL HOSPITALS.

The special hospitals of Dublin are the Rotunda, Coombe and National Lying-in Hospitals, Cork Street Fever Hospital, the Royal Victoria Eye and Ear Hospital (amalgamation of St. Mark's Ophthalmic Hospital, and the National Eye and Ear Hospital), the Dental Hospital, the Throat Hospital, the Orthopædic Hospital, and the Children's Hospitals in Harcourt Street and in Temple Street.

THE ROTUNDA HOSPITAL.—This, the largest and best-known lying-in hospital of the United Kingdom is every year becoming more appreciated as a school of midwifery, and of late, more especially, as affording peculiar advantages both to the student and the practitioner for acquiring a thorough knowledge of gynecology. It contains two distinct departments—viz., the lying-in hospitals, into which about 1,600 cases of labour are admitted annually; and the hospital for the treatment of diseases peculiar to women, into which some 500 patients are now admitted during the course of the year. The present master, Dr. Purefoy, was previously well known as Gynecologist to the Adelaide Hospital. There is a large extern maternity in connection with the hospital, more than 2,000 women being attended during the past year at their own homes, and also a large daily dispensary for the treatment of the diseases peculiar to women. Every facility is afforded for the study of the special departments of medicine to which the hospital is devoted, and both students and midwives are granted a diploma on passing an examination. Two clinical clerks, at a salary of £50 per annum each, are appointed every six months from among the students who have attended the full course of instruction in the hospital. A considerable number of female pupils are also yearly trained as nurse tenders and midwives.

NATIONAL MATERNITY HOSPITAL.—This institution, under the mastership of Dr. Barry and Dr. H. Horne, is situated in Holles Street, close to Sir Patrick Dun's.

CORK STREET FEVER HOSPITAL is the only special fever hospital in Dublin. It is supported mainly by an annual Government grant. All particulars may be obtained on application to the Registrar and Resident Medical Officer.

NATIONAL CHILDREN'S HOSPITAL for the treatment of all non-infectious diseases peculiar to children, 87 and 88, Harcourt Street, Dublin. The hospital, with which the Pitt Street Children's Hospital, founded in 1821, was amalgamated, is capable of containing 50 beds for the reception of cases of deformity and all other forms of surgical disease. There is a large general dispensary for extern patients held daily from 10 to 11. Operations are performed on Saturday at 12 o'clock. Practitioners and students can attend on application to Mr. Ormsby.

DUBLIN ORTHOPÆDIC HOSPITAL, Great Brunswick Street, containing 40 beds for the treatment of every class of deformities and for the practice of orthopædic surgery. This institution is under the management of Mr. Swan.

THE ROYAL VICTORIA EYE AND EAR HOSPITAL consists—until the new combined hospital is erected—of the two institutions which have, heretofore, given special instruction in ophthalmology separately. They are:—

ST. MARK'S OPHTHALMIC HOSPITAL AND DISPENSARY.—This hospital was founded by the late Sir William Wilde, and contains 50 beds. Clinical lectures are delivered on the mornings of Mondays, Tuesdays, Thursdays, and Fridays at 11 o'clock, and operations are performed on Wednesdays and Saturdays at the same hour.

NATIONAL EYE AND EAR INFIRMARY, Molesworth St.—This hospital contains thirty beds. Clinical instruction in diseases of the eye, including the use of the ophthalmoscope, is given daily. Operations at 12 o'clock. Instruction in aural surgery is also given. Students may enter their names for a three months' course any day. Afternoon classes for practical instruction in the use of the ophthalmoscope, &c., and for the demonstration of cases, are formed from time to time by the assistant surgeons.

IRISH PUBLIC SERVICES.

SINCE the issue of our last Students' Number a vital change has taken place in the Irish Poor-law Medical Service—the service which has, heretofore, absorbed most of the Irish rising medical generation. By the Irish Local Government Act the administration of the system, the appointment and payment and allocation of duties of medical officers was transferred from the old Boards of Guardians composed, in due proportion, of members elected by the local voters and members who acted *ex-officio* in virtue of property qualifications to new boards composed wholly of the elected representatives. This change has had the most disastrous effect upon the service. The *ex-officio* guardians frequently perpetrated politico-religious jobs when they had the upper hand but, in a general sense, they inclined towards justice and decency of administration, and, even when they were in a minority, they maintained a drag upon the unscrupulousness of the village agitator, and the doctor managed generally to live in charity with his employers. All this is changed by the Act. The *ex-officio* guardians—i.e., the local gentry were, thereby, eliminated, and the sole control of the service has been transferred to the elected Guardians, who have unhesitatingly seized the opportunity to sweat and worry the dispensary and workhouse medical officers. More work has, in every position, been imposed upon them, and their former miserable pittance has been, in every item, whittled down. If the Medical Officer does not happen to be of the predominant religion or politics a campaign is quietly organised to worry him into resigning his office, and a popular candidate is held in readiness to take the office when he does. We need go no further than to say, which we do in perfect honesty, that the Irish Poor-law Medical Service is one to get out of as speedily as possible, and one quite unfit for a self-respecting gentleman. Leaving this latter class out of consideration, there are, no doubt, a number of fifth-class practitioners whose professional or social attainments do not entitle them to any better position than that of running footmen to the elected guardians to whom their candidature will, no doubt, be acceptable. To all others who contemplate entering the Irish Poor-law service we emphatically say, Don't!

THE POOR-LAW.

THE newly-qualified medical practitioner who may elect to try his luck in the Irish provinces sets his hopes in the great majority of instances upon obtaining one or more Poor-law medical appointments in some district where there is hope of private practice. There are 159 workhouses and about 813 dispensary medical officers, besides apothecaries.

The number of vacancies that occur annually averages 100. The salary in this service averages about £114, and when it is taken into consideration that in the vast majority of rural districts it is usual to keep one or more horses, the average area being from forty to sixty square miles, it is plain that there will not be a large margin left from the public emoluments. The medical officer is also *ipso facto* the registrar of births, marriages, and deaths, and medical officer of health for the district, under the Public Health Act passed in '73 and amended in '78.

The former office, in country districts, yields between £5 and £10 a year, and the emoluments of the latter appointment in very few cases reach £20, averaging about £12. The medical officer is also vaccinator for the locality, and is required to vaccinate everyone who wishes to come. For each patient his fee of 2s. is paid, along with his salary, by the guardians, and the sum total of those fees varies, according to the populousness of the district, from £4 to £100, an average for the provinces being about £10. Despite the miserable salary, and the very many discomforts of dispensary life, these appointments are generally eagerly sought for—first, because they afford the new comer a certain, though hardly-earned salary, to supplement his private earnings; and secondly, because, if not secured by the new comer, they would of necessity bring a competitor for office into the field, and inasmuch as private income is of far greater import than public earnings, country medical practitioners are obliged to undertake the public duty in order to save themselves the monopoly of their private emoluments.

Appointments.—The qualifications required by the Poor-law Commissioners are a licence in surgery, in medicine, and in midwifery; the candidate must also be twenty-three years of age.

The appointment lies with the guardians, who elect by vote. As politics and religious feeling run high in Ireland, these elements enter largely into the election of Poor-law medical officers. Family interest also possesses great weight.

The candidate will do well to bear these facts in mind, as his personal attendance on the day of election will be required, and whatever other qualification he may have, he will then find that his compatibility in these respects with the majority of the committee is essential; and accordingly, he had better first make himself acquainted with the local peculiarity, whatever it may be, before he enters on his candidature, otherwise, in all probability, any expenditure that he may make in the matter will be simply thrown away.

Duties.—The duty of the dispensary doctor is twofold. He is to attend his dispensary on a given day or days in the week. Frequently there are two dispensaries in the district, separated from each other by several miles, and he will have perhaps to attend two days a week. He has also to visit at any hour of the day or night a sick person for whose relief a visiting ticket has been issued by a member of the committee or the relieving officer, and to continue his attendance as often as may be necessary to the termination of the same. Moreover, he has a great many registry books to keep and a multitude of returns to make, and in the majority of districts he has to make up all the medicines for the poor.

The pressure of these duties is in the greatest degree dependent on the goodwill of the guardians. If the medical man be a favourite with his masters they will give him very little trouble with "scarlet runners," as the visiting tickets are, from the colour of the paper on which they are printed, humorously called, and will be unwilling to trouble him even with cases deserving of personal attendance.

If, on the other hand, it is his misfortune to come in contact with some of the half-bred guardians, who know nothing of the treatment fit for an educated gentleman or cherish a personal spite, the discharge of his duties may become simply unbearable. He may be peremptorily summoned in any weather, at any hour, and to any distance, to a case which he may probably find to be altogether trivial, or to a person whom he may know to be perfectly well able to pay—aye, even to the committee-man's own brother or daughter.

Workhouse Hospitals.—The number of unions in Ireland

is 159, to each of which is attached a medical officer, who is appointed and controlled by the board of guardians in the same manner as the dispensary surgeon is by his committee. The salary is usually better than that of the dispensary doctor, and the duties of a more easy and satisfactory description inasmuch as they are confined to daily attendance at the workhouse hospitals, and no night visits out of doors or any long journeys across the country are involved.

THE IRISH LUNACY SERVICE.

This service, at present, affords a comfortable livelihood for 22 Resident Medical Superintendents and 32 Assistants. The Superintendent receives a handsome salary and allowances ranging, according to the number of inmates of the asylum, from £500 to £1,000 a year, and the Assistants receive salary and emoluments averaging about £200 a year. There are also Visiting Physicians receiving about £120 a year, but this class of officers is being allowed to die out, and no new appointments will be made.

The Superintendents and Assistants are supposed to devote their whole time to their duties and not to take any private practice, and if they attend to their business it will give them plenty to do, but complaints have been made to us of their trying to poach on the professional preserves of their neighbours occasionally.

Heretofore the appointments of Medical Superintendents have been in the patronage of the Lord Lieutenant, but, under the new Local Government Act, they will be in the hands of the County Councils, with the proviso that no one shall be appointed who is not a fully registered practitioner with five years' service as Assistant. The Assistant has been, heretofore, appointed by the Board of Governors, and will, in future, be appointed by the Committee of the County Council to which the management of the asylum is entrusted. In addition to these officers, there are, in certain larger asylums, Clinical Residents, who receive about £50 a year and full allowances. Those appointments afford excellent introduction to the higher places in the service.

It will be seen that the Irish Lunacy service is well, but not too well paid, not only for the valuable and responsible services rendered, but for the *désagrémens* of living in a lunatic asylum, but it is available for only a very few who have political or personal influence to obtain appointments.

OTHER APPOINTMENTS.

There are, in addition to those which we have mentioned, certain emoluments open to medical practitioners in special localities. They are:—

1. Attendance on the Royal Irish Constabulary.
2. Attendance on the Coast Guards.
3. Factory Surgeoncies.
4. Attendance upon the depot soldiers when not otherwise provided for.

The Constabulary are paid for at the rate of 2s. per month for each member of the force on duty in the district, including the wives and children of the men but not of the officers. This includes the supply of medicines. The appointment to this position rests with the Inspector-General of Royal Irish Constabulary, who usually acts upon the advice of the local District Inspectors as to the convenience of the men.

The Coastguard appointments are, of course, only on the coast line. The duty of the Medical Officer is to attend the men when sick and to examine candidates either for admission or for superannuation. The fees vary from 5s. to 2s. 6d. per visit. The appointments rest with the Admiralty, but are usually secure for the local Poor-law Medical Officer.

Factory surgeoncies are in the gift of the Chief Inspector of Factories in Whitehall, and are, of course, available only in the few districts in which there are factories to inspect. There is a set scale of payment by the factory owner to the inspector for this work, but we believe it is not adhered to and, in some districts at all events, the emolument is a matter of arrangement. The amount depends, of course, upon the size of the factory, the position being, in Dublin or Belfast or in other large

manufacturing centre, a lucrative one but in other places scarcely worth taking. The attendance on the military depots is not worth mentioning.

Scotland.

THE Northern part of Great Britain has made a name for herself for many things. Scotland is the land o' cakes, of porridge, of the kilt, of thrift, the mother of golf; but she has also earned a well-merited reputation for the excellence and thoroughness of her system of education, and for the undoubted success of her alumni dating, not only from yesterday, but from some centuries back. She still maintains her educational system at the high level to which it long ago attained, and, with a less numerous population inhabiting her whole area than that of London alone, keeps up four venerable and historic Universities, all with a honoured past and a magnificent record. The Universities of Edinburgh, Glasgow, Aberdeen, and St. Andrews have sent forth many illustrious graduates in all the different branches of higher learning; few schools can show so illustrious a series of medical giants. In Edinburgh and Glasgow those who do not aspire to the honour of the University degree can obtain college diplomas and excellent medical teaching from the extra-mural schools.

The inhabitants of Scotland have always evinced a deeply rooted dislike to constraint; the regulations of their Universities are examples of this. The student in Scotland is his own master; he lives where he likes, dines where he pleases, and can clothe himself in any kind of garment he chooses. In but one of the Universities have students to don gowns. No doubt the great freedom allowed students occasionally leads to unsatisfactory results, but the advantages which accrue from the system may be held to more than counterbalance the drawbacks. The student is no longer a schoolboy, amenable to a common discipline, and impelled towards pleasures; so alluring when against rules, so commonplace when free. He is only required by the authorities to attend with due regularity various compulsory classes, to give evidence of his diligence, and to conduct himself with proper decorum while within the University precincts. Several halls of residence for students have lately been established, but even here the students are their own masters. Absence of residential colleges implies the absence of college fees, and the invariable large extras incurred by college life.

Until recently the sole method of teaching medicine at these institutions consisted in the delivery of a stated number of didactic lectures and attendance on hospital practice; the students listened, took notes, and were supposed to be trained physicians and surgeons. Lately, however, although the lectures persist they are of a less theoretical nature, and are supplemented by numerous practical classes in which smaller numbers can receive greater individual attention. The large classes attendant at some of the universities render personal intercourse between the Professor and students impossible; but large classes (implying proportionate fees) compensate for this by permitting of a more extensive choice of teachers, and the probable appointment of the ablest men, and, what is more, their retention afterwards.

The co-existence of teaching and degree-granting universities and extra-mural medical schools in Scotland forms one of the most important factors in the system of medical education in the country. The extra-mural teacher, struggling for his own bread, naturally does his best; the professor cannot afford to fall behind, or his students will attend elsewhere. The medical education at the universities is the best of its kind, comprising courses on all branches of special medicine and surgery; at the extra-mural schools the special subjects are perhaps even better treated, as they are taught by specialists themselves. In the way of expense, there is little between the University course and the curriculum obligatory for the Licence of the Colleges. The minimum cost for five years' attendance for the Licence may be put down at £120, which includes class and examination fees; and at the universities at £146; a difference of about £25 a year. As the five years' course has been imperative in Scotland for five years, no note need be given as to the old four-year regulations. Anyone who commenced study before that date may be considered to be conversant with their main facts.

Perhaps the one blot upon the Scottish system of medical education at Universities arises from the plan adopted at their professional examinations of delegating the examiners' duties to the professors themselves, along with only one coadjutor for each subject. As University students are now allowed to attend one-half of the total number of courses required for graduation outside the University walls, it happens now and again that those who have done so in a subject, upon which they are examined by the professor teaching it, are placed at a disadvantage in not being thoroughly conversant with subjects specially lectured on by the examiner during the preceding session. The examining board for the diploma of the Scottish colleges, indeed, is largely made up of the extra-mural lecturers, but the number assigned to each subject is large enough to avoid the examination of a candidate by his own teacher in the majority of instances.

Apart from the educational attractions offered to students of medicine by the Scottish schools, a very important fact aids to explain the reason why so many students from all parts of the Empire enrol their names in their books: the cost of maintenance is less than in England. As a general rule the higher the latitude the cheaper is the living in Great Britain. Edinburgh and Glasgow are more economical than London; Aberdeen less expensive than they are.

UNIVERSITY OF EDINBURGH.

Four degrees in Medicine are granted: Bachelor of Medicine (M.B.), Bachelor of Surgery (Ch.B.), Doctor of Medicine (M.D.), and Master of Surgery (Ch.M.). The first two must be taken together, the last two may be taken separately.

No one is admitted to the degrees of Bachelor of Medicine and Bachelor of Surgery who has not been engaged in medical and surgical study for five years, after passing a preliminary examination in general knowledge in accordance with the medical ordinances. The degree of M.A. of a British University is held to supersede such preliminary examination. The subjects included in this general examination are English grammar and composition, English history and geography, Latin, arithmetic, and the elements of mathematics, and, in addition, as optional subjects, Greek, French, or German.

The *annus medicus* of each year is held to be constituted by at least two courses of not less than one hun-

dred lectures each, or by one of such course, and two courses of not less than fifty lectures each, exclusive of the clinical courses, in which lectures are given twice a week during prescribed periods. Two years of the five must be spent at the University, the remaining three years at any University of the United Kingdom, or other Universities or Medical Schools recognised by the University Court.

During the first four years the student must attend elementary botany, elementary zoology, physics, practical chemistry, practical physiology, practical pathology, and medical jurisprudence and public health during courses of not less than 24 months each; practical anatomy during two courses of not less than five months each; chemistry, anatomy, physiology, pathology, surgery; materia medica and therapeutics, medicine, and midwifery and the diseases of women and children, during courses of not less than five months each. Eight of these subjects must be taken at a University. He must attend a course of 25 meetings on practical pharmacy in a University or recognised school of medicine, or have dispensed drugs for a period of three months in a hospital or dispensary, or in an establishment recognised by the Pharmaceutical Society. He must attend a nine months' course in clinical medicine and in clinical surgery. During the fifth or final year he must be engaged in clinical study for at least nine months. In all, before graduation he must have attended for at least three years a hospital which accommodates no fewer than 80 patients, and possesses a distinct staff of physicians and surgeons, and he must have acted as clerk in the medical and dresser in the surgical wards of such a hospital, or the practice of a dispensary, or of a physician or surgeon. He must have had approved opportunities of studying at a hospital, post-mortem examinations, fevers, diseases of children, ophthalmology, vaccination, and mental diseases.

He must personally attend at least twelve cases of labour under the superintendence of a registered medical practitioner, or six such cases, and, for at least three months, the practice of a midwifery hospital in which practical instruction is regularly given.

Every candidate must deliver before the 31st day of March of the year in which he proposes to graduate to the Dean of the Faculty of Medicine—

1. A declaration in his own handwriting that he has completed his twenty-first year, or that he will have done so on or before the day of graduation, under articles of apprenticeship to any surgeon or other master. (This declaration, along with a statement of studies, is appended to the schedule for the final examination, and must be signed before the schedule is given in.)

2. A statement of his studies, as well in literature and philosophy as in medicine, accompanied with proper certificates.

Each candidate is examined both in writing and *viva voce*—

1. Zoology, botany, physics, and chemistry.
2. On anatomy, physiology, and materia medica, and therapeutics.
3. On pathology, medical jurisprudence, and public health.
4. On medicine, surgery, and midwifery.

The examinations in anatomy, chemistry, physiology, botany, and zoology, materia medica, and pathology, are conducted, as far as possible, by demonstration of objects placed before the candidates.

Candidates who are ready to submit to an examination in the subjects comprised in the first division, viz., botany, zoology, physics, and chemistry, may be admitted to examination in all or any two of these subjects at any examination held after they have attended a full course in each of the subjects professed.

Candidates who have passed their examination in the subjects in the first division may go up for examination in those of the second division at the end of their third winter session, but may postpone their examination in materia medica and therapeutics until the close of the summer session following.

They may, in a similar way, go up for the subjects of the third division at the end of their fourth winter session, and may postpone their examination in medical

jurisprudence and public health until the close of the following summer session.

Candidates who have passed their examinations in the subjects comprised in the first, second, and third divisions may be admitted to examination in the fourth or final division, when they have completed the fifth year of study.

The degree of Doctor of Medicine may be conferred on any candidate who has obtained the degrees of Bachelor of Medicine and Bachelor of Surgery, and who is of the age of twenty-four years, and who produces a certificate of having been engaged, subsequently to his having received the degrees of M.B. and Ch.B., for at least two years in attendance on a hospital, or in scientific work bearing directly on his profession, or in the Military or Naval Medical Services, or in medical or surgical practice. The candidate shall submit to the Faculty of Medicine a thesis certified by him to have been composed by himself, and which shall be approved by the Faculty, on any branch of knowledge comprised in the professional examinations for the degrees of Bachelor of Medicine and Bachelor in Surgery, which he may have made a subject of study after having received those degrees. The candidate will also be examined in clinical medicine and in some of its special departments.

The regulations for the degree of Ch.M. are very similar, the candidate being examined in surgical anatomy, operations on the dead body, clinical surgery, and some of the special branches.

Candidates settled abroad, who cannot appear personally to receive the degree, may, after satisfying the Senatus to that effect, have the degree conferred on them *in absentia*.

Fees.—The fee to be paid for the degrees of Bachelor of Medicine and Bachelor of Surgery is twenty-two guineas and the proportion of this sum to be paid by a candidate at each division of the examination is registered from time to time in the University Court. The fee for the degree of Doctor of Medicine or of Master of Surgery is ten guineas.

The total expenses of the curriculum, including examination and matriculation fee, is about £146.

Bursaries and Scholarships open for Session 1899-1900. —Among the bursaries and scholarships open during the ensuing year are:—Two Sibbald Bursaries of £30 a year for three years, particulars from Messrs. Mackenzie, Innes and Logan, W.S., 23, Queen St., Edinburgh, before September 15th. Two Thomson Bursaries of £25 for four years, one conferred at each preliminary examination in October and March. Five Grierson Bursaries, natives of Crawford and Leadhills, have a preference. Names must be sent in before September 17th. Two John Aitken Carlyle Bursaries of £28 one year for proficiency in class examinations in anatomy and chemistry or physiology. Two Mackenzie Bursaries of £20 in practical anatomy. Renton Bursary of £20, for one year, for students attending classes of natural physiology, mathematics, chemistry, or political economy, who also can show they are in need of pecuniary aid. Names to be sent to secretary before the middle of September. Two Crichton Bursaries of £50, for four years, one competed for at each preliminary examination. Stark Scholarship in Clinical Medicine, of about £100, awarded in July, 1900; Murchison Memorial Scholarship, of the interest from £1,000, to take place in London in the summer of 1900; Buchanan Scholarship, of £40 10s., for proficiency in midwifery and gynaecology, as shown by class work and in the final examination. Other scholarships are:—The James Scott, £42 10s., annually, in midwifery; the Thomson, £40 for four years, in botany, zoology, and elementary mechanics in October; the Ettles, £31 5s. annually, to the most distinguished graduate; two Hope Prizes, £30 annually, in chemistry; two Crichton, £100 annually, in anatomy and physiology.

Full particulars of these and of the other prizes may be found in the "University Calendar" (published by Mr. Thin, South Bridge, Edinburgh, price 3s., post free, 3s. 6d.), or the "Medical Programme" (price 2d.) from the same publisher.

Graduation in Science.—The University of Edinburgh also possesses a Faculty of Science which may confer two

degrees, Bachelor of Science (B.Sc.) and Doctor of Science (D.Sc.). These degrees are given in pure science and in applied science. Candidates for the degree of B.Sc. in pure science must attend at least seven courses of instruction in the subjects selected by them during the course of not less than three academical years. Three of these courses must be on subjects prescribed for the first science examination, and four on those for the final examination. Four of these courses must be taken in the University of Edinburgh. Among the subjects recognised are chemistry, human anatomy, physiology, zoology, and botany. Graduates as B.Sc. may, after five years, proceed to the degree of D.Sc., undergoing an examination in the subjects chosen, and presenting a thesis founded on original work.

Graduation in Public Health.—Similar degrees are conferred in Public Health. Candidates must be graduates in medicine of a university recognised by the University Court, and must matriculate for the year in which they appear for examination. Before proceeding to the first examination they must produce evidence that (1) they have worked for at least twenty hours a week during a period of not less than eight months, after taking their medical degree, in a recognised Public Health Laboratory. Five of these months must be spent consecutively in the Public Health Laboratory of the University of Edinburgh and (2) have attended a course of lectures on physics, and one, of at least three months' duration, on geology, such as the Senators may approve of.

Candidates for the second examination for B.Sc. in Public Health are not admitted until at least eighteen months have elapsed after having passed M.B., Ch.B., or sooner than six months after the first examination. They must have attended two separate courses of Public Health, or at least forty lectures in each, one dealing with medicine, the other with engineering, each in its relation to public health, in such manner as the Senatus shall determine. They must also have studied practical sanitary work under a Medical Officer of Health for six months, have had three months' clinical instruction in a recognised fever hospital and three months' instruction in mensuration and drawing.

Full details of the subjects included in the different courses are given in the official programme of the Faculty of Science, which may be obtained from the University (price 2d.).

In a similar manner to that described under degrees in pure science, a B.Sc. may after five years proceed to take the degree of D.Sc. in Public Health.

Fees for Science Degrees.—B.Sc., first examination, £3 3s.; B.Sc., second examination, £3 3s.; D.Sc., £10 10s.; total, £16 16s.

University Hall, Edinburgh.—In an educational number it is worth while to call attention to the advantages now offered to students coming to Edinburgh to study, in the shape of social residences akin to though very much less pretentious than, the English University Colleges. During the past six years several buildings have been acquired in Edinburgh for this purpose, in which students can live in a self-governing community. In each house there are private studies with or without bedrooms, and common sitting and dining rooms. The charges vary from 7s. 6d. to 22s. 6d. per week. The residents elect a treasurer from among their number, who acts as intermediary between them and the housekeeper or servants. It is a satisfactory indication of the comfort of the Hall that several graduates now live in it and are willing to help or coach the undergraduates for moderate fees. To gain admission two references must be produced from past or present residents. These are considered and voted on at a house meeting. In all disputed points Professor Geddes is the referee, while Dr. Ricardo Stephens is the rent treasurer, who will supply any further information required. The Hall is an admirable place for parents to send their sons to. Any unruly member may be expelled by a meeting of the residents similar to that held for elective purposes.

Medical School for Women in Edinburgh.—The Medical Teaching of Women in Edinburgh is carried on by the Scottish Association for the Medical Education of Women (the Secretary, Minto House, Chambers Street). The classes are conducted by the lecturers of the Medical

School of the Royal Colleges, and qualify both for the Edinburgh University degree and for the Licence of the Triple Board. The classes are for women alone. The University of Edinburgh does not recognise certificates presented by female candidates for mixed classes without special cause shown.

ROYAL MEDICAL SOCIETY, EDINBURGH.—Students commencing their medical studies in Edinburgh should not neglect to join this fine old Society. It still fulfils the purpose for which it was founded as far back as 1737; namely, to facilitate intercourse between medical students of different years of study, to afford them the use of a large medical and scientific library, and to promote the discussion of medical matters apart from the supervision of the professors or teachers. The post of Senior President of this Society is one of the highest honours to which an Edinburgh student may attain. The list of eminent men in the profession who have filled the presidential chair from time to time would be hard to parallel. Intending members should apply to the sub-librarian at the Society's Hall, 7 Melbourne Place, Edinburgh. The annual subscription is two guineas. Payment of eight guineas at once renders the student a life member.

UNIVERSITY OF GLASGOW.

The University of Glasgow is both a teaching and an examining body, but admits to examination only those candidates whose course conforms to its own regulations. Within certain limits provision is made for accepting instruction given by recognised medical schools and teachers; but eight of the subjects other than clinical must be taken in this or some other recognised University entitled to confer the degree of M.D., and at least two years of the course must be taken in Glasgow University. Under the new regulations, laid down in Ordinance No. 14, Glasgow No. 1, of the Commissioners under the Universities (Scotland) Act, 1889, four degrees, open both to men and to women, are conferred—M.B. and Ch.B. (always conjointly), M.D., and Ch.M. A preliminary examination must be passed in (1) English, (2) Latin, (3) Elementary Mathematics, and (4) Greek, French, or German, with possible options to students whose native tongue is not English in the case of the fourth subject, and on passing students must register in the books of the General Medical Council. By a regulation recently enacted, it is no longer compulsory to pass in all the four preliminary subjects at once, and they may now be passed at two stages. For M.B. and Ch.B. a curriculum of five years is required.

The fees for M.B. and Ch.B. are £23 2s., and the present fee for hospital attendance is £21. The fee for M.D. is £10 10s., and for Ch.M. is £10 10s.

Bursaries and prizes to the annual amount of about £900 are appropriated to medical students, including an Arthur bursary for women, £25 for three years.

Several bursaries open to students in any faculty are not infrequently held by medical students, and scholarships and fellowships to the annual amount of £1,600 may be held by medical students who have gone through the Arts course.

QUEEN MARGARET COLLEGE FOR WOMEN.—Founded in 1883 (by the Glasgow Association for the Higher Education of Women, which was formed in 1877 with the object of bringing university instruction, or its equivalent, within the reach of women), Queen Margaret College in 1890 added to its Faculty of Arts a School of Medicine for Women. This was organised entirely on university lines, and with the view of preparing for university degrees: and when, in 1892, in consequence of the Ordinance of the University Commissioners authorising the Scottish Universities to admit women to instruction and graduation, Queen Margaret College became the Women's Department of the University of Glasgow, its classes in medicine taken previously to its incorporation with the University were recognised as preparing for the degree. A full course of study for M.B.Ch.B. is given, with excellent facilities for hospital and dispensary work. A Hall of Residence for the students was founded four years ago.

UNIVERSITY OF ABERDEEN.

The University of Aberdeen possesses under its charters

the amplest privileges claimed or enjoyed by any academical institution. It confers degrees in the five faculties of Arts, Science, Divinity, Law, and Medicine. It also grants diplomas in Public Health, Agriculture, and in Education. It is, moreover, a teaching body, equipped with twelve distinct chairs in the various branches of medicine and surgery, besides a Lectureship in Tropical Medicine. The majority of the professors devote their whole time to the work of the chairs. There are fully-equipped laboratories, the accommodation for which has recently undergone considerable extension. The degrees of M.B. and Ch.B. are conferred together; they cannot be obtained separately. The curriculum of study is nearly the same as in the University of Edinburgh; the regulations in the preceding columns will therefore apply here. Two years must be passed at Aberdeen. With regard to fees, each candidate for the degrees of M.B. and Ch.B. must pay a fee of £5 5s. in respect of each of the first three professional examinations, and £7 7s. for the final examination. Class fees, £3 3s. each. Total cost, exclusive of the fees for degrees is about £100. Besides the Royal Infirmary, students have the opportunity of attending several other local institutions where special courses of instruction are given. Perpetual fee for hospital practice is only £6. The professional examinations are held twice in each year, namely, in March and July, directly after the close of the winter and summer sessions. Through the liberality of the late Dr. Charles Mitchell, students will be privileged to commence work in the coming session in the magnificently equipped extension buildings of the University.

BURSARIES.—Bursaries, Scholarships, and Fellowships, to the number of forty-two, and of the annual value of over £1,600, may be held by students of medicine. See University Calendar.

THE DEGREE OF M.D.—The degree of Doctor of Medicine may be conferred on any candidate who has obtained the degrees of M.B. and Ch.B. (Old Regulations), is of the age of twenty-four years, and has been engaged subsequently to his having received the degree of M.B. for two years in attendance in a hospital, or in military or naval medical service, or in medical or surgical practice, and has presented a thesis which has been approved of by the Medical Faculty. Candidates for the degree of M.D. (New Regulations) are required to pass an examination in clinical medicine in addition to presenting a thesis. Similar regulations apply to a degree of Ch.M. (Master of Surgery).

A Diploma in Public Health is conferred after examination on graduates in medicine of any university in the United Kingdom.—Regulations may be seen in the Calendar, or obtained on application to the Secretary of the Medical Faculty.

ABERDEEN ROYAL INFIRMARY.—This is a well equipped institution, containing 240 beds, and affords excellent opportunities for clinical study to students at the Aberdeen University. The city, moreover, offers inducements in the way of cheaper living and comparative quiet to that obtained in Edinburgh and Glasgow, and will doubtless be preferred by some on this account.

ST. ANDREW'S UNIVERSITY.

UNITED COLLEGE ST. ANDREWS AND UNIVERSITY COLLEGE, DUNDEE.

This University (session opens October 11th) grants the degrees of M.B., Ch.B., M.D., and Ch.M., and also a diploma in Public Health. The degrees of the University are open to either sex. For the degree of M.B., Ch.B. two of the five years of medical study must be spent in the University of St. Andrews; the remaining three may be spent in any University of the United Kingdom, or in any foreign, Indian, or Colonial University recognised for the purpose by the University Court, or in such medical schools or under such teachers as may be recognised for the purpose by the University Court. The preliminary examination and the professional examinations are of the same character as in the other Scottish Universities.

University College, Dundee, was affiliated and made to form part of the University of St. Andrew's on January 15th, 1897, and the whole medical curriculum may be

taken in the college. The United College, St. Andrews, offers classes for the first two years of professional study.

BURSARIES AND SCHOLARSHIPS.

UNITED COLLEGE, ST. ANDREWS.—Two Berry bursaries of £40 tenable for three years, open to men for arts, science, or medicine. Twelve Berry bursaries of £20 tenable for two years open to men only proceeding to graduate in medicine. Candidates must reach the standard necessary to entitle them to pass the medical preliminary examination of the university. Fourteen Taylor-Thompson bursaries £20 to £30 tenable for one year, partly for two, open to women only proceeding to graduate in medicine.

UNIVERSITY COLLEGE, DUNDEE.—Eleven entrance bursaries of £15 open to men or women for arts, science, or medicine, tenable for one year. Four £20 and three £15 second year bursaries for men or women in art, science, or medicine, tenable for one year. Four £20 and two £15 third year bursaries for men or women in arts, science, or medicine, tenable for one year. Two Educational Trust Bursaries of £25, tenable for three years. Applicants must have attended a public or state aided school in Dundee for at least one year before examination. Bute Bursary annual income from £1,000 (men only).

PRELIMINARY EXAMINATIONS.—The dates of the next two examinations are September 30th, 1899, and March 24th, 1900. Schedules (obtainable from the Secretary of the University) to be returned filled up, and fees paid by September 15th, 1899, on March 10th, 1900.

Fees for Degrees.—Total fees for M.B., Ch.B., are the same as at other Scottish Universities, i.e., 22 guineas (payable in instalments). Fee for the degree of M.D., and also for that of Ch M., is ten guineas in each case. For the Diploma of Public Health examinations the fee is £5 5s. for each of the two examinations. The diploma is granted on special examination to graduates in medicine of any University of the United Kingdom.

UNITED COLLEGE, ST. ANDREWS.—*Class Fees*—The fee payable in each of the following separate classes is three guineas, viz., in Chemistry, Practical Chemistry, Physics, Zoology, Botany, Physiology, Practical Physiology, Anatomy, Practical Anatomy, Materia Medica, and Practical Pharmacy.

UNIVERSITY COLLEGE, DUNDEE.—*Class Fees.*—The fee payable in each of the following separate classes is 3 guineas, viz., in Chemistry, Practical Chemistry, Physics, Zoology, Botany, Physiology, Anatomy, Practical Anatomy, Materia Medica, Practical Pharmacy, Pathology, Practical Pathology, Bacteriology, Medical Jurisprudence and Public Health, Medicine, Surgery, Operative Surgery, and Midwifery.

In Clinical Medicine, Clinical Surgery, Ophthalmology and Mental Diseases, the class fees are 2 guineas each, and in Fevers 1 guinea. For the Chemistry required for the D.P.H. the fee is 7 guineas. A special class is also held for the D.P.H., for which the fee is 3 guineas.

DUNDEE ROYAL ASYLUM.—The appointments include a qualified resident assistant and two resident clinical clerks. Clinical instruction is given.

Further information will be found in the Calendar of the University, published by Messrs Blackwood and Sons, Edinburgh, or can be had of the Dean of the Medical Faculty, Professor Waymouth Reid, F.R.S.

DUNDEE ROYAL INFIRMARY.—The Infirmary contains 286 beds, with a special ward for the treatment of children. Three resident qualified assistants are appointed annually. Clinical clerks and dressers are attached to the physicians and surgeons, and students are appointed to assist in the post mortem room. Out patients are seen daily at 9 a.m. The instruction given at the Infirmary is recognised for purposes of graduation by the Scotch Universities, the University of London, the Royal University of Ireland, and by the Royal Colleges of England and Scotland. Hospital ticket for the Infirmary £2 2s. each session, or £3 3s. 0d. a year. Further information on application to the Medical Superintendent.

THE COLLEGES.

The Royal College of Physicians of Edinburgh, the Royal College of Surgeons of Edinburgh, and the Faculty

of Physicians and Surgeons of Glasgow have made arrangements by which, after a series of examinations, the student may obtain the diplomas of the co-operating bodies.

The holders thereof are enabled to register three diplomas under the Medical Acts, viz., Licentiate of the Royal College of Physicians of Edinburgh, Licentiate of the Royal College of Surgeons of Edinburgh, and Licentiate of the Faculty of Physicians and Surgeons of Glasgow. The diplomas are also recognised by the Army, Navy, and other public bodies.

The three co-operating bodies grant their single qualifications only to candidates who are already registered as possessing another and opposite qualification in medicine or surgery, as the case may be.

REGULATIONS OF THE CONJOINT BOARD OF THE ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH AND THE ROYAL COLLEGE OF SURGEONS OF EDINBURGH AND THE FACULTY OF PHYSICIANS AND SURGEONS, GLASGOW.—The candidate must produce certificates of having attended the following separate and distinct course of lectures, the certificate distinguishing the sessions and the schools in which the courses were severally attended. Anatomy, one course, six months. Practical anatomy, twelve months. Chemistry, one course, six months. Practical or analytical chemistry, one course, three months. Materia medica, one course, three months. Physiology, one course, six months. Practice of medicine, one course, six months. Clinical medicine, nine months. Principles and practice of surgery, one course, six months. Clinical surgery, nine months. Midwifery and diseases of women and children, one course, three months. Medical jurisprudence, one course, three months. Pathological anatomy, one course, three months. The candidates must also produce the following certificates:—(a) Of having attended not less than six cases of labour under the superintendence of the practitioner who signs the certificates, who must be a registered medical practitioner. (b) Of having attended, for three months, instruction in practical pharmacy. The certificate to be signed by the teacher, who must be a member of the Pharmaceutical Society of Great Britain, or the superintendent of the laboratory of a public hospital or dispensary, or a registered practitioner who dispenses medicine to his patients, or a teacher to a class of practical pharmacy. (c) Of having attended for twenty-four months the medical and surgical practice of a public general hospital, containing on an average at least eighty patients, and possessing distinct staffs of physicians and of surgeons. (d) Of having attended, for six months, the practice of a public dispensary specially recognised by any of the co-operating bodies; of having been engaged for six months as visiting assistant to a registered medical practitioner. (e) Of having been instructed in vaccination.

First Examination, Fee £5.—The first examination shall embrace chemistry, embracing the following particulars:—Chemical physics, heat, light, and electricity, the principal non-metallic and metallic elements, and their more common combinations, also the leading alcohols, organic acids, ethers, carbohydrates, and alkaloids; the candidate will also be examined practically in testing; physics and elementary biology. The first examination shall take place not sooner than the end of the first year, including a winter and summer session. Candidates who desire to enter for the first professional examination must apply to the Inspector of Certificates on or before the Friday preceding the day of examination, and must produce certificates of attendance on one course of chemistry, one course of practical chemistry, one course of anatomy, and six months' practical anatomy.

Second Examination, Fee £5.—The second examination shall embrace anatomy and physiology, and shall not take place before the termination of the summer session of the second year of study. Candidates must produce to the inspector certificates of attendance on the prescribed courses of anatomy, practical anatomy, and physiology.

Third Examination, Fee £5.—Comprises the subjects of pathology, materia medica, and pharmacology and advanced anatomy.

Final Examination, Fee £15.—The final examination shall embrace the principles and practice of medicine (including therapeutics and medical anatomy, clinical medicine); the principles and practice of surgery, (including surgical anatomy and surgical pathology); clinical surgery; midwifery and gynecology, medical jurisprudence and hygiene; and shall not take place before the termination of the full period of study.

Subject of Preliminary Education.—(1) English language, including grammar and composition; (2) Latin, including grammar, translation from specific authors, and translation of easy passage not taken from such authors; (3) elements of mathematics, comprising (a) arithmetic, including vulgar and decimal fractions; (b) algebra, including simple equations; (c) geometry, including the first two books of Euclid; (4) elementary mechanics of solids and fluids, comprising the elements of statics, dynamics, and hydrostatics; (5) one of the following optional subjects:—(a) Greek; (b) French; (c) German; (d) Italian; (e) any other modern language; (f) logic; (g) botany; (h) zoology; (i) elementary chemistry.

Qualification in Public Health.—The College of Physicians, in association with the Royal College of Surgeons of Edinburgh and the Faculty of Physicians and Surgeons of Glasgow, confers a certificate of competency in public health. The examinations are held in April and October. Fee, £10 10s.

For the special regulations of the Royal College of Surgeons of Edinburgh, intending candidates should apply to Mr. James Robertson 48, George Square, Edinburgh, and for those of the Royal College of Physicians, to Dr. R. W. Philip, 45, Charlotte Square.

The Fellowship of the Royal College of Physicians of Edinburgh is conferred only by election, and the candidate must have been a member of the college for at least one year previously, and have attained the age of twenty-five years.

The membership is conferred only on licentiates of the college or graduates of a British or Irish university after an examination in medicine and therapeutics, and in any other branch of medical science to be selected by the candidate. Under certain conditions as to age and professional standing, candidates may, however, be admitted without examination to the licence of R.C.P.Ed.

The licence, or single qualification in medicine, is conferred on candidates who already possess a recognised qualification in surgery. The examinations of this licence are held on the first Wednesday of each month, save those of September and October, on medicine, materia medica, midwifery, and medical jurisprudence. The fee is £15 15s., and intending candidates should communicate with the Secretary of the College at least eight days before the date of examination.

The Fellowship of the Royal College of Surgeons of Edinburgh is conferred (except under certain conditions as to age and professional standing), only on candidates who have passed a special examination, and have previously obtained a diploma from the college, or from either of the Colleges of Surgeons of England or Ireland, or the Faculty of Physicians and Surgeons of Glasgow, or the surgical degrees of the Universities of Great Britain, and who are twenty-five years of age. The subjects for examination for those who are already Licentiates of the College are on the principles and practice of surgery, clinical and operative surgery, and one optional subject.

Those who are not Licentiates of this College: on principles and practice of surgery, clinical and operative surgery, surgical anatomy, and one optional subject; and in such supplementary subjects as have not, in an adequate manner, been included in the examination for the registrable surgical qualification possessed by such candidates and which are required in the examination for Licentiates of this College.

The optional subjects shall embrace: (a) Surgery, special branches; (b) advanced anatomy and physiology; (c) surgical pathology and morbid anatomy; (d) midwifery and gynecological medicine and surgery; (e) medical jurisprudence and hygiene; (f) practice of medicine and therapeutics. The examinations are written, oral, and practical. Three weeks' notice must be given to Mr.

James Robertson, from whom full particulars as to certificates required may be obtained. The fee is £30 for those who hold the diploma of Licentiate of the College, and £45 to others (no stamp duty is payable on the diploma). Registered practitioners, aged not less than 40, who have been in practice for not less than ten years, and who have highly distinguished themselves by original investigations, may under special circumstances be elected without examination. Women are not admitted to the Fellowship.

LICENCE.—The examination embraces the principles and practice of surgery (including operative surgery and surgical pathology), clinical surgery, and surgical anatomy, and shall not take place before the termination of the full period of study. Fee £15 15s.

DENTAL DIPLOMA.—Every candidate for the dental diploma must have attended the general lectures and courses of instruction required at a university or an established medical or dental school recognised by the College as qualifying for the diploma in surgery. The fee is £10 10s.

EDINBURGH ROYAL INFIRMARY.—Clinical instruction is afforded at this institution, which contains 780 beds in the building, and 10 beds in a convalescent home, under the supervision of professors of the university and the ordinary physicians and surgeons of the infirmary. Special instruction is given on diseases of women, physical diagnosis, and diseases of the eye, ear, throat, and teeth. Separate wards are devoted to venereal diseases, diseases of women, diseases of eye, also to cases of incidental delirium or insanity, and three wards are specially set apart for clinical instruction to women students. Post-mortem examinations are conducted in the anatomical theatre by the pathologists, who also give practical instruction in pathological anatomy and histology. The perpetual fee, on one payment, £12; the annual fee, £6 6s.; half-yearly, £4 4s.; quarterly, £2 2s.; monthly, £1 1s. Separate payments amounting to £12 12s. entitle the student to perpetual ticket. No fees are payable for any surgical or medical appointment.

The appointments are as follows:—

1. Resident physicians and surgeons are appointed, and live in the house free of charge. There is no salary. The appointment is for six months, but may be renewed at the end of that period by special recommendation.

2. Special non-resident clerks (in the special subjects, and for out-patient work) are appointed for six months. These also may be similarly renewed.

3. Clerks and dressers are appointed by the surgeons and physicians. Those are open to all students and junior practitioners holding hospital tickets.

4. Assistants in the pathological department are appointed by the pathologists to conduct post-mortem examinations in the anatomical theatre.

SCHOOL OF MEDICINE OF THE ROYAL COLLEGES, EDINBURGH.—This school, established in 1505, is constituted by over fifty lecturers especially licensed by the colleges.

The lectures qualify for the University of Edinburgh, and other Universities, the Royal Colleges of Physicians and Surgeons of Edinburgh, London, and Dublin, and the other medical and surgical boards.

The minimum cost of the education in the School of Medicine for the triple qualifications of physician and surgeon from the Royal Colleges of Physicians and Surgeons of Edinburgh and the faculty of Physicians and Surgeons of Glasgow, including the fees for the joint examinations, is about £115, which is payable by yearly instalments during the period of study.

The Winter Session opens October 2nd. [The secretary, Mr. R. N. Ramsay, 24, Forrest Road, Edinburgh, will forward the School Calendar *gratis* to inquirers.]

ST. MUNGO'S COLLEGE AND GLASGOW ROYAL INFIRMARY.—This college was incorporated in 1889 under its new title, being formerly known as the Glasgow Royal Infirmary School of Medicine. The Medical Faculty occupies buildings erected for the purposes of the medical school in the grounds of the hospital, and the laboratories, museums, and lecture rooms are of the most approved description. Attendance on the classes in St. Mungo's College qualifies for the medical degrees of the Universities and the medical and surgical colleges in accordance with their regulations.

The Royal Infirmary, which is at the service of the College for teaching purposes, is one of the largest general hospitals in the kingdom. It has 612 beds available for clinical instruction, including an ophthalmic department, and it has special wards for diseases peculiar to women, for venereal diseases, erysipelas, burns, and diseases of the throat. At the dispensary special advice and treatment are given in diseases of the eye, ear, teeth, and skin, in addition to the large and varied number of ordinary medical and surgical cases—about 44,000 per annum—which in a great industrial centre daily require attention. Students at the college and hospital get the benefit of dispensary experience free of charge, and no better or wider field for seeing hospital practice and receiving clinical experience can be found than in the Glasgow Royal Infirmary.

Appointments.—All appointments are open. There are five physicians and seven surgeons' assistants who obtain free board and residence in the hospital and act in the capacity of house physicians and house surgeons, and there is an assistant to the gynaecologist who boards but does not reside in the hospital. There is also a house surgeon for the ophthalmic department. These appointments are made for six months, and are open to gentlemen who have a legal qualification in medicine and surgery. Clerks and dressers are appointed by the visiting physicians and surgeons. From the large number of cases of acute diseases and accidents of varied character received, these appointments are valuable to students. In the pathological department assistants are also appointed by the pathologist.

Fees.—The fees for Lectures, including Hospital attendance necessary for candidates for the Diplomas of the English, Scotch, and Irish Colleges of Physicians and Surgeons, amount to £72.

ANDERSON'S COLLEGE MEDICAL SCHOOL, GLASGOW.—New and excellently equipped buildings were opened in October, 1877, in Dumbarton Road, immediately to the west of the entrance to the Western Infirmary and within four minutes' walk of the university. Extensive laboratory accommodation is provided for practical anatomy, practical chemistry, practical botany, practical zoology, practical physiology, practical pharmacy, operative surgery, and hygiene and public health. There are also provided a library and reading room, and a students' recreation room. The buildings are constructed upon the most approved modern principles. The dissecting room is open in winter from 9 a.m. to 6 p.m., and in summer from 6 a.m. to 6 p.m. These students are assisted in their dissection by the professor and demonstrators, by whom daily examinations and demonstrations on the parts dissected are conducted. The supply of subjects is ample, and students are consequently provided with parts as soon as they may be ready for them. The dissecting room is provided with a complete series of dissected specimens mounted in plaster of Paris illustrating the anatomy of the human body. There is also a large Bone Room furnished with complete sets of painted and unpainted bones.

Dental Curriculum.—Students studying with a view to the dental diploma can obtain instruction in the following subjects:—Physics, chemistry, anatomy, physiology, surgery, practice of medicine, and materia medica. The special dental courses may be obtained in the Dental School, 5, St. Vincent Street, Glasgow.

Fees.—Fees for hospital practice and clinical lectures, first year, £10 10s.; second year, £10 10s.; afterwards free. For six months, £3 6s.; three months, £4 4s. Students who have paid 20 guineas at another hospital for its perpetual ticket are admitted six months for £2 2s.; or one year for £3 3s. Vaccination certificate, recognised by Privy Council, £1 1s.

POST-GRADUATE COURSES IN SCOTLAND.

In Edinburgh a number of permanent post-graduate courses continue more or less continuously throughout the year. Among those open to or especially for post-graduates are:—

1. Ophthalmology: daily at the Royal Infirmary. 2. Ophthalmoscopy: Dr. George Mackay, Eye Dispensary, Chambers Street, fee £2 2s.; Dr. W. G. Sym, Eye, Ear, and Throat Infirmary, Cambridge Street, fee £2 2s. 3. Aural Surgery, &c.: Dr. MacBride and assistants, Royal Infirmary; Dr. Hunter Mackenzie, Eye, Ear and Throat
